When the ground is in proper readineſs for planting, ſtretch along a ſtraight ſide of the field, at fifteen or twenty feet diſtance from the hedge, and parallel to it, a line with knots or rags tied in it, as far aſunder as you deſign your hills to be, and ſtick in the ground a ſharp-pointed ſtick at every knot, as marks for the places where the hills are to be made: continue the line in this manner the whole length of the ground, and from this firſt row you may mark out the reſt of the field, either in ſquares, chequer-wiſe, at the intended diſtance of the hills, or in the quincunx form, where the hills of every row lie oppoſite to the middle of the firſt, in a triangular from.

The diſtance of the hills ſhould be, in ſome meaſure, regulated by the nature and goodneſs of the ſoil: but, in every caſe, they ſhould be far enough aſunder to admit the hoe-plough at all times without danger to the plants. If the ſoil be dry and ſhallow, ſix or ſeven feet will be a convenient diſtance: but if it be rich, moiſt, and apt to bear large hops and leaves, it may be right to allow eight or nine feet between the hills.

The moſt proper ſeaſon for planting hops is from the beginning of March to near the middle of April, at the time when they begin to ſhoot. The Kentiſh huſbandmen approve likewiſe of October: but the common ſorts are not to be procured then, unleſs it be from a ground that is to be dug up and deſtroyed; beſides which, there is ſome danger of their rotting in the earth, if the winter ſhould prove very wet.

There are ſeveral ſorts, though the botaniſts allow but one ſpecies, of hops. The moſt eſteemed are, the long white, the oval, and the long ſquare garlic hop. Theſe differ from each other in the colour and ſhape of their bells, or hops, in their degree of bearing, and in their time of ripening. The long white is moſt valued, becauſe it is a great bearer, and produces the moſt beautiful hops; for the beauty of hops conſiſts in their being of a pale bright green colour. The oval hop is beautiful, but does not yield ſo large a crop. There is a ſort of this kind of white hop, called the early, or rath hop, which ripens a week or ten days before the common, and is therefore of advantage to thoſe who would be firſt at market: but it is tenderer than the other, and does not bear near ſo plentifully. The long ſquare garlic hop is the greateſt bearer, more hardy, and ſomewhat later ripe than the former; but by reaſon of its redneſs towards the ſtalk, it is not ſo beautiful to the eye, and therefore is not ſo much eſteemed as the other ſorts.

Few hop grounds are without ſome plants of a ſort of hop which many call the female hop, but very erroneouſly; for the female hop is that which is cultivated for uſe, and this, which others name more properly the wild hop, is the male. Towards the middle of July, it puts out a great number of long looſe bunches of ſmall flowers, not at all like the true hop; and in ſomewhat leſs than a month after, that is to ſay, juſt before the true hop begins to bloſſom, they ripen, and with the leaſt motion of the wind, ſhed a farina, which is wafted all around, and is by ſome, not improbably, thought to be of uſe to impregnate other hops. Thoſe who are of this opinion adviſe therefore to leave one or two hills of them ſtanding in the hop-ground. But the common practice is to mark them at their firſt appearance, and to root them out afterwards, becauſe they do not bear bells or hops, and as they are generally the ſtrongeſt plants, ſets might otherwiſe be taken from them by miſtake.

There is alſo a poor ſtarved hop, called a wild hop, which is not judged to be a diſtinct ſort, but a hop which has degenerated for want of culture.

The planter of hops ought to be extremely careful in the choice of his plants, or ſets, particularly in regard to the kind of the hop: for it is a great trouble and loſs to him when his garden proves to be a mixture of ſeveral ſorts of hops, ripening at different times. He who plants the three ſorts above-mentioned, viz. the early, the long white, and the ſquare hop, in three diſtinct parts of his ground, will have the conveniency of picking them ſucceſſively as they become ripe.

Hop-ſets are cuttings from the roots or branches which grow from the main root or ſtock. They ſhould be procured, if poſſible, from grounds planted with none but the ſort which is deſired; and they ſhould be from five to ſeven or eight inches long, with three or more joints or buds on them, all the old bind and hollow part of the ſet being cut off.

The ground being prepared for planting, as before directed, towards the latter end of February, or in the beginning of March, if the ſoil be light, or late in March if it be ſtrong and moiſt, make, in the places marked out by the ſticks ſtuck in them, holes about twelve or ſixteen inches wide, and of a depth proportioned to the nature of the ground. In general, ten or twelve inches will be a ſufficient depth. If the ground be ſhallow, and you meet with hard clay or gravel, by no means enter into this, for you would then make a baſon to retain water; but, in ſuch caſe, inſtead of going deeper, raiſe up a ſmall hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half or two feet deep, and you will find the hops thrive the better; for their tap roots naturally run downward.

When all things are ready for planting, fill up the holes with the mould before thrown out of them, if it be naturally good, after having firſt broke it fine with a ſpade: but if the ſame earth be not rich enough, make uſe of fine freſh mould, or of the compoſt provided for this purpoſe. About a peck or two of this will be ſufficient for each hill; but no new dung ſhould be put into the hole on any account.

Then, with a dibble or ſetting ſtick, ſuch as gardeners generally uſe for planting of beans, make five or ſix holes, the depth of your ſets, one in the middle, perpendicular, and the reſt round about, ſloping, and meeting at the top near the center: put your ſets therein, ſo that they may ſtand even with the ſurface of the ground; and then preſs the mould cloſe to them, and cover them with fine mould two or three inches thick. A ſtick ſhould be placed on each ſide of the hill to ſecure it.

The ground being thus planted, all that is to be done in the following ſummer, is to keep the hills and alleys clear from weeds by frequent hoeings; to dig the ground in the month of May, and to carry off all the ſtones that are turned up by digging; to raiſe a ſmall hill about the

plants; to throw ſome fine mould on their roots; and in the latter end of May, or beginning of June, to twiſt all the vines and branches together into a bunch or looſe knot, and lay them thus twiſted on the top of the hill.

Towards the latter end of February, or in the beginning of March, in the ſecond year, when the weather is kindly, open the hills, and with a ſharp knife, cut off the ſhoots of the firſt year to within an inch of the old ſtock, together with all the younger ſuckers that have ſprung from the ſets, and cover the ſtock with fine earth. To keep the knife ſharp, you ſhould have a whetſtone always by you at dreſſing.

In the third and following years, when you dig your hop-ground in February, let the earth be taken away with a ſpade, or hoe, round about the hill, very near them, that you may the more conveniently come at the ſtock to cut it: then in fair weather, towards the beginning of March, if your hops be weak, begin to dreſs them; but if they are ſtrong, and in heart, the middle or latter end of March will be the beſt time; for late dreſſing reſtrains their too early ſpringing, which is the cauſe of many injuries to the hop.

After the hops are dreſſed in the ſecond year, the next buſineſs is to pole them. Poles of only ten or twelve feet long will do then; but in the third year, by which time they come to their full bearing ſtate, they will require poles of full ſize: this, if the ground be rich, and the hop vigorous, will be from ſixteen to twenty feet, or even more; or there will be danger of loſing great part of the crop.

If the hop be weak, and the ground not rich, the poles ſhould not be more than from fourteen to eighteen feet long, for fear of impoveriſhing the root; for the hop will ſoon run itſelf out of heart if over poled; ſo that, as was ſaid before, there is more danger in over-poling than in under-poling: neither can a good crop be expected from an over-poled ground, becauſe the branches which bear the hops grow very little till the buds have over-reached the poles, which they cannot do when the pole is too long. Two ſmall poles are ſufficient for a hill in a young ground.

Towards the latter end of July hops begin to bloſſom, about the beginning of Auguſt they bell, and in forward years, they are ſometimes ripe at the end of Auguſt, or beginning of September. When they begin to change colour, or are eaſily pulled to pieces, when they emit a fragrant ſmell, and when their ſeeds begin to look brown and to grow hard, you may conclude that they are ripe: then pick them with all expedition; for a ſtorm of wind will do them great miſchief at this time; and hops picked green and bright, without bruiſing or diſcolouring, will ſell for a third part more than thoſe that are otherwiſe.

When the poles are drawn up in order to be picked, the vines around them ſhould be cut aſunder at the height of about three or four feet from the ground; for the cutting of them lower, eſpecially while the hops are green, would occaſion ſo great a flowing of the ſap, as would weaken and hurt the root.

The moſt convenient way of picking them is into a long ſquare frame of wood, called a bin. This frame is made of two poles, or pieces of wood, each nine or ten feet long, and three or four inches broad, joined together at about a foot and a half from each end, by two other pieces three feet long; and it is ſupported by four legs three feet and a half high; ſo that there remain in the middle of it a ſpace ſix feet long, three wide, and three and a half deep. In this ſpace is fixed a coarſe linen cloth, or hop-bag, cut open on one ſide, and hung hollow, either by hitching it on tenter-hooks along the inſide of the frame, or by ſtretching it on the outſide with wooden ſkewers, to receive the hops as they are picked. Three men or women, or four boys or girls, may ſtand at each ſide of the frame, and pick two poles at a time.

The hops ſhould be picked as free as poſſible from leaves and ſtalks; for theſe would be of greater prejudice to the ſale, than any ſeeming advantage which might be expected from their weight. The bin ſhould be emptied two or three times a day into a large cloth of coarſe linen, in which the hops ſhould be immediately ſtitched up with ſkewers, and carried directly to the oaſt, or kiln, to be dried; for if they remain long in the bin, or cloth, they will ſweat and be diſcoloured; but if you cannot dry them immediately, and muſt keep them a little while, ſpread them on a floor, and by that means the damage which they will receive in a day or two will not be great.

In drying of hops, firſt lay the hair-cloth very even on the bed or floor of the kiln, and ſpread the green hops thereon, about ſix inches thick, laying them with a rake as ſmooth as poſſible, not thicker in one place than another. Let the kiln be moderately warmed before you lay on the hops; then keep an even and ſteady fire under them, but not too fierce at firſt, for fear of ſcorching them; and let not the fire ſlacken, but rather increaſe it till the hops are nearly dried, leſt the moiſture or ſweat, which the fire has raiſed, fall back and diſcolour the hops. After the hops have lain thus about ſeven, eight, or nine hours, have left off ſweating, and leap up when beaten with a ſtick, then turn them upſide with a broad malt ſhovel, or ſcoop made for that purpoſe, or caſt them up into a heap in the middle, and afterwards ſpread them equally on all ſides. Let them remain in this ſituation for two or three hours more, till every hop, if poſſible, be thoroughly and equally dried; and then with a hair-cloth, remove them to the heap where they are to lie till they are bagged.

Hops break all to powder if they are bagged hot from the kiln. To prevent this, they ſhould be laid in a heap, to ſweat and grow tough; and if they are then covered for a while cloſe with blankets, to keep the air from them, they will bag the better. There is no limited time for their ſweating; that varying according to the weather, three or four days are commonly ſufficient; but it is a certain rule, that when the hops feel moiſt and clammy, and can be ſqueezed in the hand, or trodden cloſe, without breaking, they are then fit for bagging. The harder they are trodden, the better they will keep.

The bags proper for this occaſion are made of coarſe linnen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about two hundred and a half weight of hops. The ſmall bags, called pockets, contain about half that weight.

The manner of bagging is thus: make a round or a ſquare hole, but a round one is moſt convenient, about twenty-ſix or thirty inches over, in the floor of the chamber where the hops are laid in heaps after they are ſweated. This hole ſhould be large enough to receive the bag, and for a man to go up and down it with eaſe. Tie with a piece of packthread an handful of hops in each lower corner of the bag, to ſerve as handles for the more eaſy lifting or removing of the bag; and, with packthread, faſten the mouth of the bag to a frame, or hoop, ſomewhat larger than the mouth of the hole, that the hoop may reſt on its edges, and ſtrong enough to bear the weight of the hops when the bag is full, and of the man who treads them. The upper-part of the bag being thus fixed by the hoop, let the reſt of it hang down through the hole; but not ſo near to the lower floor as to touch the ground: then throw into it a buſhel or two of hops; and let a man go into the bag, and with ſhoes that have no heels, tread the hops down on every ſide, as hard as he can, till they lie cloſe. Let more hops be then caſt into the bag, and be trodden down, as before; and continue this till the bag is full. When that is done, untie it from the hoop, let it down, and ſew up its mouth as cloſe as you can, obſerving at the ſame time to tie up ſome hops in the upper-corners, as was done before in the lower.—The harder the hops are preſſed, and the cloſer and thicker the bag is, the longer and better the hops will keep.

HOPPER, a kind of baſket, wherein the ſeed-corn is carried at the time of ſowing. See the article SOWING.

It is alſo uſed for the wooden trough, in a mill, into which the corn is put to be ground. See the article MILL.

HORARY, ſomething relating to an hour. Hence

HORARY, or HOUR-CIRCLE *of a Globe*, is a ſmall brazen circle, fixed upon the brazen meridian, divided into

into twenty four hours, having an index moveable round the axis of the globe, which upon turning the globe fifteen degrees, will ſhew what places have the ſun an hour before or after us. See GLOBE.

HORARY CIRCLES, or LINES, in dialling, are the lines or circles which mark the hours on the ſun-dials. See DIAL.

HORARY MOTION *of the Earth*, the arch it deſcribes in the ſpace of an hour, which is nearly 15 degrees, though not accurately ſo, as the earth moves with different velocities, according to its greater or leſſer diſtance from the ſun. See EARTH.

HORD, in geography, is uſed for a company of wandering people which have no ſettled habitation, but ſtroll about, dwelling in waggons, or under tents, to be ready to ſhift as ſoon as the herbage, fruit, and the preſent province is eaten bare: ſuch are ſeveral tribes of the Tartars, particularly thoſe who inhabit beyond the Wolga, in the kingdom of Aſtracan and Bulgaria.

A hord conſiſts of fifty or ſixty tents, ranged in a circle, leaving an open place in the middle. The inhabitants of each hord uſually form a military company or troop, the eldeſt of which is commonly the captain, and depends on the general or prince of the whole nation.

HORDEOLUM, *Crithe*, or *Barley-Corn*, ſo called from its reſemblance to that grain, in medicine, a tumor that grows in different parts of the eye-lids; it is commonly called a ſtye. When it is ſmall, it comes only on the edge of the eye lids, or very near it between the cilia; but when it is larger, it ſpreads towards the middle of the lid. In their beginning, an inflammation commonly accompanies theſe tumors: when they do not ſuppurate, their matter is concreted, and they become wens, which are ſometimes ſoft, and ſometimes very hard. Sometimes this diſeaſe diſappears a while, and afterwards returns in a few days.

The cure of this diſeaſe is ſuited to the different circumſtances that attend it. If there be an inflammation, the pulp of a roaſted apple applied by way of poultice ſoon diſperſes it, and ſometimes only abates the tumor. If it hardens, it muſt be opened with a lancet, and the hard fleſh conſumed by a liquid cauſtic, and afterwards the plaſter of the abbot de Grace applied.

If the hordeolum comes on the lower eye-lid, it is generally more on the inſide than the outſide, and is cured by the lapis infernalis, or rather by making an inciſion therein, drawing out the tumor and applying a collyrium of ten parts of water to one part of ſpirit of wine.

There are other little tumors on the edges of the eye-lids, which by reaſon of their whiteneſs and hardneſs are called chalazæ; as alſo, another ſort called lithiaſis or gravel-ſtone. All which are cured in the ſame manner. *St. Yves.*

HORDEUM, barley. See BARLEY.

HOREHOUND, *Marubium*, in botany. See MARUBIUM.

HORIZON, in aſtronomy, a great circle of the ſphere, dividing the world into two hemiſpheres, the one upper and viſible, the other lower and inviſible.

The word is Greek, ὁριζων, and derived from ὁριζω, to bound, terminate, or limit.

The horizon is either rational or ſenſible.

Rational, *True*, or *Aſtronomical* HORIZON, called generally the horizon, is a great circle, whoſe plane paſſes through the center of the earth, having the zenith and nadir for the poles thereof. It divides the ſphere into two equal parts, or hemiſpheres.

The meridian and vertical circles all cut the rational horizon at right angles, and into two equal parts.

Senſible, *Viſible*, or *Apparent* HORIZON, is a leſſer circle of the ſphere: this circle divides the viſible part of the ſphere from the inviſible, and has for its poles the zenith and nadir; conſequently the ſenſible horizon is parallel to the rational; and it is cut at right angles, and into two equal parts, by the verticals.

HORIZON, in geography, is a circle paſſing over the earth, and dividing the viſible part of the earth and heavens from that which is inviſible.

The altitude or elevation of any point of the ſphere, is an arch of a vertical circle, intercepted between it and the ſenſible horizon.

This is peculiarly denominated the ſenſible horizon, to diſtinguiſh it from the rational, or true, which paſſes through the center of the earth, as already obſerved.

The earth is ſo ſmall in compariſon of the immenſe largeneſs of the ſphere of the heaven, that the planes of the ſenſible and rational horizon may be taken as coincident; that is, the diſtance of them when meaſured in the ſphere of the heaven, is inſenſible, or however not great enough to be diſcovered by any obſervation. Let ABCD (plate LXXIV *fig.* 2.) repreſent the earth; *z h n o*, the ſphere of the ſtarry heaven: if an inhabitant of the earth ſtands upon the point A, his ſenſible horizon is *s e*, his rational horizon *h o*; the diſtance between the planes of theſe two is the ſemi-diameter A F of the earth, and is meaſured in a great circle upon the ſphere of the heaven, by the angle *e* F *o*, or by the arch *e o*; this arch, in ſo ſmall a circle as *z h n o*, would amount to ſeveral degrees, and conſequently the difference between the ſenſible and rational horizon would be great enough to be eaſily diſcovered by obſervation; but this circle in the figure is abundantly too ſmall to repreſent the ſphere of the heaven, proportional to ſuch an earth as is here ſuppoſed to be of the magnitude A B C D: let us therefore repreſent the ſphere of the heaven by a larger circle Z H N O; here the ſame ſemi-diameter of the earth A F, meaſured in this larger circle, amounts to fewer degrees; for the arch E O contains fewer degrees than the arch *e o*, and the angle E F O is leſs than the angle *e* F *o*; but this angle alſo might amount to ſeveral degrees and minutes, and be large enough to be meaſured by aſtronomical obſervation. From what has been ſaid, it follows, that the larger the ſphere of the heaven is, in proportion to the globe of the earth, the leſs ſenſible is the difference between the ſenſible and rational horizon, as being meaſured by a ſmaller angle, and conſequently, if we ſuppoſe the ſphere of the heaven ſo large that the angle which meaſured the diſtance between the ſenſible and rational horizon is not above a ſingle ſecond, the difference would be too ſmall to be meaſured by any aſtronomical inſtrument, and conſequently inſenſible: and thus, in fact, in the caſe at preſent, the earth, when compared with the ſphere of the fixed ſtars, becomes a point of no ſenſible magnitude.

The viſible horizon is moſt accurately obſerved upon the ſea, and is therefore, ſometimes, called the horizon of the ſea. It may be obſerved by looking through the ſights of a quadrant at the moſt diſtant part of the ſea within view. In making this obſervation, the viſual rays A D and A E (*fig.* 3.) will, by reaſon of the ſpherical ſurface of the ſea, always point a little below the true ſenſible horizon S S, and conſequently below the rational horizon H O, which is parallel to it, and coincident with it: how much the depreſſion of the horizon of the ſea is below the true horizon, is ſeen by the quadrant. It is obvious, that the higher the eye is, the greater is the depreſſion of the horizon of the ſea; this depreſſion is variable; ſo as to be ſometimes a little greater than at other times, though the height of the eye be the ſame in the ſeveral obſervations: this difference is but ſmall, amounting only to a few ſeconds, and is owing to the difference in the air, which at different times refracts the viſual rays more or leſs, according as it is of a greater or leſs denſity. The viſual ray, without refraction, is A E, and E is the moſt diſtant point which could be ſeen; but, by refraction, the ray F G coming from the point G, may be bent at F, ſo as to go on from thence in the right line F A, and then the view is extended as far as G, and the depreſſion of the horizon of the ſea is in the line A F, which points higher than A E, but extends the view farther.

A bare inſpection of the figure is ſufficient to ſhew that, if the refraction were greater, the view would be extended ſtill farther, as far as M, though the depreſſion of the horizon of the ſea would be leſs, as is ſhewn by the line A L M.

F. Lavel, profeſſor of hydrography at Marſeilles, found that the arch of the circumference of the earth intercepted between the obſervatory to the ſeaward and the horizon, fluctuated between fifteen minutes and thirteen minutes and a half: whence M. Caſſini deduces that the extent of the horizon is ſeven French leagues, of three miles each; and that the obſervatory is 175 feet high.

5 JA 59

HORIZONTAL, ſomething relating to the horizon; or that is taken in, or on a level with the horizon: thus we ſay, an horizontal plane, &c.

HORIZONTAL DIAL, that drawn on a plane parallel to the horizon, having its ſtyle elevated according to the altitude of the pole, in the place it is deſigned for. See the article DIAL.

HORIZONTAL DISTANCE. See the article DISTANCE.

HORIZONTAL LINE, in perſpective, a right line drawn through the principal point parallel to the horizon; or it is the interſection of the horizontal and perſpective planes. See the article PERSPECTIVE.

HORIZONTAL PARALLAX. See PARALLAX.

HORIZONTAL PLANE, that which is parallel to the horizon of the place, or nothing inclined thereto.

The buſineſs of levelling is to find whether two points be in the horizontal plane, or how much the deviation is.

HORIZONTAL PLANE, in perſpective, a plane parallel to the horizon paſſing through the eye, and cutting the perſpective plane at right angles.

HORIZONTAL PROJECTION. See the article PROJECTION and MAP.

HORIZONTAL *Range*, or *Level Range*, of a piece of ordnance, is the line it deſcribes, when directed parallel to the horizon.

Dr. Halley has given us the two following uſeful theorems:

1. A ſhot being made on an inclined plane, having the horizontal diſtance of the object it ſtrikes, with the elevation of the piece, and the angle at the gun between the object and the perpendicular, to find the greateſt horizontal range of that piece loaded with the ſame charge of powder, that is, half the latus rectum of all the parabolas made with the ſame impetus.—Take half the angle contained between the object and nadir, and the difference of the given angle of elevation from that half; ſubtract the verſed ſine of that difference from the verſed ſine of the angle made by the object and zenith: the difference of thoſe verſed ſines will be to the ſine of the angle laſt mentioned, as the horizontal diſtance of the object ſtruck to the greateſt range at forty-five degrees.

2. Having the greateſt horizontal range of a gun, the horizontal diſtance and angle of inclination of an object to the perpendicular, to find the two elevations neceſſary to ſtrike that object.—Take half the angle contained between the object and nadir, this half is equal to half the ſum of the two angles of elevation ſought; then ſay, as the horizontal range is to the horizontal diſtance of the object, ſo is the ſine of the angle of inclination to a fourth proportional; which fourth, being ſubtracted from the verſed ſine of the angle formed by the object and zenith, leaves the verſed ſine of half the difference of the angles of elevation, whoſe half ſum was before obtained; therefore, by adding and ſubtracting half the difference of the angles of elevation to and from the ſaid half ſum, the elevations themſelves will be found. See more under the article PROJECTILE.

HORIZONTAL REFRACTION. See the article REFRACTION.

HORIZONTAL SHELTERS, among gardeners, are defences diſpoſed parallel to the horizon, for tender plants, bloſſoms, and fruits, in the ſpring, to defend them againſt blaſts, and pinching nights.

Horizontal ſhelters, ſays Miller, have by ſome perſons been greatly recommended to perſerve fruit-trees, but with how little reaſon, or upon what ſlight experiments, every one that has ever made uſe of them will eaſily judge, eſpecially thoſe which are contrived by placing tiles in the walls, at certain diſtances; nothing being more obvious than that vegetables, when prevented from receiving the advantages of dews, rains, &c. theſe kindly benefits of heaven, grow weak, languid, and at laſt entirely decay: and from numbers of experiments, which have been lately made, we find that trees imbibe great quantities of nouriſhment through the pores of their leaves and branches, whereby they are rendered vigorous and healthy, even in ſuch ſeaſons, and upon ſuch ſoils, where one would think it impoſſible they ſhould receive much nouriſhment from the earth: to deprive them of this advantage, therefore, is no leſs than deſtroying them.

The only ſort of ſhelter Mr. Miller approves of, for fruit-trees, is that made with two leaves of ſlit-deal, joined over each other, and painted; theſe being fixed upon the top of the wall, with pullies, to draw up and down at pleaſure, form a ſort of penthouſe, which are let down in great rains, or cold nights, during the time that the trees are in flower, or the fruit is ſetting. But then, he obſerves, that theſe ſhelters ſhould be removed away ſoon after the fruit is ſet, ſo that the trees may enjoy all the advantages of rain, dew, &c. in the ſummer, which are abſolutely neceſſary to have healthy trees, or good fruit.

HORMINUM, clary, in botany. See CLARY.

HORN, *Cornu*, in phyſiology, a hard ſubſtance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and ſerving them both as weapons of offence and defence.

The caſting off the horns of deer is a ſingular phænomenon, the true reaſon of which ſeems to be a ſtoppage of the circulation; ſo that being deprived of the nouriſhing juice, they fall off much in the ſame manner as the leaves of trees do in autumn. About ten days after the horns are caſt, the new ones begin to appear: theſe at firſt are ſoft and hairy, but they afterwards grow hard, and the creature rubs off the hair.

HORN is alſo a muſical inſtrument of the wind kind, chiefly uſed in hunting, to animate the hunters and the dogs, and to call the latter together.

The French horn is bent into a circle, and goes two or three times round, growing gradually bigger and wider towards the end, which in ſome horns is nine or ten inches over.

HORN, in architecture, ſometimes denotes a volute. See VOLUTE.

HORNS *of Inſects*, the ſlender oblong bodies projected from the heads of thoſe animals, and otherwiſe called antennæ, or feelers.

HORN-WORK, in fortification, a ſort of out-work, advancing towards the field, to cover a curtain, baſtion, or other place ſuſpected to be weak, as alſo to poſſeſs an eminence, &c.

It conſiſts of two demi-baſtions joined by a curtain; its flanks are uſually parallel, though, ſometimes, they contract towards the place, forming a queue d'yronde, or ſwallow's tail. When the flanks are too long, ſometimes epaulements are made to flank them. The parts next the country are to be defended by a parapet. Two horn-works joined together make a crown-work.

HORNET, *Crabro*, in zoology, a ſpecies of apis with a black thorax, and double black ſpots on the ſegments of the body. See the article APIS.

HOROGRAPHY, the ſame with dialling. See the article DIAL.

HOROLOGIUM, a general name for inſtruments to meaſure the hours, as a watch, clock, dial, &c. See the articles WATCH, CLOCK, &c.

HOROPTER, in optics, a right line drawn through the point where the two optic axes meet, parallel to that which joins the centers of both the eyes; as the line A B (plate LXXIV. *fig.* 4.) which is drawn through the point of concourſe of the optic axes of the eyes D and E, parallel to H I, which connects the centers of the eyes H and I.

The word is Greek, and derived from ὁπτὴρ, beholder, which is formed of ὁπτομαι, to ſee, becauſe it is found by experience to be the limit of diſtinct viſion.

HOROSCOPE, in aſtrology, the point of the heavens riſing above the eaſtern point of the horizon, at any given time when a prediction is to be made of a future event; as the fortune of a perſon then born, the ſucceſs of a deſign, &c.

The word is Greek, and compounded of ὡρα, hour, and σκοπεω, to behold.

It alſo denotes a figure of the twelve houſes, or twelve ſigns of the zodiac, wherein the diſpoſition of the heavens is marked for the time given.

Lunar HOROSCOPE, the point from whence the moon proceeds when the ſun is in the aſcending point of the eaſt.

HORSE, *Equus*, in zoology, a well known quadruped, the characters of which are theſe: the fore-teeth

are ſix in number, the upper ones incurvated, and the inferior prominent: the canine teeth are not exerted, and are on each ſide ſeparated by a ſpace from the teeth: the hoof is undivided, and the teats are two, and placed in the groin.

The horſe is one of the nobleſt quadrupeds we are acquainted with. In ſtrength and natural fierceneſs, he is inferior to few, and yet eaſily tamed. The head is long, and large; the eyes large, and prominent; the ears erect, and beautiful; the neck is long and thick, and elegantly decorated with a mane; the body is rounded and beautifully turned; the legs are ſtrong, without being bulky; and the tail is long, and hairy all the way; the hairs being like thoſe of the mane, only longer, thicker, and more beautiful.

Though the moſt experienced horſemen are not always agreed in ſome points relating to the ſhape, make, and goings of a horſe, yet they almoſt always accord in this, that there ought to be a juſt proportion in all his parts. That even when he is taken to pieces, and examined ſingly in his particular members, though ſome defects may appear, yet when they all bear a juſt correſpondence one to another, and concur in ſuch a manner as to render his action eaſy, juſt, and regular; ſuch a horſe cannot be greatly diſagreeable, but will, for the moſt part, move well, and with a tolerable good grace. On the other hand, ſuppoſe a horſe has ſome parts exquiſitely fine, and others indifferent, which frequently happens, it will mar his beauty, and cauſe him to look diſagreeable, and for the moſt part affect his gait and action.

In order to have a horſe beautiful and finely made, it has been agreed on all hands, that his head ſhould not be long nor too large, rather lean than fleſhy. His ears thin and narrow, and of a becoming length, well ſet on, pointing inwards. His brow or forehead not too broad and flat. His noſe ſomewhat riſing, and of a good turn; his noſtrils wide and thin; his muzzle ſmall; his mouth neither deep nor too ſhallow, with a ſtar or ſnip down his forehead, or a blaze, which is no way unbecoming, unleſs it be too large and diſproportioned.

Horſes that are thus marked, have generally one or more of their feet white, which is alſo very beautiful, and looks lively. His jaws ſhould be thin and ſufficiently wide, not approaching too near together, nor too high upwards towards the onſet, that he may have ſufficient room to carry his head eaſy, and in good place. His eyes well formed, ſprightly, and of a middle ſize. His neck ſhould be arched towards the middle, ariſing by a beautiful gradation out of his breaſt and ſhoulders, the muſcles thereof diſtinct, but no where overcharged with fleſh, growing ſmaller and thinner, as it approaches towards his head. His ſhoulders ſhould be thin from the withers, with a gradual enlargement downwards, that his boſom or breaſt be not too narrow nor too groſs. His fore-legs ſtraight and well placed; his joints lean and bony; his knees not bending, and his paſterns not too long; his feet round and ſmooth, and his ſinews firm and well braced; his carcaſe rather round than flat; his back not too low, and for ſtrength and durableneſs pretty even and ſtraight. His ribs rather home than open, as they approach towards his haunches; his buttocks round, and the muſcles not too fleſhy but diſtinct; his hocks or gambrels neither ſtanding too wide, nor too near together; his hocks ſhould be lean and no ways puffed or fleſhy; his paſterns ſhort, his legs flat and thin, and his tail ſet on in a good place, rather high than low, riſing upon every motion of his body. The more theſe properties concur in any horſe, the more beautiful he muſt be, eſpecially when they correſpond and agree in due proportion, one to another; and the more a horſe is wanting in theſe, the more plain and ordinary he will appear.

A Deſcription of a HORSE-*Mill.*—Plate LXXII. *fig.* 2. exhibits the draught of a horſe-mill, compoſed of the great wheel A, which is ſuppoſed to contain one hundred and twelve cogs, which catch in the trundle-head B of ſeven wallowers. According to this diſpoſition, a horſe harneſſed at the bar C, making one turn, the mill-ſtone will make ſixteen.

In order to ſhew the beſt manner of building a mill, we muſt be determined by reaſon and experience concerning the proportion of its ſeveral parts.

The firſt point is to make the machine as ſimple as poſſible; yet it ſeems neceſſary to make a wheel and trundle-head, to give the mill-ſtone ſufficient velocity to turn round its axis forty times in a minute. The reſiſtance to be overcome muſt therefore be in proportion to the main ſtrength of a horſe, which is equal to one hundred and eighty pounds weight, at the end of a lever twelve feet long, when it acts in a horizontal direction, and the horſe goes about two thouſand fathoms an hour.

Let the radius of the wheel be eight feet, and one hundred and twelve cogs in the periphery, which catching in a trundle-head of ſeven wallowers, the mill-ſtone will make ſixteen turns for one of the wheel; and as the ſame proportion ought to be between the number of cogs and that of the wallowers, as of the radius of the wheel to that of the trundle-head, the radius of the trundle-head ought to be ſix inches.

As to the arm of the lever, at which the horſe is to be harneſſed, if it be too long, the horſe, having a large circumference to deſcribe, will make fewer turns in a minute, and the mill-houſe muſt be larger: it would therefore be proper to fix it at twelve feet, which is moſt convenient, in which caſe the horſe at every turn will deſcribe a circumference of twelve fathoms four-ſevenths; and as he can perform two thouſand of theſe in an hour, he will perform one hundred and ſixty turns in the ſame time, which, being multiplied by ſixteen, is equal to two thouſand five hundred and ſixty, the number of turns which the mill-ſtone makes in an hour at the rate of forty-two per minute.

HORSE-SHOE, in fortification, is a ſmall work ſometimes of a round and ſometimes of an oval figure, incloſed with a parapet, ſometimes raiſed in the moat or ditch, or in low grounds, and ſometimes to cover a gate, or to ſerve as a lodgment for ſoldiers.

HORSE-SHOE-HEAD, a diſeaſe in infants, in which the ſutures of the ſkull lie too open.

This is commonly a ſign of a weak conſtitution, and a ſhort life. The nurſes uſually embrocate the parts affected with brandy or rum, to which ſome add the white of an egg, or palm oil.

HORSE, in a military ſenſe, the ſame with cavalry. See the article CAVALRY.

The light horſe, in an army, are all the regiments of horſe, except the guards.

HORSE, among ſeamen, a rope faſtened to the yards in two places, for the men to tread on and ſecure themſelves by as they go out on the yard-arms to furl, reef, or looſen the ſails.

HORSE is alſo a rope drawn very tight perpendicularly cloſe to the maſt to hoiſt ſome ſail upon, as the try-ſail of a ſnow, the ſquare-ſail of a ſchooner, &c.

HORSE is likewiſe a name given by ſeamen to a ſhort reed thruſt into the bung of a caſk, or keg, to draw off brandy, gin, &c.

HORTICULTURE, the ſame with gardening. See GARDEN and GARDENING.

HORTUS SICCUS, a DRY-GARDEN, an appellation given to a collection of ſpecimens of plants carefully dried and preſerved.

HOSANNA, in the Hebrew ceremonies, a prayer which they rehearſed on the ſeveral days of their feaſt of tabernacles.

The word is Hebrew, and literally ſignifies, *ſave us now*, or, *ſave us we pray*.

HOSE, in commerce. See STOCKING.

HOSEA, a canonical book of the Old Teſtament, ſo called from the prophet of that name, its author, who was the ſon of Beri, and the firſt of the leſſer prophets. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jeroboam II. and his ſucceſſors, kings of Iſrael, and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal deſign is to publiſh the groſs idolatries of the people of Iſrael and Judah, to denounce the divine vengeance againſt them, and to foretel the captivity in Aſſyria.

HOSPITAL, a place or building properly endowed or otherwiſe ſupported by charitable contributions, for the reception and ſupport of the poor, aged, infirm, ſick or helpleſs.

Camp-HOSPITALS are either general or regimental. Th

The general hoſpitals are of two kinds, viz. the flying hoſpital, attending the camp at ſome convenient diſtance; and the ſtationary hoſpital, which is fixed at one place. In the choice of both Dr. Pringle thinks it better to have them in towns than villages, as the former will afford larger wards, beſides more of other conveniencies. Theſe wards ſhould be as airy as poſſible. Regimental hoſpitals are of the greateſt importance, and therefore ſhould be ſupplied with blankets and medicines from the public ſtores, with an allowance alſo for nurſes and other neceſſaries. Barns, ſtables, granaries, and other out-houſes, but above all churches, make the beſt hoſpitals from the beginning of June to October.

HOSPITAL-FEVER, a name given to the malignant catarrhal fever, as being frequent in hoſpitals. See the article MALIGNANT FEVER.

HOSPITALLERS, an order of religious knights, now known by the title of knights of Malta. See the article MALTA.

HOSPODAR, a title borne by the princes of Walachia and Moldavia, who receive the inveſtiture of their principalities from the grand ſeignior. He gives them a veſt and ſtandard: they are under his protection, and obliged to ſerve him, and he even ſometimes depoſes them; but in other reſpects they are abſolute ſovereigns within their own dominions.

HOST, *Hoſpes*, denotes either a perſon who entertains another, or the perſon ſo entertained; but it is now generally uſed in the firſt of theſe ſenſes.

HOST, or HOAST, *Hoſtia*, in the church of Rome, a name given to the elements uſed in the euchariſt, or rather to the conſecrated wafer; which they pretend to offer up every day, a new hoſt or ſacrifice, for the ſins of mankind.

HOSTAGE, a perſon given up to an enemy as a ſecurity for the performance of the articles of a treaty.

HOSTILITY denotes a ſtate of war or enmity between two nations.

During a truce all acts of hoſtility are to ceaſe on both ſides.

HOT-BATH. See the article BATH.

HOT-BEDS, in gardening, beds of earth enriched with manure, in order to forward vegetation, when the ſeaſon or climate is not warm enough for the purpoſe.

By means of hot-beds ſkilfully managed the ſeeds of plants brought from any country between the tropics, may be made to flouriſh even under the poles.

Heat and humidity being the great inſtruments of vegetation, to promote the growth of any plants, theſe muſt be duly proportioned, ſo as neither to exceed nor come ſhort of the bounds nature has allotted for it.

The uſual way of making hot-beds, is of horſe litter and graſs mixed together, and left on a heap for eight or ten days to putrefy; and then removed into a bed, and covered up with glaſſes.

For raiſing cauliflowers, cucumbers, melons, radiſhes, and other tender plants and flowers in January or February, Mortimer directs to provide a warm place defended from all the winds by being incloſed with a pale or hedge of reeds or ſtraw, about ſix or ſeven feet high. Within this raiſe a bed two or three feet high, and three feet over, of freſh horſe-dung, about ſeven or eight days old; then tread it down very hard, make it level, and, if you will, edge it round with boards or brick, laying fine rich mould about three or four inches thick on it. When you find by your finger, that the extreme heat of the bed is over, plant your ſeeds at pleaſure, and ſet your forks four or five inches above the bed, to ſupport the frame, and covered with ſtraw or mat to ſecure the ſeeds and plants from cold and wet; only uncover them in a warm day, an hour before noon, and cover them again an hour after. Obſerve to earth up your plants, as they ſhoot up, and when able to bear the cold, tranſplant them.

In Holland they uſe hot-beds made of ſand; and likewiſe of tanner's bark, which, when once rightly prepared, will maintain an equable heat for ſix months.

Bradley propoſes very juſtly a thermometer to be uſed to regulate the heat of the hot-beds. Thus a hot-bed for cucumbers muſt be kept ſo hot as to raiſe the ſpirit in a glaſs to the ſame height as the natural temperature of the weather will raiſe it to about the end of May and June, when cucumbers will grow without artificial heat or ſhelter.

HOT-HOUSE, in ſalt-making, the place where they dry the ſalt, when taken out of the boiling pan: it is ſituated near the furnace, which, by means of funnels or tubes, conveys the heat into it.

HOTCH-POT, in law, is uſed for mixing of lands given in marriage with other lands in fee which fall by deſcent; as where a man poſſeſſed of thirty acres of land has iſſue only two daughters, and after his having given with one of them ten acres in marriage, he dies poſſeſſed of the other twenty: here ſhe that is thus married, in order to gain her ſhare of the reſt of the land, muſt put her part given in marriage in hotch-pot; that is, ſhe muſt refuſe to take the ſole profits of her lands, and cauſe it to be mingled with the other, ſo that an equal diviſion may be made of the whole between her and her ſiſter; by which means, inſtead of only her ten acres, ſhe has fifteen.

HOTTS, or HUTTS, are the pounces and round balls of leather, ſtuffed, and tied to the ſpurs of fighting cocks, to keep them from hurting one another in ſparring.

HOUND, a hunting dog, of which there are ſeveral ſorts, as the grey-hound, gaze-hound, and the blood-hound.

HOUNDS *of the Maſt*, in the ſea-language, thoſe parts of the upper-end or head of a maſt upon which the cheeks are bolted to ſupport the truſſel-trees. See the articles MAST and TRUSSEL-TREES.

HOUR, *Hora*, a meaſure of time, ſome part of a natural day, uſually a twenty-fourth and twelfth, &c. With us it is equal to the twenty-fourth part of the earth's diurnal rotation. Each hour is divided into ſixty minutes, and each minute into ſixty ſeconds, &c. Fifteen degrees of the equator anſwer to an hour.

The word is derived from the Latin *hora*, which ſignifies the ſame thing.

The ancient Hebrews did not divide the day into hours, but into four parts, as morning, high-day or noon, midnight, and morning-watch. In the New Teſtament we find the day divided into twelve hours; but though they were equal to each other, yet they were unequal with reſpect to the different ſeaſons: thus the twelve hours of the longeſt day in ſummer were made longer than thoſe of the ſhorteſt days in winter. Herodotus ſays, that the Greeks learned from the Egyptians the method of dividing the day into twelve parts, the riſe of which cuſtom among the latter was, becauſe their prieſts were wont, twelve times a day, to cry aloud with a howling noiſe to their cynocephalus, and Cicero and Marius Victorinus have taken notice of ſuch a ceremony to Serapis.

Cenſorinus obſerves, that the word hour was not known among the Romans three hundred years after the building of the city, as there is no mention made of it in the twelve tables, as is done in the other laws after that time; before which, the diviſions were only before and after noon. The diviſion of the day and night into twenty-four hours was not known among them before the firſt Punic war. They divided the twelve hours of the day into four parts, as prime, which began at ſix o'clock; third, at nine; ſixth, at twelve; and ninth, at three. They alſo divided the night into four watches, each watch containing three hours.

The Turks not having any clocks, their prieſts, ſtopping their ears with their fingers, proclaim with a very loud voice from the top of their moſques, the cock-crow, break of day, noon-tide, three o'clock, and the twilight. The ſame cuſtom we find prevailed among the Romans, as appears from Martial;

Horas quinque, puer, nondum tibi nunciat.

The aſtronomers of Cathaya, &c. ſtill retain, according to biſhop Beveridge, the diviſion of the day into twelve parts, and give the name of ſome animal to each hour.

Hours are divided into equal and unequal; equal hours are the twenty-fourth part of a day and night preciſely, that is, the time wherein 15° of the equator mount above the horizon; they are alſo called equinoctial hours, as being meaſured on the equinoctial; and aſtronomical,

aſtronomical, becauſe uſed by aſtronomers, and reckoned from noon in a continued ſeries of twenty-four.

HOUSE, *Domus*, a habitation, or place built with conveniencies for dwelling in: thus we ſay, a town-houſe, country-houſe, &c.

HOUSE-BOTE, in law, an allowance of timber out of the lord's woods, for the repairs of a houſe: this is otherwiſe called eſtovers.

HOUSE, in aſtrology, denotes the twelfth part of the heavens.

HOUSE-BREAKING, or ROBBING, is the breaking into and robbing a houſe in the day-time, the ſame crime being termed burglary, when done by night; both are felony, without benefit of clergy.

Green-HOUSE. See the article GREEN-*Houſe*.

HOUSE-LEEK, ſedum, in botany. See the article SEDUM.

HOUSING, among bricklayers, a term uſed for a tile or brick that is warped, or caſt crooked or hollow in burning.

Tiles are apt to be houſing or hollow on the ſtruck ſide, or that which was uppermoſt in the mould, and bricks on the contrary ſide.

HOWKER, in the Dutch marine, a veſſel with two maſts, uſed in the coaſting trade.

HUCKSTER, a perſon who ſells proviſions, or ſmall ware, by retail.

HUE AND CRY, in law, the purſuit of a perſon who has committed felony on the highway.

If the party robbed, or any in the company of a perſon either robbed or murdered, go to the conſtable of the next town, and require him to raiſe hue and cry, and to purſue the offender, deſcribing him, and giving an account as near as he can, of the courſe he ſteered; the conſtable is immediately to call upon the pariſh for aid in ſeeking after the felon, and if he cannot be found within the bounds of that pariſh, then he is to give the next conſtable warning, and he the next, till the offender be apprehended, or at leaſt purſued to the ſea-ſide. If perſons are not ready at the ſummons of the ſheriff, and cry of the county, to engage in the purſuit, they may be fined: and in caſe the inhabitants of any hundred, after hue and cry is made, neglect to purſue the ſame, they ſhall be liable to pay one half of the damages recoverable againſt the hundred in which the robbery was committed.

HUGUENOTS, a name given by way of contempt to the Calviniſts of France.

The name had its riſe in the year 1560; but authors are not agreed as to its origin. The moſt plauſible opinion, however, is that of Paſquier, who obſerves, that at Tours, the place where they were firſt thus denominated, the people had a notion, that an apparition or hobgoblin, called king Hugon, ſtrolled about the ſtreets in the night-time; from whence, as thoſe of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots; that is, the diſciples of king Hugon.

HULK, in the marine, an old ſhip of war properly fitted with a very high maſt, firmly ſupported by various props and ſhrouds to hoiſt in and out the maſts of other men of war occaſionally; alſo an old ſhip of any kind.

HULL, in ſhip-building, the hull or lower-frame of a ſhip excluſive of the ſuperſtructure, viz. the maſts, ſails, and rigging.

HULL-TO, the ſituation of a ſhip lying-to at ſea, without any ſail ſet. See the article TRYING.

HUMAN, in general, is an appellation given to whatever relates to mankind: thus we ſay, the human ſoul, human body, human laws, &c. See the articles SOUL and BODY.

HUMANITY, the peculiar nature of man, whereby he is diſtinguiſhed from all other beings. See the article MAN.

HUMANITIES, in the plural, ſignify grammar, rhetoric, and poetry, known by the name of *literæ humaniores*; for teaching of which, there are profeſſors in the univerſities of Scotland, called humaniſts. See GRAMMAR, RHETORIC, &c.

HUMBLE-BEE, the Engliſh name of ſeveral ſpecies of apis, diſtinguiſhed by their colours, black, tawny, reddiſh, &c. See the article APIS.

HUMECTATION, in pharmacy, the moiſtening or preparing medicines by ſteeping them in water; either to ſoften and relax their ſolid parts, or to prevent the evaporation of their more ſubtile contents.

HUMERUS, in anatomy, the upper part of the arm between the ſcapula and elbow.

The os humeri or brachii, as it is called, is articulated at one end with the ſcapula, and at the other to the ulna and radius. See the articles ARM, BRACHIUM, &c.

As to the motion of the os humeri, it is evidently the moſt free and extenſive of that of any bone in the human body; being furniſhed with ſeveral flexor and extenſor muſcles. See FLEXOR and EXTENSOR.

HUMIDITY, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity, and ſeems to be merely a relative thing depending upon the congruity of the component particles of the liquor to the pores of ſuch particular bodies, as it is capable of adhering to, penetrating a little into, or wetting.

HUMIDUM RADICALE, or *Radical Moiſture*, among phyſicians, ſeems to amount to no more than the pureſt and moſt delicate part of the nutritious matter in a condition to be aſſimilated.

By too much heat, as in fevers, hectics, &c. this humidity is too haſtily exhauſted and ſpent.

HUMILIS MUSCULUS, one of the depreſſor-muſcles of the eye.

HUMMING-BIRD, *Trochilus*, in ornithology, a genus of birds, of the order of the paſſeres, remarkable for being the ſmalleſt of all known birds. Their beak is of a ſubulated figure, but fine as a thread: it is longer than the head, and not perfectly ſtraight: add to this, that they have a fine tube or pipe, which they can extend beyond the point of the beak. Of this ſingular genus, there are ſeveral elegant ſpecies.

HUMORISTS, *Gli Humoriſti*, a celebrated academy of learned men at Rome, firſt eſtabliſhed by Paul Mancini. The device of this academy is a cloud; which being raiſed on vapours from the ſalt water of the ſea, returns again freſh, with this hemiſtich from Lucretius, *Redit agmine dulci*.

HUMOROSI, the name of another academy at Cortona in Italy, which muſt not be confounded with that of the Humoriſts.

HUMOUR, *Humor*, in a general ſenſe, denotes much the ſame with liquid or fluid. See the article FLUID.

The ancients ſeem to have called the nutritious juices the radical humour; and to have conſtituted as a cauſe of diſeaſes, a diſproportion betwixt the innate heat and radical moiſture or humour. They alſo made four humours in the blood. See the article BLOOD.

HUMOURS *of the Eye*, are the cryſtalline, vitreous, and aqueous; for a deſcription of which, ſee the articles EYE, CRYSTALLINE, &c.

HUMOUR is alſo uſed for the peculiar temper of a perſon, ariſing from the conſtitution and prevalence of this or that humour. See the articles CONSTITUTION and TEMPERAMENT.

HUMOUR, in dramatic poetry, is eſteemed a ſubordinate ſpecies of what is more uſually called manners. See MANNERS.

Every paſſion wears two different faces; one ſerious and ſolemn, fit only for tragedy; and the other merry and ridiculous, called humour, and proper for comedy. The Engliſh poets have excelled thoſe of all other nations in this particular; and, indeed, ours is the only language that has a name for it.

To be always witty only becomes a few characters; ſo that it is neceſſary to call in the aſſiſtance of humour, to prevent the other dramatic perſons from going into the common ſtyle and manner: hence humour may be looked on as the true ſpirit and wit of comedy. See the article WIT.

HUMULUS, the hop, in botany. See the article HOP.

HUNDRED, *Centum*, *Cent*, is ten times ten, or the ſquare of ten. It makes the third place from the right to the left in the table of numeration.

The

The proportion of the profits in commerce is reckoned by the hundred, or ſo much per cent.

HUNDRED, *Hundredum*, *Centuria*, a certain diviſion or part of a ſhire or county.

HUNGARICUS MORBUS, a diſeaſe ſo called from its being firſt obſerved in the imperial army, in 1556.

It is thought to have been a compound fever, partaking of the nature both of the bilious and malignant fevers. See BILIOUS and MALIGNANT-FEVER.

HUNGARY, a kingdom bounded by the Carpathian mountains, which divide it from Poland, on the north; by Tanſilvania and Walachia on the eaſt; by the river Drave, which ſeparates it from Sclavonia, on the ſouth; and by Auſtria and Moravia on the weſt. It is one continued plain of 300 miles long, and is ſituated between 16° and 23° of eaſt lon. and between 45° and 49° of north lat.

HUNGARY-WATER, a diſtilled water, ſo denominated from a queen of Hungary, for whoſe uſe it was firſt prepared.

Quincy gives the following directions for making it. Take of freſh gathered flowers of roſemary, two pounds; rectified ſpirits of wine, two quarts; put them together, and diſtil them immediately in balneo.

Or, Take of freſh tops of roſemary, one pound and a half; proof ſpirit, one gallon; and diſtil in balneo till five pints are obtained.

HUNGER, an uneaſy ſenſation, which creates an appetite or deſire of food. See the article FOOD.

Hunger is by ſome attributed to a ſharp acrimonious humour, which vellicates the coats of the ſtomach; others, who deny the exiſtence of any ſuch liquor, attribute it to the attrition or rubbing of the coats of the ſtomach; and others, again, account for it from the acidity of the blood.

HUNGRY EVIL, among farriers, an exceſſive deſire in horſes to eat, which ſometimes proceeds from catching cold, or from travelling long in froſt and ſnow, or through barren places.

For the cure, give him great ſlices of bread, toaſted and ſteeped in ſack, to comfort his ſtomach; or give him wheat flour in wine or milk, a quart at a time. But there is nothing better than to feed him moderately ſeveral times a day with good bean-bread well baked, or with oats well dried and ſifted.

HUNTING, the exerciſe or diverſion of purſuing four-footed beaſts of game. See the article GAME.

HUOY, a veſſel uſed to load and unload large ſhips, either in the king's or merchants ſervice; alſo a ſmall Dutch ſhip with a main-maſt and mizen maſt.

HURA, the ſand-box tree, in botany, a genus of plants, the male flowers of which are arranged in an imbricated amentum; the antheræ are ſeſſile, and adhere to the amentum; the female flower has neither calyx nor corolla; its ſtyle is funnel-ſhaped, and the fruit is a capſule conſiſting of twelve cells, in each of which is contained a ſingle ſeed.

HURDLES, in fortification, twigs of willows or oſiers interwoven cloſe together, ſuſtained by long ſtakes, and uſually laden with earth.

Hurdles, called alſo clays, are made in the figure of a long ſquare; the length being five or ſix feet, and the breadth three, or three and an half: the cloſer they are woven, the better. They ſerve to render batteries firm, or to conſolidate the paſſage over muddy ditches; or to cover traverſes and lodgments, for the defence of the workmen, againſt the fire-works, or the ſtones that may be thrown againſt them.

HURDLES, in huſbandry, certain frames, made either of ſplit timber, or of hazel-rods, wattled together, to ſerve for gates in incloſures, or to make ſheep-folds, &c.

HURDS, or HORDS, *of Flax*, or *Hemp*, the coarſer parts ſeparated in the dreſſings, from the tear or fine ſtuff.

HURLE-BONE, in a horſe, a bone near the middle of the buttock, very apt to go out of its ſockets with a hurt or ſtrain.

HURRICANE, a furious ſtorm of wind, owing to a contrariety of winds. See the articles WIND and WHIRLWIND.

HUSBAND, *Maritus*, a man joined or contracted with a woman in marriage.

HUSBANDRY, the buſineſs or employment of a farmer, or perſon who cultivates land, &c. See AGRICULTURE.

Huſbandry is divided into two kinds, and diſtinguiſhed by the epithets old and new. The former is that which has been practiſed in all countries from the moſt early times; and the latter that introduced by the ingenious Mr. Tull, and often called the horſe-hoeing huſbandry.

Experience ſhews, that land, though ever ſo well tilled in the autumn, when wheat for example, is ſown, hardens and ſaddens in the winter; its particles, beaten down by heavy rains, and ſunk by their own weight, approach each other daily more and more; the roots of the plants cultivated have conſequently leſs and leſs room to extend themſelves in queſt of their neceſſary food; and the interſtices in the earth become of courſe ſo few and cloſe, that they are not able to pierce through them; whilſt weeds ſpring up, and rob them of their nouriſhment. By this means the earth, reduced to nearly the ſame condition as if it had not been ploughed at all, is unable to aſſiſt the plants ſown in it, in the ſpring, when they ought to ſhoot with the greateſt vigour. They conſequently then ſtand moſt of all in need of the plough, to deſtroy the weeds, to lay freſh earth to their roots in the room of that which they have exhauſted, to break the particles of the ground a-new, ſo as to enable their roots to ſpread, in order to their gathering an ample proviſion of food, which then does them the greateſt ſervice.

In the common huſbandry, the whole attention is to provide a great ſtore of nouriſhment for the wheat at a time when it ſcarcely conſumes any, as it then produces only a few blades; after which it is left to itſelf, at a ſeaſon when it might, and ſhould, be moſt aſſiſted by proper culture: a management as prepoſterous, as it would be to give a child a great deal of food, and diminiſh it gradually as he grows bigger; or, to uſe Mr. Tull's compariſon, to give ſilk-worms, before they are hatched, treble the full ſtock of leaves neceſſary to maintain them till they have finiſhed their ſpinning, and not to allow them any when they really want being fed.

The great advantage of having land in fine tilth before it is ſowed, is univerſally acknowledged: but we muſt not ſtop at thoſe firſt preparations. Plants require a continuation of culture while they grow, and muſt not be forſaken till they have attained their full maturity.

Thoſe who are againſt the frequent ploughings uſed in the new huſbandry, are afraid of drying the earth too much; becauſe, ſay they, the moiſture eſcapes more eaſily from a well looſened ſoil, than from a hard and cloſe earth.

In anſwer to this it will appear from many of the following experiments, that, even in the drieſt weather, land cultivated according to the new method, continues conſtantly moiſter than that which is managed in the old way. Inſtead of a ſtagnant wet, more hurtful, perhaps, than beneficial, to plants; earth made fine to a good depth, is prepared, as the reverend Dr. Eliot expreſſes it, "with open mouth, to drink and retain the dew, which, when it falls upon the land that is untilled, or but poorly tilled, does not ſink far, but is carried off by the next ſun's heat." That dew is one of the greateſt fertilizers of the earth, has been repeatedly proved; and that it will penetrate ſo deep in a fine looſe ſoil, as to keep that moiſt, while the ground around it is parched up, appears, among many demonſtrations, from Mr. Evelyn's experiment of digging a hole, and filling it up with its former mould well pulverized: or, as Mr. Tull obſerves, till a field in lands; make one land very fine by frequent deep ploughings, and let another be rough, by inſufficient tillage, alternately: then plough the whole field croſs wiſe in the drieſt weather, which has continued long; and you will perceive, by the colour of the earth, that every fine land will be turned up moiſt; but every rough land will be dry as powder, from top to bottom.

Another proof of the benefits which ariſe from ſtirring the ground well and often between plants, while they grow, and conſequently a confirmation of the fundamental principle of the horſe-hoeing huſbandry, is thus drawn

by Dr. Eliot, from the common manner of raiſing Indian corn.

"The land, ſays he, being previouſly prepared, planted, and the corn come up, we plough a furrow off from the corn on each ſide, then hoe it, and the next time plough up to the corn; ſo that this tillage is nearly the ſame as is now propoſed for wheat, or whatever we would plant: only by the way, I would obſerve, that the ploughings between the rows, for Indian corn, is ſo ſhallow, that one would be apt to think it intended for nothing more than merely to kill the graſs and weeds; whereas it is found by experience, that, though there be neither graſs nor weeds, the ploughing and hoeing will make the corn grow, and that the more the land is ploughed and hoed, the better and longer it will reſiſt drought, and yield the better crop: nay, what is ſtill more remarkable, if the Indian corn be well tilled, the next crop, whether it be oats or flax, will be proportionably greater and better; ſo that the land muſt have gained ſtrength and richneſs. If it were not ſo, why did not the Indian crop exhauſt and ſpend the ſtrength of the land, eſpecially when we conſider how large that corn is made to grow by good tillage? But we find the contrary; the better the crop of Indian corn, the better the crop will be of oats. There is no ſort of huſbandry, wherein the ſuperior force and virtue of tillage doth ſo evidently appear, as in the raiſing of Indian corn: for if you ſhould plough and harrow the beſt of land, and ſow or plant the corn, and never do any thing more to it, there will be leſs corn than if you ſhould plant poor land, and tend it well: the poor land well ploughed and hoed, ſhall bring a greater crop than the rich land. We hereby ſee the efficacy and advantage of this repeated tillage, which falls in ſucceſſively, according to the exigency and want of the plant in its ſeveral degrees of growth, and keeps the land in a proper ſtate. Why ſhould it not have the ſame effect upon wheat, and every other plant that is ſuſceptible of the like culture?"

If ſeveral rows of wheat are ſown in a poor but well ploughed land, the blades of the corn will turn yellow in the ſpring, eſpecially in dry weather. Let the earth bordering upon theſe rows be ploughed deep, in ſome places near, and in others farther from the rows, and the plants will reſume their proper colour; firſt in the places neareſt to the new ploughed ground, and afterwards gradually in the others, according to their diſtance; which proves that they recover their verdure, in proportion as their roots reach the looſe mould. This holds equally true in all plants; for Mr. Tull declares, that he does not remember ever to have ſeen a poor one contiguous to a well-hoed interval, unleſs overpowered by a too great multitude of other plants, an exception which muſt be equally made if it were a plant that required more or leſs heat or moiſture than the ſoil or climate afforded; and that, on the contrary, he has ſeen plants grow to an amazing ſize, when the earth around them has been frequently tilled. He mentions, among others, a plant of ray-graſs, which chanced to ſtand in a turnip field, where, being hoed as the turnips were, it acquired a bulk at leaſt equal to a thouſand plants of the ſame ſpecies; and a plant of muſtard, which grew higher than he could reach, ſo as to be more like a tree than an herb.

The ſtirring of the earth about the plants whilſt they grow, is productive of ſuch excellent effects, that, in ſome parts of Berkſhire, and in many places in France, they hand-hoe their corn, particularly wheat, and find that the crops amply repay all the charge and trouble of this expenſive operation; which, however, cannot be performed but in well-peopled countries. Every huſbandman will immediately ſee, how much a hoe-plough is preferable for this work, and that, to uſe it rightly, the corn muſt neceſſarily be planted in regular rows, as it is in the new huſbandry.

Our reaſon tells us, that the longeſt lived plants ſtand moſt in need of this culture. Perennials require it more than annuals, and wheat which is ſown in autumn, and does not ripen till nine months after, wants it more than ſpring-corn, which occupies the ground only for a few months. The former has to conquer a ſoil rendered hard during the courſe of the winter; but the other has not that difficulty to ſurmount, though both of them, and indeed all ſorts of plants, are greatly invigorated by the repeated laying of fine freſh earth to their roots. Every one knows the vaſt efficacy of wood land, before its native ſtrength and vigour are exhauſted; and ſuch, in ſome degree, is that which this tillage furniſhes; beſides being conſtantly attended with the advantage of deſtroying weeds. How far this laſt important part of agriculture was well executed by the farcling, or ſarriſon, as Mr. Tull calls it, of the ancients, I ſhall not pretend to ſay, becauſe we have no clear account of the manner in which it was performed; but it does not ſeem to have been in any way equal to the horſe-hoeing huſbandry, which likewiſe, among its many other excellencies, keeps the land from going out of tilth.

We ſhall here add Mr. Duhamel's obſervations on the uſe of dung, as given by that gentleman in his *Elements of Agriculture*.

"It is often, ſays he, more advantageous to increaſe the fertility of land by ploughing, than by dung: 1. Becauſe, in general, only a certain quantity of dung can be had, the product of twenty acres being ſcarcely ſufficient to produce enough for four or five; whereas the particles of the earth may be divided and ſubdivided almoſt to infinity. The help derived from dung is therefore limited; whilſt no bounds can be ſet to the benefits that may accrue from ploughing.

"2. Few plants raiſed in dung ever have the fine flavour of thoſe which grow in a good ſoil moderately dunged. Our kitchen gardens and our other grounds afford daily inſtances of this truth. Pulſe, pot-herbs, and fruit, are ſeldom ſo good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is uſed. The corn raiſed in thoſe exceſſively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horſes will not eat oats of the growth of fields manured with human ordure. But nothing is ſo ſtriking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

"3. Dung, which is ſuppoſed to act by fermentation, cauſes indeed an inward diviſion of the particles of the earth, which muſt be very uſeful, as well as the food which it furniſhes to plants: but the plough, beſides dividing thoſe particles, changes their ſituation, and turns the ground upſide down, ſo that the part which was expoſed to the influences of the air and dews, takes the place of another part which is brought from within the earth, up to its ſurface. The conſequence of this is, that well ploughed land is not exhauſted by weeds, and that it admits the moiſture of rains and dews, together with the rays of the ſun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

"4. Dung attracts inſects, and thoſe inſects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by inſects: and this is one of the chief reaſons why florifts baniſh dung from their gardens. Worms, grubs, and other ſuch like vermin, make dreadful havock in their beds of flowers; and I have ſeen meadows where the graſs has been entirely deſtroyed, by their eating its roots.

"I muſt add, that moſt ſorts of dung contain a great many ſeeds which fill the land with weeds.

"5. It is true that dung is equally ſerviceable to light lands, and to ſtrong; but the ſame may be ſaid of ploughing.

"Land is too ſtrong when its particles lie ſo cloſe together, that the roots of plants cannot extend between them, without great difficulty, in queſt of their neceſſary food; for want of which they will remain poor and ſickly: but when the ground has been well looſened by repeated ploughings, and its plants are ſet at greater diſtances from each other, thoſe roots will be able to ſpread freely on all ſides, to pervade every minute chaſm, and to collect ſuch quantities of food as will make the plants grow ſtrong and vigorous. The friendly influences of the atmoſphere will then penetrate to them. What plainly proves the good effects of looſening ſuch ſoils, is, that their fertility is ſometimes increaſed by a mixture of ſand, inſtead of dung

dung. Now ſand does not afford any nutritive ſubſtance; but only hinders the particles of the earth from re uniting too cloſely.

"Ploughing is equally beneficial to light lands, for the very contrary reaſon; though theſe do not require ſo much of it as the other. There is no danger of their being exhauſted by any expoſure to the ſun; but, on the contrary, they acquire an additional degree of fertility by the ſtirring and grinding of their particles, and are thereby the better fitted to receive the moiſture of rains and dews, and the ſalutary influences of the air and ſun; whilſt their inward pores are at the ſame time better adapted to the proper extenſions of the roots of plants, by their being leſſened.

"But, let the benefits ariſing from dung be ever ſo great, let the means of obtaining enough of it be ever ſo eaſy, and let even its defects be corrected as much as can be, ſtill it will not be the leſs true, that frequent ploughing is of infinite ſervice to land.

"For this reaſon it is, that land intended for wheat is ploughed three or four times before the grain is ſowed. Some farmers, who could not dung all their lands, ploughed part of them double the uſual number of times, and reaped greater crops from theſe, than from thoſe which were dunged. The expence of the ploughings extraordinary will be much leſs than the price of the dung neceſſary for the land, if the farmer is obliged to purchaſe it.

"In 1759, M. Delu gave three ploughings to ſome of his fields intended for oats; and though that year was very dry and unfavourable to ſpring corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

"He gave five ploughings to a piece of wheat-land, which had not been dunged, and at harveſt, had taller and finer corn there, than in the neighbouring grounds which had been dunged and cultivated in the uſual way. In ſhort, the advantage of thorough tillage, while the plants are growing, is ſo great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn.

"The farmer muſt not think of practiſing the new huſbandry in land which cannot be brought to a fine tilth: for as no remedies are proper for all diſeaſes, ſo no one culture can ſuit every kind of ſoil.

"I have met with very zealous huſbandmen, who have been in a great hurry to procure all the inſtruments proper for the horſe-hoeing huſbandry, before they had examined whether their ground was fit for uſing them. In walking over the fields, I have found them in ſo bad order as to be full of clods, ſtones, and all ſorts of weeds: only the bare ſurface of the land had been ſcratched, by what they called ploughing; and indeed their common inſtruments of tillage were ſo imperfect, that it was hardly poſſible for them to do more. I adviſed them to deſtroy thoſe weeds by good and frequent ploughing, to procure good inſtruments, to looſen the ground to a proper depth, to collect good manures, to drain their land well by trenches and ditches, and, in ſhort, to practiſe the old huſbandry completely, before they attempted the new; for, in fact, all the requiſites in the former muſt be the foundation of the latter.

"To anſwer the ends of this husbandry, the ſeeds muſt be diſtributed ſo ſparingly, that each plant may have room to extend its roots in ſuch manner that they may be able to collect an abundant quantity of food; each plant muſt be enabled to tiller greatly, ſo as to produce a conſiderable number of ſtalks; and each ſtalk muſt be enabled to bear a fine long ear, well filled with grains to its very point.

"To effect the firſt of theſe qualities, the field, after being thoroughly ploughed and well harrowed, muſt be divided by furrows, the ſpaces between which may be of ſuch breadth as ſhall be judged moſt proper; for neither their preciſe width, nor the diſtance between the rows of corn, is yet fully determined. In the middle of theſe ſpaces, which will be diſtinguiſhed by the name of beds, the wheat, or other grain, is to be ſown in one, two, or more rows. An inch will be ſufficient for the diſtance between the grains, length-wiſe of the row; though that may be ſomewhat leſs, if the ground be not very good for wheat; or, on the contrary, ſomewhat more if it be excellent for that grain. By this diſtribution, each plant will find, in the intermediate ſpaces between the beds, and in the beds themſelves, a ſufficient extent of earth wherein to collect its neceſſary food; for thoſe intermediate ſpaces, which I ſhall call alleys, muſt be wide enough to admit of ſtirring the ground in them while the plants grow: but, to anſwer the ſecond and third intentions, it is of conſequence that theſe ſtirrings be performed at proper ſeaſons, becauſe each of them is to produce its particular effect.

"It is eſſentially neceſſary that the rows of corn be ſown very ſtraight; a circumſtance which, though it be attended with ſome trouble, ought not to diſcourage the huſbandman, becauſe the great difficulty will be only the firſt time. After the ground has been once rightly ſown, it will be eaſy to continue in the ſame regular track every following year, without taking the precautions I am now going to obſerve.

"If the field be not very large, a furrow traced with a ſpade or pick-ax, directed by a line ſtretched acroſs the ground, will enable the ploughman to guide the horſe that draws the drill; and he will take care to leave a proper interval between one furrow and another, if three rows are to be ſown.

"If the extent of ground be too great for the above method, poles or ſtakes may be ſtuck, five feet aſunder, at each end of the field, to guide the ploughman, who, with a common plough, will trace ſmall furrows, by the help of which the horſe and drill may be properly directed.

"It will be right, if poſſible, to ſuit the direction of the furrows to the declivity of the land, that the water may drain down to the loweſt part of the field, where a ditch ſhould be dug to carry it off: and it will alſo be neceſſary, to make them lengthwiſe of the field, if convenient, that the leſs ground may be loſt by the ſpace which muſt be left for the plough to turn in.

"After the ſeed is put into the hoppers of the drill, the horſe which draws this inſtrument muſt be made to walk ſlowly in the furrow before traced by way of guide: and in order to drop as nearly as poſſible the intended quantity of ſeed, the outlet of the hopper muſt be proportioned to the ſize of the grain.

"As it will be ſomewhat difficult to manage the drill rightly at firſt, till the husbandman becomes uſed to it; he ſhould look over his field as ſoon as the corn has ſprouted, and then drop by hand a few grains in the places where it may have failed.

"The land ſhould be ſown about the middle of September, or, at fartheſt, by the end of that month: and it will be right always to try the goodneſs of the ſeed before-hand, by ſowing fifty or an hundred grains of it in a fine mould, or moiſt ground, where it will ſoon appear whether they all riſe.

"Land which retains water ſhould be ploughed once in October, when the weather is fine. In doing this, a furrow ſhould be firſt cut in the middle of the alleys, and then it ſhould be filled with the earth on each ſide, even ſo far as to arch it up, and leave only a ſmall furrow on either ſide, cloſe to the beds, to drain off the wet, which would prove very prejudicial to the plants if it were to remain long near their roots. This looſening of the earth will alſo fit it for being mellowed by the winter's froſts; to which, however, care muſt be taken not to expoſe the roots of the corn, by leaving them too bare of mould. The moſt proper time for this ſtirring of the ground is when the plants have ſhot out ſome blades.

"The ſecond horſe-hoeing, which ſhould be given as ſoon as the hard froſts are paſt, that is to ſay, by the end of March, is intended to make the plants tiller; and will have this effect, if, after the earth near the rows has been ſtirred a little, that which was before laid up in the middle of the alleys be returned back to the furrows at their ſides. This earth, having been mellowed during the winter, will afford excellent nouriſhment to the plants now beginning to vegetate apace, and they will ſoon put forth their multiplied ſtalks.

"The third hoeing, which is the ſecond after winter, and is intended to ſtrengthen the ſtalks, ſhould be performed when the ears of the corn begin to appear. This culture, which is looked upon as the leaſt important of

all, and is ſometimes even omitted without any great inconvenience, need not be any thing more than a ſlight ſtirring of the earth, in which it will, however, be right to begin to hollow the alleys.

" The laſt ſtirring of the earth between the rows of corn is one of the moſt important; being that which makes the grains ſwell, and grow full bodied to the very point of the ear. The moſt proper time for this is when the ears begin to bloom: but as the corn is then high, only one furrow can be cut in the middle of the alleys, the earth of which ſhould be laid up to the ſtems of the plants on each ſide. The plough will hardly be able to paſs more than twice in this furrow, which ſhould, however, be made as deep as poſſible, in order to bank up the greater quantity of earth. By this operation, the now fallow alleys are prepared for the next ſowing, for it is in the middle of them that the corn is to be planted the following year; and the now eared wheat is earthed up, to prevent its being lodged; though in general, corn thus cultivated is leſs apt to be beaten down, than that which is raiſed in the common way, becauſe the ſtraw of this, being more expoſed to the air, becomes harder, and acquires a firmer texture, eſpecially toward its bottom. It is for this reaſon that a tuft of corn, which ſtands quite ſingle, is ſcarcely ever beaten down by the weather.

" Theſe repeated hoeings of the earth will certainly be rewarded with a very plentiful crop, unleſs the ſeaſons prove extremely bad.

" When the corn is reaped, all poſſible care ſhould be taken not to trample upon the adjoining ploughed ground.

" It is well known, that vigorous plants do not ripen their ſeeds ſo ſoon as thoſe which have been ſtinted in their growth: for this reaſon, the corn cultivated according to the principles of the new husbandry, ripens later than in the common way, and ſhould therefore be ſown ſomewhat earlier.

" We will now ſuppoſe that the crop is reaped, and that the ſame field is to be ſown again with wheat the next year, and every year after, as it may be; becauſe the rows of corn are placed each time in the middle of the former alleys, which have been ploughed during the whole year without producing any thing. Thus, the only difference between this new method and the old husbandry is, that inſtead of reſting, or fallowing, a whole field, whilſt another whole field is under corn, and each of them is ſeparate from the other; the fallow here is in the ſame field as the corn; being interpoſed by means of alleys, which are the part reſted, between the beds, which are the part cultivated: but there is this great advantage here, that the ſtirring of the earth in the alleys, which are not planted, not only prepares the ſoil admirably for being ſown the next year, but invigorates the plants actually growing in the beds.

" If it be thought proper to dung the alleys, in order to prepare them for the reception of the ſeed, the dung, which ſhould be thoroughly rotten, muſt be laid in the bottom of the deep furrow before made in the middle of them, and there covered with the earth which was thrown up towards the rows of wheat. If the land does not want dunging, this deep furrow is filled up without it; and this ſhould be done immediately after harveſt, that there may be time to give the ground another ſtirring, which need only be a ſlight one, before the ſowing of the rows, which are now to be in the middle of the former alleys; and the alleys of this year will be in the place of the laſt year's ſtubble.

" Though land, cultivated according to the principles of the new husbandry, does not require ſo much dunging as that which is managed in the old way, yet this manure will always help to enrich the ſoil, eſpecially if it be uſed by the manner here directed. By being thoroughly rotten when it is laid in the furrow, and there covered over immediately after harveſt, it will have time to mellow and diffuſe its influence, and not be apt afterwards to choak up the ſhares of the drill: an inconvenience which does not happen with pigeon's dung, which therefore need not be ſtrewed till the ground is ploughed for ſowing."

" It is farther obſerved:

" 1. That if dung be uſed for the ſecond year's crop, very little of it will ſuffice; becauſe it need only be laid in the bottom of the furrows.

" 2. That there can hardly be any occaſion for dung this ſecond year, becauſe, if the earth of the beds in which the wheat grew was good, that of the alleys, of the ſame ſoil, muſt be ſtill better by reaſon of its having been fallowed and well tilled.

" 3. That the ſecond year's wheat is placed in a moſt advantageous ſituation, its roots having a depth of twelve or fifteen inches to extend themſelves in, by means of the furrow which was in the middle of the alley. For this reaſon, corn ought to thrive beſt in thoſe lands which have been longeſt cultivated according to the new huſbandry.

" The earth in the alleys is to be horſe-hoed during the ſecond year, in the ſame manner, and at the ſame ſeaſons, as in the firſt.

" This frequency of hoeing ought not to be objected to; for the labour of the firſt hoeing, to make the furrows on each ſide of the rows, and lay the earth up in the middle of the alleys, cannot be great; and the ſecond only returns that earth into thoſe furrows: the third is only to ſtir the ſurface of the ſoil: the fourth and laſt is to make the deep furrow in the middle of the alleys, and bank up the rows of corn on each ſide, with the earth taken out of it: ſo that neither of theſe operations ever extends to above a third part of the ground, at any one time.

" The whole field might indeed be ploughed up after harveſt: but I would adviſe the husbandman not to touch the ſtubble then, becauſe the rows of that will help him to guide the drill in ſtraight lines, and the yet un-rotten ſtraw might be apt to clog the ſhares of the drill, ſo as to prevent their working properly. However, if the ſtubble be very ſhort, this caution becomes the leſs material, and the whole field may then be ploughed: though ſtill it will be neceſſary to plough it again in October, in order to make drains to carry off the wet.

" It is almoſt needleſs to obſerve, that all the operations of which I have been ſpeaking, muſt often be performed either a little earlier, or ſomewhat later, according as the year is more or leſs forward; and that it will always be neceſſary to wait till the ground is dry enough to be ploughed without danger of its clodding; a circumſtance which varies greatly, according to the nature of the ſoil." *Mills's Huſbandry.*

The editors of the laſt edition of Mr. Tull's Horſe-Hoeing Husbandry give, in their preface to that work, the following comparative calculation of the expence and profit of the old method of culture and the new, drawn up by a gentleman who has practiſed both for ſome years, and who has no attachment to the new husbandry, farther than he has found it anſwer in his trials. They candidly appeal to experience, " whether every article in this calculation is not eſtimated in favour of the common husbandry; whether the expence be not rated lower than moſt farmers find it; and whether the crop be not ſuch as they would rejoice to ſee, but ſeldom do.

" In the new huſbandry, every article is put at its full value, and the crop of each year is computed four buſhels ſhort of the other; though, in ſeveral years experience, it has equalled, and generally exceeded, thoſe of the neighbourhood in the old way."

An Eſtimate of the Expence and Profit of Ten Acres of Land, in Twenty Years.

I. In the Old Way.

	l.	s.	d.	l.	s.	d.
Firſt year for wheat coſts 33l. 5s. viz.						
Firſt ploughing at 6 s. per acre —	3	0	0			
Second and third ditto, at 8s. per acre	4	0	0			
Manure, 30 s. per acre — — —	15	0	0	22	0	0
Two harrowings and ſowings, at 2 s. 6 d. per acre — — — —	1	5	0			
Seed, three buſhels per acre, at 4 s. per buſhel — — — — —	6	0	0			
Weeding, at 2 s. per acre — —	1	0	0			
Reaping, binding, and carrying in, at 6 s. per acre — — — —	3	0	0	11	5	0
Carried forward — —				33	5	0

			l.	s.	d.
Brought forward	—	—	33	0	5
Second year for barley coſts 11l. 6s. 8d.	l.	s. d.			
Once ploughing, at 6s. per acre —	3	0 0			
Harrowing and ſowing, at 1s. 6d. per acre	0	15 0			
Seed, four buſhels per acre, at 2s. per buſhel — — — — — —	4	0 0			
Weeding, at 1s. per acre — —	0	10 0			
Cutting, raking, and carrying, at 3s. 2d. per acre — — — —	1	11 8			
Graſs-ſeeds, at 3s. per acre — —	1	10 0	11	6	8
Third and fourth years lying in graſs coſt nothing,			44	11	8
So that the expence of ten acres in four years comes to 44l. 11s. 8d. and in twenty years to			222	18	4
Firſt year's produce is half a load of wheat per acre, at 7l. per acre — — — —			35	0	0
Second year's produce is two quarters of barley per acre, at 1l. per acre — — —			20	0	0
Third and fourth year's graſs is valued at 1l. 10s. per acre — — — — —			15	0	0
So that the produce of ten acres in four years is			70	0	0
And in twenty years it will be — — —			350	0	0
Deduct the expence — — — — —			222	18	4
And there remains clear profit on ten acres in twenty years by the old way — — —			127	1	8

II. In the New Way.

Firſt year's extraordinary expence is					
For ploughing and manuring the land, the ſame as in the old way — —			22	0	0
Ploughing once more, at 4s. per acre	2	0 0			
Seed, nine gallons per acre, at 4s. per buſhel — — — —	2	5 0			
Drilling, at 7d. per acre — —	0	5 10			
Hand-hoeing and weeding, at 2s. 6d. per acre — — — —	1	5 0			
Horſe-hoeing, ſix times, at 10s. per acre — — — — —	5	0 0			
Reaping, binding, and carrying in, at 6s. per acre — — —	3	0 0			
The ſtanding annual charge on ten acres is — — — — —	13	15 10			
Therefore the expence on ten acres in twenty years is — — —			275	16	8
Add the extraordinaries of the firſt year, and the ſum is — — — — — —			297	16	8
The yearly produce is at leaſt two quarters of wheat per acre, at 1s. 8d. per quarter, which on ten acres in twenty years amounts to			560	0	0
Therefore, all things paid, there remains clear profit on ten acres in twenty years, by the new way — — — — — — —			262	3	4

"So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by one hundred and thirty-five pounds one ſhilling and eight-pence, and conſequently is conſiderably more than double thereof: an ample encouragement to practiſe a method whereby ſo great advantage will ariſe from ſo ſmall a quantity of land, in the compaſs of twenty-one years leaſe; one year being allowed, both in the old and new way of preparing the ground.

"It ought withal to be obſerved, that Mr. Tull's huſbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the firſt year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quarters on an acre, yet Mr. Tull himſelf, by actual experiment and meaſure, found the produce of his drilled wheat crop amount to almoſt four quarters on an acre: and, as he has delivered this fact upon his own knowledge, ſo there is no reaſon to doubt of his veracity, which has never yet been called in queſtion. But that we might not be ſuppoſed to have any prejudice in favour of his ſcheme, we have choſen to take the calculations of others rather than his, having no other view in what we have ſaid, than to promote the cauſe of truth, and the public welfare."

HUSK, the ſame with what botaniſts call the calyx, or cup of a flower. See the article CALYX.

HUSSARS, a kind of irregular cavalry, armed with the ſabre and bayonet, are retained in the ſervice of moſt princes on the continent.

HUSSITES, the diſciples of John Huſs, a Bohemian, and curate of the chapel of Bethlehem at Prague; who, about the year 1414, embraced and defended the opinion of Wickliff of England, for which he was cited before the council of Conſtance, and, refuſing to renounce his ſuppoſed errors, he was condemned to be burnt alive, which ſentence was accordingly executed upon him at Conſtance.

HYACINTH, hyacinthus, in botany, a genus of plants, the flower of which conſiſts of a ſingle campanulated petal, divided into ſix reflex ſegments at the limb: the fruit is a roundiſh capſule, lightly ridged with three corners, and divided into three cells, each of which uſually contains two roundiſh ſeeds.

There is a great variety of theſe beautiful flowers, all of which are propagated by ſeeds, or off-ſets from the old bulbs.

HYACINTH, in natural hiſtory, a genus of pellucid gems, whoſe colour is red, with an admixture of yellow.

HYACINTHIA, an ancient Grecian feſtival, obſerved at Amyclæ in Laconia, in the month Hecatombæon, in memory of the beautiful young Hyacinthus, ſon of Amyclos, king of Sparta.

HYADES, in aſtronomy, ſeven ſtars in the head of the bull, famous among the poets for bringing on rain both at the riſing and ſetting.

The word is Greek, and derived from υω, to rain.

The principal of them is in the left eye, by the Arabs called Aldebaran.

HYDATIS, or HYDATIDES, in medicine, a little tranſparent veſicle, or bladder full of water, which is ſometimes found ſingly, and ſometimes in cluſters, upon the liver, and various other parts, eſpecially in dropſical conſtitutions.

The word is Greek, υδατις, and derived from υδωρ, water.

But hydatis, in a particular ſenſe, implies a diſeaſe of the eye-lid, called alſo aquula, wherein a preternatural pinguious ſubſtance is ſeated under the ſkin of the eye-lid.

St. Yves informs us that there ſometimes comes on the edge of the cartilages of the eye-lids, or on the conjunctiva, an elevation like the bladders that appear on the ſkin after burns. Sometimes a ſeroſity is extravaſated between the conjunctiva and the membrane that covers it, a kind of wrinkle appearing in the movement of the eye.

When this ſwelling ſeizes only part of the conjunctiva, or edge of the eye-lid, prick it dexterouſly with the point of a lancet, and lay it open according to the longitudinal direction of the tumor.

When all the circumference of the globe is filled with water, the conjunctiva becomes red: in this caſe the patient muſt be let blood. When the ſeroſity diminiſhes, let him be purged, and a proper collyrium applied to his eye.

HYDATOIDES, the ſame with the aqueous humour of the eye. See EYE.

HYDATOSCOPY, *Hydatoſcopia*, called alſo HYDROMANCY, in antiquity, a kind of divination, or method of foretelling future events by means of water.

The word is Greek, and formed of υδατ@, the genitive of υδωρ, water, and σκοπεω, to view or conſider.

HYDRA, in aſtronomy, a ſouthern conſtellation imagined to repreſent a water-ſerpent.

The number of ſtars in this conſtellation in Ptolemy's catalogue is twenty-five, and in the Britannic catalogue ſixty-eight.

HYDRAGOGUES, purgative medicines that evacuate a large quantity of watery or ſerous humour.

The word is formed from the Greek, υδραγωγ@, and derived from υδωρ, water, and αγω, to drive, or bring away.

In general all ſudorific, aperient, and diuretic medicines are hydragogues.

HYDRARGYRUM, a name given to mercury or quickſilver. See the article MERCURY.

HYDRAULICS, that part of ſtatics which conſiders

the motion of fluids, with the application thereof, particularly in artificial water-works.

The word is Greek, υδραυλις, an organ, and formed of υδωρ, water, and αυλος, a pipe, as, at the firſt invention of organs, a fall of water was employed to produce a wind to ſound them, the inventor being unacquainted with the method of applying bellows thereto.

HYDRELÆUM, in pharmacy, a mixture of oil and water, which Galen reckons refrigerating.

The word is Greek, and compounded of υδωρ, water, and ελαιον, oil.

Taken inwardly, it provokes vomiting; and, externally, it is anodyne, and promotes ſuppuration.

HYDRENTEROCELE, in ſurgery, a kind of tumor or hernia, where there is a dropſy of the ſcrotum, complicated with a deſcent of the inteſtine.

The word is Greek, and compounded of υδωρ, water, εντερον, an inteſtine, and κηλη, a tumor.

HYDROCANISTERIUM, an engine which ſpouts water in great quantities, and to conſiderable heights, in order to extinguiſh accidental fires in houſes. See ENGINE.

HYDROCELE, *Hernia*, in ſurgery, a ſwelling or dropſy in the ſcrotum. See HERNIA.

HYDROCEPHALUS, in ſurgery, a preternatural tumor of the head ariſing from preternatural lymph.

The word is Greek, and compounded of υδωρ, water, and κεφαλη, the head.

It is of two ſorts, internal and external; internal, when the water is collected within the bones of the cranium; external, when retained between the ſkin and cranium. The firſt kind is rarely ſeen but in new-born infants, who are generally in great danger: for, upon an inciſion, the lymph is no ſooner diſcharged, than the infant dies, as experience has too often convinced us. If the diſtemper be recent, it will be more adviſeable to repeat gentle purges, whilſt a large compreſs dipped in lime-water, ſpirit of lavender, or Hungary-water, is applied outwardly.

Though an external hydrocephalus be not without danger, it is more eaſily cured than the other; and this is to be attempted by internal and external remedies, ſuch as cathartics, diaphoretics, diuretics, attenuating and corroborating medicines for internal uſe; and externally apply digeſtive aromatic bags made with marjoram, origanum, mother of thyme, pennyroyal, chamomile, &c. warm to the head, and ſecured by a proper bandage.

Further it is proper to apply an errhine or cephalic ſnuff, and chew tobacco, to diſcharge the lymph from the head. Laſtly, ſome foment with the fumes of burning ſpirits of wine: but if all theſe fail, firſt by bliſters behind the ears and on the neck; and if this fail, cup the parts. Longitudinal ſcarifications much better promote the diſcharge: after this, the wounds muſt be dreſſed with lint ſpread with a digeſtive ointment; and to keep them open, add ſometimes a little red precipitate. Having thus removed the diſorder, the wounds ſhould be healed with a vulnerary balſam, and the patient kept to proper internal medicines, and a regular diet.

HYDROCHARIS, the little water-lilly, in botany, a genus of plants, the male flower of which has a ſpatha, and is compoſed of three large, plain, and roundiſh petals; the female flower is like the male one, only without any ſpatha: the fruit is a coriaceous and roundiſh capſule, conſiſting of ſix cells, in which are contained a great number of very ſmall and roundiſh ſeeds.

HYDROCOTYLE, marſh-penny-wort, in botany, a genus of plants, the univerſal corolla of which is uniform in figure, though not in ſituation; and the ſingle corollæ are formed of five ovato acute, patent petals: the fruit is orbicular, erect, and compoſed of two compreſſed and ſemi-orbicular ſeeds.

This plant is common with us in damp places, and is ſuſpected of hurting ſheep that feed on it; whence it is ſometimes called white-rot.

HYDROGRAPHY, that part of geography which conſiders the ſea as it is navigable.

The word is Greek, and derived from υδωρ, water, and γραφω, to deſcribe.

It teaches how to meaſure the ſea; gives an account of its tides, counter-tides, currents, ſoundings, bays, &c. as alſo its rocks, ſhelves, ſands, promontories, harbours, diſtances from port to port, with every thing remarkable out at ſea, or on the coaſt.

HYDROMANCY, the art of foretelling future events by means of water; the ſame as hydatoſcopy.

The word is Greek, and formed of υδωρ, the water, and μαντεια, divination.

The other kinds of divination relative to fire, air, and earth, are denominated pyromancy, aeromancy, and geomancy.

HYDROMEL, *Hydromeli*, among phyſicians, water impregnated with honey, either before or after fermentation: that made by fermentation is called vinous hydromel, or mead, and is eſteemed good for the gravel. See HONEY.

The word is Greek, and compounded of υδωρ, water, and μελι, honey.

HYDROMETER, an inſtrument to meaſure the gravity, denſity, velocity, force, &c. of water and other fluids. See the articles WATER and FLUID.

The hydrometer is one of the moſt uſeful inſtruments of the philoſophic kind; for though the hydroſtatical ballance be the moſt general inſtrument for finding the ſpecific gravities of all ſorts of bodies, yet the hydrometer is beſt ſuited to find thoſe of fluids in particular, both as to eaſe and expedition.

This inſtrument ſhould be made of copper, ſince ivory imbibes ſpirituous liquors, and thereby alters its gravity; and glaſs is apt to break. The moſt ſimple kind, uſed for finding the ſtrength of ſpirits, conſiſts of a copper-ball B*b* (plate LXXIV. *fig.* 5.) with a braſs-wire, A B, $\frac{1}{4}$ of an inch thick, ſoldered into it. The upper part of this wire being filed flat on one ſide, is marked proof at *m*, becauſe it ſinks exactly to this mark in proof-ſpirits. There are other two marks at A and B, to ſhew whether the liquor be $\frac{1}{10}$ above or below proof, according as the hydrometer ſinks to A or emerges to B, when a braſs weight as C or K has been ſcrewed on at the bottom *c*. There are alſo weights to be ſcrewed on, for ſhewing the ſpecific gravities of fluids quite to common water. The round part of the wire above the ball, may be marked ſo as to repreſent river-water when it ſinks to R W, (*fig.* 6.) the weight which fits the inſtrument for river-water being ſcrewed on at *c*: alſo when put into ſpring-water, mineral-water, ſea-water, and water of ſalt-ſprings, it will emerge or riſe gradually to the marks S P, M I, S E, S A; and, on the contrary, when put into Briſtol-water, rain-water, port-wine, and mountain-wine, it will ſucceſſively ſink to the marks *br*, *ra*, *po*, *mo*.

Another kind, which ſerves to diſtinguiſh the ſpecific differences of fluids to great nicety, conſiſts of a large hollow ball B, (*fig.* 7.) with a ſmaller ball *b* under it, partly filled with quick ſilver or ſmall ſhot, and ſcrewed on to the lower part of the former, in order to render it but little ſpecifically lighter than water: it has alſo a ſmall ſhort neck at C, into which is ſcrewed the graduated braſs-wire A C, which by its weight cauſes the body of the inſtrument to deſcend in the fluid, with part of the ſtem.

When this inſtrument is ſwimming in the liquor, contained in the jar I L M K, the part of the fluid diſplaced by it, will be equal in bulk to the part of the inſtrument under water, and equal in weight to that of the whole inſtrument. Suppoſe the weight of the whole were 4000 grains, then it is evident we can by this means compare together the different bulks of 4000 grains of various ſorts of fluids. For if the weight A be ſuch as ſhall cauſe the aræometer to ſink in rain-water, till its ſurface comes to the middle point of the ſtem 20; and if, after this, it be immerſed in common ſpring-water, and the ſurface is obſerved to ſtand $\frac{1}{10}$ of an inch below the middle point 20; it is evident that the ſame weight of each water differs in bulk only by the magnitude of $\frac{1}{10}$ of an inch in the ſtem.

Now ſuppoſe the ſtem were ten inches long, and weighed one hundred grains, then every tenth of an inch would be one grain weight; and ſince the ſtem is of braſs, and braſs is about eight times heavier than water, the ſame bulk of water will be equal to $\frac{1}{8}$ of a grain; and conſequently to the $\frac{1}{8}$ of $\frac{1}{32000}$ part, that is, a 32000th part of the whole bulk, which is a degree of exactneſs as great as can be deſired. Yet the inſtrument is capable of ſtill greater exactneſs, by mak-

ing the ſtem or neck conſiſt of a flat thin ſlip of braſs, inſtead of one that is round or cylindrical: by this means we increaſe the ſurface, which is the moſt requiſite thing; and diminiſh the ſolidity, by which the inſtrument is rendered more exact.

In order to adapt this inſtrument to all ſorts of uſes, there ought to be two different ſtems to ſcrew on and off in a ſmall hole at *a*. One ſtem ſhould be ſuch a niee thin ſlip of braſs, or rather of ſteel, like a watch-ſpring ſet ſtraight, as we have juſt mentioned, on one ſide of which ought to be the ſeveral marks or diviſions, to which it will ſink in various ſorts of waters, as rain-water, river-water, ſpring-water, ſalt ſpring-water, &c. And on the other ſide you mark the diviſion to which it ſinks in various lighter fluids, as hot Bath-water, Briſtol-water, Lincomb-water, Chelten-water, port-wine, mountain, madeira, and various other ſorts of wine. But in this caſe the weight A on the top muſt be a little leſs than before, when it was uſed for the heavier waters.

But, in caſe of trying the ſtrength of ſpirituous liquors, a common cylindric ſtem will do beſt, becauſe of its ſtrength and ſteadineſs; and this ought to be ſo contrived that, when immerſed in what is called proof-ſpirit, the ſurface of the ſpirit may be upon the middle point 20; which is eaſily done by duly adjuſting the ſmall weight A on the top, and making the ſtem of ſuch a length that, when immerſed in water, it may juſt cover the ball, and riſe to *a*; but, when immerſed in pure ſpirit, it may ariſe to the top at A; then by dividing the upper and lower parts *a* 20, A 20, into ten equal parts each, when the inſtrument is immerſed in any ſort of ſpirituous liquor, it will immediately ſhew how much it is above or below proof.

This proof ſpirit conſiſts of half water and half alcohol, or pure ſpirit, that is, ſuch as when poured upon gunpowder, and ſet on fire, will burn all away, and permit the powder to take fire, which it will, and flaſh as in the open air. But if the ſpirit be not ſo highly rectified, there will remain ſome phlegm or water, which will make the powder wet, and unfit to take fire. This proof-ſpirit of any kind, weighs ſeven pounds twelve ounces per gallon.

The common method of ſhaking the ſpirits in a vial, and by raiſing a crown of bubbles, to judge by the manner of their riſing or breaking away whether the ſpirit be proof or near it, is very precarious and capable of great fallacy. There is no way ſo eaſy, quick, certain, and philoſophical, as this by the aræometer, which will demonſtrate infallibly the difference of bulks, and conſequently ſpecific gravities, in equal weights of ſpirits, to the 30, 40, or 50 thouſandth part of the whole, which is a degree of accuracy, beyond which nothing can be deſired.

HYDROMETRY, *Hydrometria*, the menſuration of fluids, their gravity, velocity, quantity, &c.

The word is of the ſame original with the preceding. It includes both hydroſtatics and hydraulics.

HYDROMPHALUS, in medicine and ſurgery, a tumor of the navel, containing water. See the article HERNIA.

The word is Greek, and derived from ὑδωρ, water, and ὀμφαλὸς, the navel.

The hydromphalus, when viewed between the eye and the light, is found to be tranſparent. It is diſcuſſed by emollient and reſolutive medicines, and alſo by a puncture in the middle of the navel.

HYDROPARASTATÆ, a ſect of heretics, the followers of Tatian.

This ſect were called alſo Encratitæ, Apotactitæ, Saccophori, Severiani, and Aquarians.

The Hydroparaſtatæ were a branch of the Manichees, whoſe diſtinguiſhing tenet was, that water ſhould be uſed in the euchariſt inſtead of wine.

HYDROPHOBIA, in medicine, a dread of water, which is a ſymptom ariſing in a perſon who has been bitten by a mad dog, or other mad animal.

The word is Greek, and compounded of ὑδωρ, water, and φοβέω, to fear.

The ſymptom is not peculiar to this diſtemper, though it be always an attendant; for we meet with ſeveral inſtances of fevers accompanied with a dread of water.

Dogs, wolves, and foxes, are moſt frequently affected with this madneſs, and that without any previous bite from another animal. With reſpect to the propagation of this diſtemper from brutes to mankind, the diſeaſe ſeems to be inoculated by the bite into the animal, which receives it; for the wound feſters ſome little before or about the time the diſtemper begins to appear. Something very like this happens in the inoculation of the ſmall-pox.

The ſigns of approaching madneſs in dogs are, according to Boerhaave; they become dull, and endeavour to hide themſelves; they are mute, as to their bark; but they make a kind of murmuring noiſe, refuſing, at the ſame time, meat and drink; they fly at ſtrangers; but in this ſtage, which is the firſt, they remember and reſpect their maſters; their ears and head hang, and they walk nodding, as if overpowered by ſleep. A bite received at this time is very dangerous; but not of the worſe kind. Then they begin to pant and hang out their tongue, to emit a great deal of froth from the mouth, which they keep perpetually open; ſometimes they walk ſlowly, and as if half aſleep; and then ſuddenly run, but not always directly forward: at laſt they forget their maſters; mean time their eyes look dull, full of tears and red; their tongue is of a lead colour; they are ſuddenly extenuated, and now rage exceſſively. They ſeldom ſurvive this ſtage thirty hours; and a bite received at this time, as Boerhaave ſays, is incurable. But the more raging the animal is, the more dangerous is the bite, and the more violent are the ſubſequent ſymptoms, and *vice verſa*.

Two other circumſtances, which Boerhaave has omitted, are, that all other dogs, upon ſmelling the dog going mad, will avoid him, and run away with horror, ſhaking their heads with ſome vehemence. The other circumſtance is, that the tone of the dog's voice, when he barks, will be quite altered from what it was, and ſeem hollow and hoarſe. And though, as Boerhaave obſerves, the dog may be mute in the dumb madneſs, yet it is more frequently found, that a dog, eſpecially if confined, ſhall bark for a day or two without ceaſing. There is no poiſon known which produces ſuch terrible effects as that communicated by a mad animal, nor which induces ſuch a change in a perſon who receives it; or which rages with ſuch violence, and ſo ſuddenly, when it once begins to act.

In a perſon affected with this diſorder, among other extraordinary ſymptoms, the approach of any liquor to the body, eſpecially to the tongue and lips, produces an incredible uneaſineſs, trembling, convulſions, and a ſtate next to direct madneſs: and at the ſame time the patient is racked with an inſatiable thirſt.

In general, Boerhaave affirms, that there is no certain preſervative againſt this diſorder yet known; and that there is no example, that can be depended upon, of any one having been recovered, who was once ſo far gone as to dread water. This author adds, that it is much to be lamented, that after the common methods have been put in practice perpetually without ſucceſs, for ſo many ages, others have not been tried. All the celebrated remedies for this purpoſe, he adds, owe their reputation either to barren ſpeculation, or too great confidence in the reports of others.

His own directions, however, are, 1. As ſoon as the poiſon is received into the body, the part affected, and thoſe adjacent thereto, ſhould have deep ſcarifications made in them. Then large cupping-glaſſes to be applied, or the part to be burnt pretty deep with the actual cautery, and afterwards kept in continual ſuppuration. During the whole of this time, the part is, without interruption, to be fomented with a pickle of ſea-ſalt and vinegar. 2. The cloaths, &c. which have come near the poiſon to be thrown away. 3. The patient is, immediately after receiving the misfortune, to be thrown headlong into the ſea, or ſome river, with threatening words, and other circumſtances capable of ſtriking terror into him; for which purpoſe he is frequently to be immerſed in the water, and again taken up: for the good effects are only produced by the dread and conſternation into which the mind is thrown. He is frequently to be purged with rhubarb, agaric, and the juice of elder-bark. 4. Let the patient have a gentle ſweat excited every morning before eating.

eating. 5. His feet and hands are to be daily fomented in a bath of water. Laſtly, let him frequently drink cold water, till he vomit it up: uſe acidulated liquors often: his diet muſt be moiſt, light, and laxative, and take them ſo liberally as to vomit them again. He muſt abſtain from large quantities of aromatic ſubſtances, wine, &c. violent exerciſe of body, and all commotions of mind.

The cure is principally to be attempted in the firſt ſtage, or the beginning of the ſecond. It ſeems probable, ſays he, the following method may be of ſome efficacy, eſpecially as it is confirmed by ſome few experiments. Immediately upon the ſigns of approaching madneſs, the caſe is to be treated as extremely inflammatory; wherefore a large quantity of blood muſt be taken away by a large orifice, even till the patient is faint: then directly inject nitrous clyſters, mixed with a little vinegar. Let theſe be repeated boldly, and more frequently than is conſiſtent with prudence in other caſes. After this the eyes are to be blindfolded, and he thrown into a cold pond, or cold water thrown upon him, till he be no longer afraid of it. Then let him be immediately forced to drink a large quantity of water; and toward the evening of the ſame day let a ſleep be procured.

We have an account of remedies for this malady in the Philoſophical Tranſactions; one of which is the lichen cinereus terreſtris, or aſh-coloured liverwort, which has been taken into the College Diſpenſatory, under the title of *Pulvis Antilyſſus*, and is the celebrated remedy publiſhed by Dr. Mead, with ſome variation in the proportion of the pepper. The directions, as made public, are, firſt to take away nine or ten ounces of blood; and then take of powdered aſh-coloured liverwort, four drams, and of the powder of black pepper, two drams: mix theſe together, and divide into four doſes; one of which is to be taken faſting for four days ſucceſſively, in half a pint of tepid cow's milk. After taking theſe four doſes, the patient is to be put faſting every morning for a month, either into a cold bath, cold ſpring, or river, remaining therein with his head above water, not longer than half a minute, if the water be exceſſively cold. Then let him bathe thrice a week for fifteen days.

Boerhaave, in his Aphoriſms, treating of the canine madneſs, would have us not to deſpair of diſcovering a peculiar antidote againſt this ſingular kind of poiſon: and this, ſays he, we are encouraged to hope for, from the certain inſtances we already have of remedies effectual againſt particular ſorts of poiſon. Accordingly he had a mind to try what effect mercury would have upon animals under canine madneſs; and from ſeveral experiments, he found it prove ſucceſsful, by adminiſtering ſome grains of turpeth mineral made into boluſes. He alſo mentions the remedy which M. Deſault tried with conſtant ſucceſs in the hydrophobia, which is a mercurial ointment made of one third part of mercury revived from cinnabar, one third part of human fat, and as much of hog's lard. One or two drams of this ointment at a time ſhould be rubbed by intervals, or ſucceſſively, upon and about the wound. As a farther confirmation of the efficacy of mercury in the canine madneſs, he takes notice of a medicine Mr. Cobb of Buſſelton, near Briſtol, brought from Tonquin, which is much celebrated in the Eaſt-Indies as efficacious in this diſtemper; this is a native and factitious cinnabar, of each twenty-four grains; muſk, ſixteen grains, powdered and mixed well together. This powder is to be taken all at once in a tea-cup of arrack, which is ſaid to ſecure the patient for thirty days: after which time the doſe is to be repeated in the ſame manner; but it ſhould be done as ſoon as poſſible after the bite is received: but if the patient have any ſymptoms of the diſeaſe, the ſecond doſe muſt be repeated three hours after the firſt; and this is ſaid to be ſufficient for a cure.

HYDROPIC, a dropſical patient; or a perſon ſwelled and bloated with the abundance of water. See the article DROPSY.

HYDROPOTA, in medicine, a perſon who drinks nothing but water.

It has long been controverted among phyſicians, whether or no the hydropotæ live longer than other perſons.

HYDROPS, in medicine, the ſame with dropſy. See the article DROPSY.

HYDROSCOPE, an inſtrument anciently uſed for the meaſuring of time.

The hydroſcope was a kind of water-clock conſiſting of a cylindrical tube, conical at bottom; the cylinder was graduated, or marked out with diviſions, to which the top of the water becoming ſucceſſively contiguous, as it trickled out at the vertex of the cone, pointed out the hour. See CLEPSYDRA.

HYDROSTATICAL BALLANCE, a kind of ballance contrived for the eaſy and exact finding the ſpecific gravities of bodies, both liquid and ſolid. See the article *Hydroſtatical* BALLANCE.

Bradford's New HYDROSTATICAL INSTRUMENT, a new invention for weighing coin, and diſcovering its defect either of weight or purity.

It conſiſts of a thin, flat, braſs-ruler, about half a foot long; on each ſide of which are two graduated lines, thoſe on the upper ſide being marked A and W (plate LXXIV. *fig.* 8) and thoſe on the under ſide B and W. (*fig.* 9) There is alſo a ſmall chain and pincers wherein to fix any piece of money intended to be weighed and proved; together with two pair of center pins, marked A and B, (*fig.* 10.) whereof the former pair A are to be uſed for proving all pieces of gold not exceeding the value of 36 s. and the other pair marked B, for all pieces from 36 s. to 72 s. or 3 l. 12 s. Laſtly, there is a ſliding-piece or index C, (*fig.* 10.) by the motion of which backwards and forwards upon the ruler, the value of any piece ſuſpended in the pincers is found upon the graduated lines already mentioned; whereof thoſe marked A and B are called ſtatical lines, as being calculated for weighing the piece in air; and thoſe marked W, W, are called hydroſtatical lines, as ſerving to point out the alloy or adulteration of the piece weighed. A whole diviſion on each line, is equal to the weight or value of 1 s. in gold; a half diviſion to 6 d. and a quarter diviſion to 3 d.

To prove a guinea: firſt ſuſpend it in the pincers, and then placing the inſide of the ſliding-piece C to 21 on the line A, on the upper ſide of the ruler, which muſt move freely on the center-pins marked A; and if the guinea and ſliding-piece exactly ballance each other, the guinea is full weight: if not, move the ſlider backward or forward, till they equiponderate, and the diviſion cut by the inſide of the ſlider is the true weight; for inſtance, ſuppoſe it reſts at 20 $\frac{1}{2}$, then does the guinea weigh only 20 s. 6 d. In the next place, to prove the alloy of the piece, let the ſlider be brought to the diviſion 20 $\frac{1}{2}$ upon the hydroſtatical line marked W; for whatever diviſion is cut by the ſlider, in weighing on the ſtatical line, it muſt be placed at the ſame on the hydroſtatical line adjoining. Then let the piece, together with the pincers and the braſs-link whereon it is ſuſpended, be immerſed in water (*fig.* 10.) as far as the notch in the ſaid link; and if the inſtrument acts in equilibrio, or the piece ſink deeper in the water, the guinea is ſtandard-gold; but if the ſlider muſt be moved farther backward before it will equiponderate, the guinea is adulterated. If alloyed with ſilver, allow 2 s. for every penny it wants in the hydroſtatical weight; and then, if the number of pence the piece is deficient in weight hydroſtatically, when doubled exceed the number of ſhillings it weighs ſtatically, you may conclude it is adulterated with ſome baſer metal than ſilver. However, a more ſpeedy method of diſcovering whether a piece of gold be adulterated or not without moving the ſlider more than once, is this: when you have weighed a piece ſtatically, bring the ſlider to the diviſion on the hydroſtatical line expreſſing its weight, and immerſing the piece and pincers as before, ſo that the ſurface of the water may be exactly at the notch or mark on the long link, if the inſtrument doth not then equiponderate, gently lower your hand that holds the fluid till the inſtrument comes to an equilibrium; at which time, if the guinea be a counterfeit, great part of the pincers will appear above water; and if a 36 s. piece be tried, not only the pincers, but a ſmall part of the coin will appear above the ſurface, if the piece be counterfeit. This laſt method is ſufficiently near the truth for common practice.

If you ſhould have occaſion to weigh and prove a very ſmall piece of gold, as 2s. 3d. or 4s. 6d. the method is to put the ſaid piece in the pincers, with ſome other piece that has been proved before; by which means, the weight and alloy of the ſmall piece may be eaſily diſcovered, as above. And if the piece be above 36 s. then the ſlider is to be placed according to the diviſions of the ſtatical and hydroſtatical lines on the under ſide of the inſtrument; which is fitted to the ſtandard of the mint, that makes the guinea to weigh 129 grains.

HYDROSTATICS, that part of mechanics which conſiders the gravity and æquilibrium of fluid bodies, particularly water, and of ſolid bodies immerſed therein.

The word is Greek, and compounded of υδωρ, water, and ςατικη, the ſcience of weights, which is derived from ιςημι, to eſtabliſh or determine.

Mr. Boyle has applied hydroſtatics in examining and proving the goodneſs and purity of metals, minerals, &c. particularly fluids, in his Hydroſtatica. See *Hydroſtatical* BALANCE.

As to the laws of hydroſtatics, with the application thereof; ſee FLUID.

Hydroſtatics and hydraulics are treated by ſome authors promiſcuouſly.

Thoſe who are acquainted but the leaſt with the ancient Egyptians, know that they found the way to keep their river within proper bounds, and to make a good uſe of its ſalutary waters, whether it were by ſpreading them over their plains, or raiſing them to conſiderable heights.

Among the Greeks, Ariſtotle was the firſt that wrote of the æquilibrium of fluids, and reduced the flight of birds, the motion of fiſhes, and the direction or ſteerage of ſhips, to the rules of mechanics.

It is well known with what addreſs Archimedes, who came after Ariſtotle, diſcovered the cheat of the goldſmith of king Hiero. The latter, ſuſpecting that the workman had allayed the gold with more ſilver than was neceſſary, ſent to the philoſopher to examine and detect the fraud. He was long at a loſs to think of any method of doing it; till one day getting into a tub full of water to bathe himſelf, he obſerved, that as he entered the tub, the water ran out; and he immediately ſaw it muſt follow, that if the tub were full, the water which ran out upon his immerſion, muſt be equal in bulk to his body.

Thence the philoſopher began thus to reaſon: If I immerſe the crown in a veſſel full of water, it will protrude as much as is equal to its bulk. If after this I immerſe the ſame weight of pure gold and pure ſilver, I ſhall get bulks of water equal to each; conſequently, having the bulks of gold, ſilver, and crown of equal weight, I have the ratio of the ſpecific gravities, which are known to be as the bulks inverſely. Then to find the ratio of gold to the ſilver in the crown, he proceeded in ſome ſuch manner as the following:

Suppoſe a veſſel filled with water to a certain height, and that the maſs, M, of gold, equal in weight to the crown, being immerſed into the water, raiſes the ſurface thereof a certain height, H; and after that, the maſs, *m*, of ſilver of the ſame weight immerſed raiſes the ſurface the height *h*; and laſtly, if the crown be immerſed, the ſurface of the water ſhall be raiſed to ſome height, *p*, between the former heights. Hence the proportion of the bulks of the gold and ſilver in the crown may be determined.

For it is evident, that if the crown had been all gold, it would have raiſed the ſurface of the water to the height H; but it raiſed that ſurface to a greater height *p*; therefore *p*—H is as the bulk of gold in the crown: and again, had the crown been of ſilver only, it would have raiſed the ſurface of the water to the height *h*; conſequently *h*—*p* is as the bulk of ſilver in the crown: hence the bulk of gold in the crown is to that of ſilver, as *p*—H to *h*—*p*. It is ſaid that Archimedes offered a hecatomb of oxen to Jupiter for inſpiring him with the thought.

This famous mathematician alſo invented that cochlea or ſcrew, which, by the motion of an inclining cylinder, makes the water riſe, while the other falls. The water acts by its own gravity in this ſimple machine, but it cannot be carried very high. See the article *Archimedes's* SCREW.

Cteſibius, by making uſe of a more compounded machine, which has kept the name of its inventor, knew how to make the water riſe to all ſorts of heights; and is in uſe at preſent, as are the ſeveral ſorts of pumps. But of the inventions of the ancients, there is none of greater importance than that of water-mills; for, as Vitruvius deſcribes them, they ſeem to have reſembled ours pretty much. It is true they were not ſo common then as they are now-a-days.

The moderns knew but little of hydroſtatics before Galileo. This great man, being of the ſame opinion with the ancients, that there was no vacuum in nature, attributed the elevation of the water in the ſucking-pump to the abhorrence of a void. Torricelli, his diſciple, remarked, that when a tube, cloſe at the upper-end, was immerſed into a veſſel full of mercury, the mercury remained ſuſpended in the tube at a certain height, and that it filled into the veſſel, when the tube was open. Torricelli communicated this experiment, but without referring it to the true cauſe; but by repeating it often, he conjectured that it might be the effect of the weight of the air.

M. Paſcal laid hold of the notion, and after being aſſured of the fact by experiments which he made, and publiſhed anno 1647, he endeavoured in 1648, to certify himſelf of the cauſe: and at length, from his experiments, he knew what Torricelli had only conjectured: and what the great duke's mathematician had ſaid doubtfully, M. Paſcal demonſtrated by the famous experiments he made on the pit of Domme, and afterwards in the treatiſes he publiſhed.

The experiments which have been made, in order to know the properties of fluids, moved M. Marriotte to make ſeveral obſervations which had not been touched on before; whereby he enriched hydraulics with a number of diſcoveries on the meaſure and expence of conveying water, according to the different heights of the reſervoirs and their various adjuncts. Afterwards he examined what concerns the conducting of water, and the ſtrength requiſite in pipes for reſiſting their different gravities.

M. Marriotte had a good deal of knowledge and dexterity in removing difficulties, and was ſingularly happy in making experiments, which he performed for the moſt part at Chantilly, and at the Royal Obſervatory. He nevertheleſs neglected what concerned the different pumps and other machines which might raiſe water. This part of the hydroſtatics had been touched but very imperfectly when the chevalier Morland undertook to treat of it. If he hath not exhauſted the ſubject, he has at leaſt given light enough for carrying on the theory and practice of it very far.

HYGIEINE, that branch of medicine which preſcribes rules for the preſervation of health; it may be divided into prophylactice, which foreſees and prevents diſeaſes; ſynteritice, employed in preſerving health; and analeptice, whoſe office is to reſtore health.

The word is Greek, υγιεινη, and derived from υγιης, ſound.

HYGROMETER, or HYGROSCOPE, a machine whereby to meaſure the degrees of the dryneſs or moiſture of the air.

The word is Greek, and compounded of υγρος, moiſt, and μετρεω, to meaſure.

In the Philoſophical Tranſactions we have ſeveral methods of conſtructing hygroſcopes.

Mr. Molyneux gives the following: AB (plate LXXV. *fig.* 1.) is a whipcord about four feet long, tied faſt to the end of the hook A. At the end of this whipcord hangs the weight 6, about a pound, or ſomething more: this weight is ſo fitted at the end to receive and carry the index D. Under theſe there is placed a graduated circle on the board EF, fixed by a bracket againſt the wall.

The moiſture of the air twiſts the cord, and gives a motion to the index over the diviſions in the graduated circle; and again, as the air grows more dry, the cord untwiſts and brings back the index by a contrary motion.

The rope A B ſhortens and lifts up the weight C by way of a ſcrew, and conſequently muſt give a circular motion to the index.

One of the grand defects of all hygrometers hitherto invented is, that they grow weak with age, and do not ſo nicely obey the alterations of the air. The alterations alſo of the air may give this kind of hygroſcope more than one turn. To remedy this, the index D has two complete turns: the point A, as being fixed, has no turn; therefore the middle point G has but one turn; and conſequently if it be hung up at the point G, or no longer than G D, half the former length, the index D will have but one turn. What is here ſaid of two turns, and the middle point G, may be accommodated to any other number of turns and points in the cord.

Mr. Gould obſerves that, when oil of vitriol is faturated in the moiſteſt weather, it afterwards retains or loſes its acquired ſtate, as the air proves more or leſs moiſt. Thus one grain, after its full increaſe, often varied the equilibrium ſo ſenſibly, that the tongue of the ballance of 1 ½ inch long, deſcribed an arch of variation to ⅓ of an inch compaſs; which arch would have been 2⅔ inches, had the tongue been but one foot in length, even with that little quantity of liquor: ſo that, if more liquor expanded under a large ſurface be made uſe of, the minuteſt alteration of weather muſt needs very much affect it; and a bare pair of ſcales will afford a hygroſcope as nice, perhaps, as any yet known.

This ballance may be contrived two ways; either ſuch whoſe pin ſhould be in the middle of the beam (*fig.* 2.) with a very ſlender tapering tongue of a foot or a foot and a half long, pointing to the diviſions on a broad arched plate fixed above in the handle; or elſe the ſcale with the liquor may be hung to a point of the beam (*fig.* 3.) very near the pin, and the other extreme made ſo long as to mark a large arch on a board placed conveniently for that purpoſe. The ſcale in either may be a concave glaſs of four or five inches diameter. Laſtly, on the diviſion of the arches ſhould be inſcribed the different temperature of the air ſhewn by the liquor.

The above author imagines oil of ſulphur per campanum, as alſo oil of tartar per deliquium, and the liquor of fixed nitre, &c. might ſucceed as well as oil of vitriol.

Another hygroſcope, he ſays, may be made of a viol ſtring running upon pullies, and ſuſpending a bullet fixed to the ſhorter end of an index, whoſe other extremity is ſo long as to deſcribe a long arch by the falling and riſing of the bullet upon the ſtretching and ſhrinking of the ſtring; which would be the more nice, were the index faſtened to the center.

But among all the inventions, the following ſeems beſt calculated both for diſpatch and accuracy.

A (*fig.* 4.) repreſents a thin piece of ſponge, ſo cut as to contain as large a ſuperficies as poſſible. This hangs by a fine thread of ſilk, upon the beam B, and is exactly ballanced from another thread of ſilk at D, ſtrung with the ſmalleſt lead ſhot, at equal diſtances, and ſo adjuſted as to cauſe the index E to point at G, in the middle of the graduated arch F, G, H, when the air is in the middle ſtate, between the greateſt moiſture and the greateſt dryneſs. I, ſhews a little table or ſhelf for that part of the ſilk and ſhot which is not ſuſpended to reſt upon.

The word hygroſcope and hygrometer are commonly both uſed in the ſame ſenſe. However, Wolfius makes ſome difference betwixt a hygroſcope and an hygrometer, ariſing from the etymology; the former only ſhewing the alterations of the air, in reſpect of humidity and dryneſs; and the latter meaſuring them.

The word hygroſcope is Greek, and compounded of υγρος, moiſt, and σκοπεω, to view, or conſider.

HYLE, or HYLEC, among alchemiſts, denotes their firſt matter, or the original chaos of things.

HYLEG, or HYLECH, in aſtrology, ſignifies a planet, or the point in the heavens, which at a perſon's nativity is accounted the ſignification of life. See the article NATIVITY.

HYMEN, in anatomy, ſignifies a membrane in general; but it is commonly taken for that circular membraneous fold, with which the anterior extremity of the great canal in virgins, and eſpecially before the firſt eruption of the menſes, is commonly bordered. This fold is of different breadths, more or leſs ſmooth, and ſometimes ſemi-lunar; and in ſome ſubjects leaves but a very ſmall opening, in others a larger; and in all renders the external orifice narrower than the reſt of the cavity. The hymen is formed by the union of the internal membrane of the great canal with that on the inſide of the alæ; it is commonly ruptured after the conſummation of marriage; is quite loſt in delivery; and afterwards only ſome irregular portions of it remain, which, from their ſuppoſed reſemblance to myrtle leaves, have been termed carunculæ myrtiformes. This circle may alſo ſuffer ſome diſorder by too great a flux of the menſes and other particular accidents. *Winſlow.*

HYMN, a religious ſong. The hymns ſung in the Chriſtian church, as diſtinguiſhed from the pſalms, are pieces of poetry compoſed by pious, but not inſpired, authors.

HYOIDES, in anatomy, a forked bone at the root of the tongue; it is ſituated in the middle ſpace between the angles of the lower jaw; it is a little bone, and reſembles, in ſome meaſure, the baſis of the lower jaw.

HYOTHYROIDES, in anatomy, a muſcle of the larynx, which ſerves to raiſe it, and conſtringe the glottis.

HYPÆTHROS, or HYPÆTHRON, in ancient architecture, a kind of temple open at the top.

Vitruvius ſays, it was an open building or portico, which had no roof or covering, as the temple of Jupiter Olympius, built by Caſſatius, a Roman architect at Athens.

HYPALLAGE, among grammarians, a ſpecies of hyperbaton, conſiſting in a mutual permutation of one caſe for another.

HYPANTE, or HYPERPANTE, a name given by the Greeks to the feaſt of the preſentation of Jeſus in the temple.

This word, which ſignifies lowly or humble meeting, was given to this feaſt from the meeting of old Simon, and Anna the propheteſs, in the temple, when Jeſus was brought thither.

HYPATE, in ancient muſic, an appellation given to the loweſt chord of a tetrachord.

HYPER, υπερ, a Greek prepoſition, frequently uſed in compoſition, where it denotes exceſs; its literal ſignification being above, or beyond.

HYPERBATON, in grammar, a figurative conſtruction inverting the natural and proper order of words and ſentences. The ſeveral ſpecies of the hyperbaton are the anaſtrophe, the hyſteron proteron, the hypallage, ſynchyſis, tmeſis, parentheſis, and the hyperbaton, ſtrictly ſo called. See ANASTROPHE, &c.

HYPERBATON, ſtrictly ſo called, is a long retention of the verb, which completes the ſentence.

HYPERBOLA, in geometry, one of the curve lines formed by the ſection of a cone. See CONIC *Sections.*

The plane of every hyperbola, is proportioned by this general theorem:

"As the ſum of the tranſverſe and any abſciſſa, multiplied into that abſciſſa, is to the ſquare of its ſemi-ordinate; ſo is the ſum of the tranſverſe and any other abſciſſa, multiplied into the abſciſſa, to the ſquare of its ſemi-ordinate."

That is, if T S (plate LXXV. *fig.* 5.) be the tranſverſe diameter, and S *a*, S A, abſciſſas, and *b a*, B A, ſemi-ordinates: then is T *a* = T S + S *a*, and T A = T S + S A. And it will be T *a* × S *a* : □ *b a* :: T A × S A : □ B A. That is, T S + S *a* × S *a* : □ *b a* :: T S + S A × S A : □ B A.

Theſe proportions are the common property of every hyperbola, and differ only from thoſe of the ellipſis in the ſigns + and −. See ELLIPSIS.

That is, if we ſuppoſe T S (*fig.* 6.) the tranſverſe diameter, common to both ſections, viz. both the ellipſis and hyperbola.

Then in the ellipſis it will be T S − S *a* × S *a* : □ *a b* :: T S − S A × S A : □ A B. And in the hyperbola it is T S + S *a* × S *a* : □ *a b* :: T S + S A × S A : □ A B as above.

And

And therefore all that is further required in the hyperbola may be found as in the ellipsis, due regard being had to the changing of the signs.

To find the latus rectum or right parameter of any hyperbola.

From the last proportion, take any of the antecedents and its consequent, viz. either $Ta \times Sa : \square ab$. Or, $TA \times SA : \square AB$. To them bring in the transverse TS, for a third term, and by those three find a fourth proportional, as in the ellipsis, and that will be the latus rectum.

To find the focus of any hyperbola.

The focus being that point in the hyperbola's axis, through which the latus rectum must pass, as in the ellipsis and parabola, it may be found by this theorem:

"To the rectangle made of half the transverse into half the latus rectum, add the square of half the transverse; the square root of that sum will be the distance of the focus, from the center of the hyperbola."

To describe a hyperbola in plano.

In order to the easy describing of an hyperbola in plano, it will be convenient to premise the following proposition, which differs from that of the ellipsis only in the signs.

Prop. If from the focus of any hyperbola there be drawn two right-lines, so as to meet each other in any point of the hyperbola's curve; the difference of those lines (in the ellipsis it is their sum) will be equal to the transverse diameter.

That is, if F (*fig.* 7.) be the focus, and it be made $Cf = CF$; then the point f is said to be a focus out of the section (or rather of the opposite section) and it will be $fB - FB = TS$.

If this proposition be truly understood, it must needs be easy to conceive how to describe the curve of any hyperbola very readily by points, when the transverse diameter and the focus are given, or any other data by which they may be found, as in the precedent rules.

Thus: — Draw any straight line at pleasure, in it set off the length of the given transverse TS (*fig.* 8.) and from its extreme points or limits, viz. T, S, set off $Tf = SF$, the distance of the given focus, viz. the point f, without, and F within the section as before; that done, upon the point f, as a center, with any assumed radius greater than TS, describe an arch of a circle; then from that radius take the transverse TS, making their difference a second radius, with which upon the point F, within the section, describe another arch to cut or cross the first arch as at B. Then will that point B be in the curve of the hyperbola, by the last proposition. And therefore it is plain, that, proceeding on in this manner, you may find as many points as may be thought convenient, which being all joined together with an even hand will form the hyperbola required.

There are several other ways of delineating an hyperbola in plano; one way is by finding a competent number of ordinates, but none more easy and expeditious than this mechanical way: We shall therefore, for brevity's sake, pass over the rest, and leave them to the learner's practice, as being easily deduced from what has been already said.

From the comparisons which have been all along made between the hyperbola and the ellipsis, it will be easy to perceive the coherence that is between those two figures. But for the better understanding of what is meant by the center and asymptote of an hyperbola, consider *fig.* 9. where it is evident that the opposite hyperbola's will always be alike, because they will always have the same transverse diameter common to both, &c. Also that the middle point, or common center of the ellipsis, is the common center to all the four conjugal hyperbola's.

And the two diagonals of the right-angled parallelogram which circumscribes the ellipsis (or is inscribed to the four hyperbola's) being continued, will be such asymptotes to those hyperbola's.

HYPERBOLÆON, in ancient music, the upper or last tetrachord or fourth.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged, or diminished. See the article EXAGGERATION.

The word is Greek, ὑπερβολη, *superlatio*; formed of the verb ὑπερβαλλειν, *exsuperare*, to exceed, surpass by far.

The character of an hyperbole is to exaggerate or extenuate the idea of the things spoken of beyond the bounds of truth, or even probability. As, he ran swifter than the wind: he went slower than a tortoise, &c. Hyperboles, says Seneca, lie without deceiving; they lead the mind to truth by fictions; they convey the sentiment intended, though by expressing it in terms which render it incredible. The hyperbole promises too much, in order to make you conceive enough.

Aristotle observes, that hyperboles are the favourite figures of young authors, who love excess and exaggeration; but that philosophers should not use them without a great deal of reserve. The pitch to which an hyperbole may be carried, is a point of great delicacy. To carry it too far, is to destroy it: it is of the nature of a bowstring, which by immoderate tension, slackens; and frequently has an effect quite contrary to that intended.

Those hyperboles are best, which are latent, and are not taken for hyperboles. For this reason they should scarce ever be used but in a passion, and in the middle of some important incident: such is the hyperbole of Herodotus, speaking of the Lacedæmonians, who fought at Thermopylæ: "They defended themselves for some time with the arms that were left them, and at last with their hands and teeth; till the Barbarians, continually shooting, buried them as it were, with their arrows."

Now what likelihood is there, that naked men should defend themselves with their hands and teeth against armed men; and that so many persons should be buried under their enemies arrows? Yet does there appear some probability in the thing, by reason it is not sought for the sake of the figure, but the hyperbole seems to arise out of the subject itself. Of the like kind is that passage in a comic poet mentioned by Longinus; "He had lands in the country no longer than a Lacedæmonian epistle."

HYPERBOLICAL *Cylindroid*, in geometry, a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions, N°. 48.

There are two opposite hyperbolas joined by the transverse axis; and through the center there is a right line drawn at right angles to that axis; then the hyperbolas are supposed to revolve, by which revolution a body will be generated, which he calls an hyperbolical cylindroid; and whose basis, and all sections parallel to them, will be circles. And in N°. 53, of the Transactions, he applies it to the grinding of hyperbolical glasses; and he says they must be either formed this way, or not at all.

HYPERBOLIC *Space* is the convex area or space contained between the curve of the hyperbola and the external ordinate. If $CL = b$ (plate LXXV. *fig.* 10.) $LQ = x$, $CF = a$, and $QP = y$; then by the nature of the hyperbola $aa = by + xy$ and $y = \frac{aa}{b+x}$, whence $y\dot{x} = \frac{aa\dot{x}}{b+x}$; wherein, if $a = b$, we shall have $\frac{a\dot{x}}{a+x}$ for the fluxion of the indefinite area LQPF, whose fluent $x - \frac{x^2}{2a^2} + \frac{x^3}{3a^3} - \frac{x^4}{4a^4}$ &c. will when $a = 1$ become $x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \frac{1}{5}x^5$, &c. for the area required.

Any hyperbolical space GEHG (*fig.* 11.) is to any other hyperbolic figure of the same height $gEbg$ (whose latus rectum and transverse diameter, as in the circle, are equal; and also both equal to DE the transverse diameter of the former space) as the conjugate axis AB is to the transverse axis DE. The area of any asymptotical hyperbolic space DEVB (*fig.* 12.) may be found by means of the logarithms. Take the differences of the logarithms of the numbers expressing the ratio of DE to BV, and find the logarithm of that difference, to which add the constant logarithm 0,3622156887; and the sum will be the logarithm of a number expressing the space EDVB, in such parts as the oblong CD is 10000000000.

HYPERBOLIC *Conoid* is a solid generated by the entire rotation of the hyperbolic space FAG (*fig.* 13.) about the part AF of the transverse axis.

If AC be the semi-transverse axis, it will be as $2AC + AF$ is to $3AC + AF$, so is the cone whose base is the circle

circle described by FG, and altitude AF, to the conoid described as before. To prove this, let AC=a, AF=x, FG=y, the latus rectum=b, and ,7854=p; then $y^2 = bx + \frac{bxx}{2a}$; therefore $\frac{4pbx^2}{2} + \frac{2pbx^3}{3a}$ will express the solidity of the conoid, and $\frac{4pbx^2}{3} + \frac{2pbx^3}{3a}$ that of a cone, whose base is the circle described by FG and altitude AF; but these are manifestly in the proportion of $3a+x$ to $2a+x$, or of 3AC+AF to 2AC+AF.

HYPERBOLICUM ACUTUM is a solid made by the revolution of the infinite area of the space contained between the curve and the asymptote, in the Appollonian hyperbola, turning round that asymptote. This produces a solid or body infinitely long; and yet, as Torricellius plainly demonstrates (who gave it this name), it is equal to a finite magnitude.

HYPERBOLIC *Spindle*. See *Hyperbolic* SPINDLE.

HYPERBOLIFORM FIGURES, are such curves as approach, in their properties, to the nature of the hyperbola, called also hyperboloides.

HYPERCATALECTIC, in the Greek and Latin poetry, is applied to a verse, which has one or two syllables too much, or beyond the regular and just measure: as,

Musæ sorores sunt Minervæ. Also,
Musæ sorores Palladis lugent.

The Greek and Latin verses are distinguished, with respect to their measure, into four kinds, acatalectic, catalectic, brachycatalectic, and hypercatalectic. See ACATALECTIC, &c.

The hypercatalectic is also called the hyperpreter.

HYPERDULIA, in the church of Rome, a species of worship paid to the Holy Virgin; being greater than the dulia, or worship paid to the saints, but less than the latria or supreme worship paid to the Deity. See ADORATION and WORSHIP.

HYPERICUM, St. John's-wort, in botany, a plant with slender round stalks, which have two fine ridges, or sharp edgings, opposite, alternately, from joint to joint; small oblong obtuse leaves, set in pairs without pedicles; and numerous gold-coloured pentapetalous flowers on the tops of the branches, followed by little rough blackish husks, each of which is divided into three cells full of minute seeds. It is perennial, grows wild in woods and uncultivated places, and flowers in June.

This plant has been recommended as a medicine of peculiar efficacy in hysterical, hypochondriacal, and melancholic disorders, and alienations of mind; from its supposed virtue in which cases, it received the name of *fuga dæmonum*. It promises to be of some use as a mild detergent and corroborant, discovering to the senses a resinous, bitterish, balsamic impregnation. The leaves, viewed against the light, exhibit numerous transparent points, which are found to be little vesicles full of essential oil: in distillation with water, the oil separates and rises to the surface, approaching in some degree to that of turpentine. About the edges of the flower are observed black points, and on the seed-vessels small tubercles, which appear to be similar oily vesicles: the tops, when the seeds are formed, have the strongest terebinthinate smell, and yield in distillation the greatest quantity of oil. The flowery tops give a deep yellowish red tincture to rectified spirit, and a paler red to expressed oils: a tincture of the flowers in oil of olive, made by macerating four ounces of the full blown flowers, fresh gathered and freed from the cups, in a quart of oil, till the oil is sufficiently coloured, is kept for external purposes in the shops.

HYPERMETER, in the ancient poetry, the same with hypercatalectic. See the article HYPERCATALECTIC.

HYPERSARCOSIS, in medicine and surgery, an excess of flesh, or rather a fleshy excrescence, such as those generally arising upon the lips of wounds, &c. See WOUND and EXCRESCENCE.

HYPERTHYRON, in the ancient architecture, a sort of table used after the manner of a frieze, over the jaumbs of Doric doors and gates, and the lentils of windows. It lies immediately under the corona, and our workmen usually call it the king-piece.

HYPHEN, an accent, or character, in grammar, implying that two words are to be joined, or connected into one compound word, and marked thus -, as preestablished, five-leaved, &c.

Hyphens also serve to connect the syllables of such words as are divided by the end of the line.

HYPNOTIC, in the materia medica, such medicines as any way produce sleep, whether called narcotics, hypnotics, opiates, or soporifics.

Authors are of various opinions in regard ro the manner wherein hypnotics operate. See the article NARCOTICS.

HYPOCAUSTUM, among the Greeks and Romans, a subterraneous place, wherein was a furnace, to heat the baths. See BATHS.

Another kind of hypocaustum was a kind of kiln, to heat their winter parlours.

Among the moderns, it is that place where the fire is kept, that warms a stove or hot-house.

HYPOCHONDRIA, in anatomy, that part of the body on both sides, which lies under the spurious ribs, and is extended to the ilia; comprehending not only the muscles, but the internal viscera.

HYPOCHONDRIAC *Affection, Passion, or Disease, Morbus Hypochondriacus*, vulgarly called the spleen, vapours, &c. in medicine, a disorder that principally exerts its tyranny under the ensiform cartilage and spurious ribs, in the region of the hypochondria.

The hypochondriacal disease chiefly affects the abdominal viscera, viz. the stomach and intestines, the liver, spleen, pancreas, and mesentery, according to the peculiar nature of each of them. The stomach is disordered with frequent ructus's and flatulencies, the signs of crudities. The liver is swelled with thick viscid bile, obstructing its ducts. When the spleen is affected, the function of which seems to be, to convey a very fluid blood through its arteries, partly into its own cells, partly into the splenic vein, for the uses of the liver, this blood grows so thick as almost to stagnate in that vein, whereby this soft organ is tumefied and distended. If the pancreas be affected, the glands which secrete the pancreatic juice, grow scirrhous in some degree, and perform their office too sparingly: hence the bile, which mixes with it in the intestines, is not sufficiently diluted; and the chyle being too thick, passes with difficulty through the lacteals, and in some measure stagnates in its passage. When the omentum is disordered in this disease, the thin subtile oil, which is collected in its cellules, in order to be conveyed to the liver, and there to be mixed with the blood brought thither from the spleen, passes in lesser quantities than usual, whereby the blood in the vena portarum is not rendered thin and fluid enough. In fine, the consequence of the mesentery being affected is, that through the obstruction of its glands, and subsequent deficiency of the lymph, which they ought to secrete for the dilution of the chyle; this liquor becomes too thick, and less proper for nutrition. Hence, it manifestly appears, that in this disease the blood and humours grow thick and sluggish, and are rendered unfit for their respective motions, and the uses of life.

This disease, so various in appearance, is chiefly owing to two causes, rest of body, and agitation of mind: by the former the humors are rendered too sluggish in their motions; and by the latter, the blood at one time almost stagnates, and at another is driven on with excessive vehemence: and health must suffer in both cases.

This theory plainly points out the cure, which consists in purging off and correcting the humors. Yet the disease does not require strong cathartics; it is much safer to trust to the milder sort, such especially as attenuate the humors, and work by stool and urine at the same time. Of this kind are the deobstruent pills, aloetics blended with saponaceous medicines, rhubarb, Glauber's salt, and the like.

The lentor and thickness of the humors are most conveniently removed by chalybeates, bitters, and aromatics, especially in tinctures. And natural chalybeate waters are the most efficacious of all steel medicines.

In fine, all ſorts of bodily exerciſe are neceſſary; and in particular it will be of great ſervice to play at bowls or tennis, or toſs the arms briſkly to and fro with bad weights graſped in the hands; but nothing is better than riding daily on horſeback. *Mead's Monita & Præcepta.*

HYPOCISTIS, in pharmacy, an inſpiſſated juice, much reſembling the true Egyptian acacia. We meet with it in moderately large, flat maſſes. It is conſiderably hard and heavy, of a fine ſhining black colour like that of liquorice juice, when freſh broken, and of a duſkier black on the ſurface. It is brought to us from the Levant, and from ſome parts of Europe. The French make a good deal of it from the plants of their own growth, and ſometimes ſupply other places with it.

The plant from which it is produced is one of the dodecandria monogynia of Linnæus, and one of the tetrapetalæ vaſculiferæ of Ray. It grows up from the roots of ſeveral ſpecies of the ciſtus, in the manner of the orobancha or broom rape with us, and is deſcribed by all the botanical writers under the name of hypociſtis. It grows to four or five inches in height. Its ſtem is thick and fleſhy, not eaſily broken, and ſometimes of a whitiſh, ſometimes of a purpliſh, and ſometimes of a yellowiſh colour. The ſtalk is of an extremely auſtere and aſtringent taſte, with ſome degree of bitterneſs; towards the top it carries a great number of flowers interſperſed with leaves of the ſame ſquanomous kind with thoſe upon the ſtalks. The plant is eaſily ſeparated from the roots of the ciſtus to which it grows, and leaves, in the place whence it was ſeparated, a little ſmooth cavity in the ſurface without any veſtige of fibres.

This plant is very common in the iſland of Crete, and a conſiderable quantity of the inſpiſſated juice is prepared there in the ſame manner. They gather the fruits, while unripe, and expreſs the juice, which they evaporate over a very gentle fire to the conſiſtence of an extract, and then form into cakes, and expoſe to the ſun to dry.

Hypociſt is an aſtringent, and that of conſiderable power; it is good againſt diarrhœas and hæmorrhages of all kinds, and may be uſed in repellent gargariſms in the manner of the acacia; but is very rarely met with genuine in our ſhops; the German acacia being uſually ſold under its name.

HYPOGASTRIC, an appellation given to the internal branch of the iliac artery. See the articles ARTERY and ILIAC.

HYPOGASTRIC VEINS ariſe on each ſide from the iliacs, and ſend out branches to the rectum. See the article VEIN.

HYPOGASTRIUM, in anatomy, the lower part of the abdomen. See ABDOMEN.

HYPOMOCHLION, in mechanics, the ſame with fulcrum. See FULCRUM.

HYPOPYON, in medicine, a collection of purulent matter, immediately under the cornea, near the aqueous humour.

The word is Greek, and compounded of ὑπο, under, and πυον, purulent matter.

This diſorder proceeds from an extravaſation of blood, inflammation, external injuries of the eye, &c.

The principal methods of cure are three: the firſt and mildeſt is the uſe of reſolvent medicines, externally applied; to theſe may be added bleeding and purging: but when the pains and other ſymptoms increaſe, an operation is abſolutely neceſſary.

Heiſter, before he treats of the operation, deſcribes a method uſed by one Juſtus, a celebrated oculiſt in Galen's time; which was, after placing the patient conveniently before him, to lay hold of his head with both hands and ſhake it very aſſiduouſly about, till the matter diſappeared, being thereby undoubtedly thrown down behind the uvea. This, Heiſter's own experience confirmed him in: only he would have the patient's head or whole body diſpoſed in a ſupine poſture, and the eye preſſed gently with the fingers to looſen the matter.

But if this proves unſucceſsful, the patient being ſeated as in the couching for a cataract, an inciſion is made with a lancet, through the cornea, below the pupil, and about the ſpace of a line from the white of the eye, and that large enough to diſcharge the matter and aqueous humour; preſſing the eye gently by the fingers, and taking care leſt you wound the uvea: then a compreſs, moiſtened with a proper collyrium, is to be applied every third or fourth hour to the eye. If the matter be too thick to be diſcharged, the needle, which is alſo employed for making ſetons, is to be uſed. The inſtruments ſhould be wrapped up, ſo that only the point be bare. In this caſe, St. Yves adviſes to introduce a ſmall probe, or inject ſome cold water with a ſyringe, and continue this till the whole pus be diſſipated, after which the wound may be healed.

HYPORCHEMA, in the Greek poetry, a poem, conſiſting of divers kinds of verſe, and of different lengths; but always full of ſhort, or pyrrhichic feet.

HYPOSTASIS, among divines, ſignifies a perſon, or ſubſtance; chiefly uſed in ſpeaking of the perſons of the Trinity. See the article TRINITY.

HYPOSTASIS, in medicine, denotes the ſediment of urine.

HYPOTHECA, in the civil law, the ſame with mortgage in the common law. See the article MORTGAGE.

HYPOTHENAR, in anatomy, the abductor muſcle of the little finger. See the article ABDUCTOR.

HYPOTHENUSE, or HYPOTENUSE, in geometry, the longeſt ſide of a right-angled triangle, which ſubtends the right angle. Thus in the right-angled triangle ABC (plate LXXIV. *fig.* 14.) AC is the hypothenuſe.

The word is Greek, and derived from ὑπο, under, and τεινω, to extend.

The 47th prop. of Euclid's firſt book demonſtrates that, in every rectilinear right-angled triangle, the ſquare of the hypothenuſe is equal to the ſquares of both the other ſides. It is particularly called the Pythagorean problem, from its invention by Pythagoras, who is ſaid to have ſacrificed a whole hecatomb to the muſes, in gratitude for their aſſiſting him in the diſcovery.

HYPOTHESIS, in logic, a propoſition, or principle, which is taken for granted, in order to draw concluſions therefrom, for the proof of ſome point in queſtion.

The word is Greek, and compounded of ὑπο, under, and θεσις, a theſis, or poſition, which is derived from τιθημι, to place or put.

HYPOTHESIS, in phyſics, &c. an imaginary ſyſtem laid down to account for ſome phænomenon of nature.

Whatever is not derived from phænomena, ſays Sir Iſaac Newton, is an hypotheſis; and no hypotheſes of any kind are to be admitted in experimental philoſophy.

HYPOTHESIS, in aſtronomy, is more particularly applied to the ſeveral ſyſtems of the heavens, as different aſtronomers have ſuppoſed the arrangement and motion of the heavenly bodies. The principal of theſe are the Ptolemaic, Copernican, and Tychonic ſyſtems.

HYPOTRACHELION, in architecture, denotes a little frieze in the Tuſcan and Doric capitals, between the aſtragal and annulets, called likewiſe colerin, gorgerin, &c. By ſome it is applied to the neck of any column, or that part of the capital below the aſtragal.

HYPOTYPOSIS, in rhetoric, ſignifies a lively deſcription.

HYPOZOMA, in anatomy, a membrane that ſeparates two cavities: ſuch is the diaphragm.

HYPSILOIDES, in anatomy, the ſame with the os hyoides. See the article HYOIDES.

HYSSOP, in botany, a low ſhrubby medicinal plant, with brittle branchy ſtalks, ſquare when young, and round when they grow woody; oblong narrow green leaves ſet in pairs; and looſe ſpikes of labiated blue flowers, whoſe upper lip is cloven and turned upwards, ſtanding in rows, towards the tops of the ſtalks, all on one ſide. It is perennial, cultivated in our gardens, and flowers in July and Auguſt.

The whole plant has an acrid taſte, and a very ſtrong ſmell: it is attenuant and diſcutient. It is greatly recommended in diſorders of the lungs, when they are loaded with a foul and thick matter. It alſo ſtrengthens the ſtomach, and aſſiſts digeſtion; it promotes expectoration by its acrimony, and by its power of attenuating the viſcous matter in the lungs, and is therefore good in

moiſt aſthmas: its good effects in the ſtomach are of the ſame kind, depending on its attenuating and abſterging the viſcous phlegm lodged there, and impeding in it the diſcharge of its proper functions. It is alſo good in diſeaſes of the head; it is beſt taken in infuſion in the manner of tea, not made ſo ſtrong as to be diſagreeable to the palate, and often repeated. The diſtilled water, by ſome made choice of as a baſis for pectoral mixtures and julaps, does not appear ſuperior or equal to the infuſion.

Externally, hyſſop is greatly recommended in bruiſes; the blackneſs ſettling under the eyes from blows is carried off very readily by a cataplaſm of the leaves, or only a little bundle of them ſewed up in a linen rag, and applied to the part: and Ray gives us an account from Mr. Boyle, of a violent contuſion of the thigh, from the kick of a horſe, very happily cured by this herb, boiled as a cataplaſm; he tells us, the violent pain was almoſt inſtantly removed, and the very mark and blackneſs taken off in a few hours.

HYSTERICAL *Diſeaſe*, HYSTERIC *Affection*, or *Paſſion*, in medicine, a diſeaſe in women, likewiſe called a ſuffocation of the uterus, or fits of the mother.

There is no diſeaſe ſo vexatious to women as that called hyſterical; and although it may not be attended with great danger, yet it is frequently very terrifying: and it alſo ſometimes deprives them of their ſenſes as effectually, as if they had been ſeized with an epileptic fit.

When a woman has fallen into an hyſterical fit, bloodletting will be of uſe, if ſhe has ſtrength to bear it; if not, cupping-glaſſes are to be applied to her groins or hips: but if ſhe continues long in it, put the ſnuff of a candle, or ſome other thing of a fœtid ſmell, to her noſtrils, in order to rouſe her. In the mean time her thighs and legs ought to be rubbed.

When ſhe is recovered from the fit, proper means muſt be uſed to prevent a relapſe. If ſhe be liable to obſtructions, and not regular, the menſtrual diſcharges are to be promoted. The ſtrong ſmelling gums and ſteel medicines are very ſerviceable, and it is very beneficial to uſe exerciſe. But the diſturbances of the mind generally require proper remedies. *Mead.*

HYSTERIC COLIC, a common ſymptom of the hyſteric paſſion, attended with a moſt violent pain about the pit of the ſtomach; as alſo with a vomiting of a greeniſh humour, and great ſinking of the ſpirits. After a day or two the pain goes off, but upon the ſlighteſt motion or perturbation of the mind it ſoon returns again.

Neither bleeding nor cathartics have any place in the cure. According to Sydenham, it will be proper firſt to adviſe the patient to drink upwards of a gallon of poſſet-drink, to clear the ſtomach of its impurities, by throwing it up again, that the paregoric may not be hindered; afterwards give twenty-five drops of the Thebaic tincture, in an ounce of the ſpirit of cinnamon-water. The laſt is to be repeated, at due intervals, till the ſymptoms diſappear; that is, the effect of one doſe muſt be known before another is given; yet ſometimes in plethoric bodies, if the ſtrength will permit, it is better to prepare the way by bleeding and purging, or both, for an anodyne.

But if the hyſteric colic comes on by fits, the following may be uſed in the intervals, or when the fit is off: take large doſes of the balſam of Peru, that is, twenty, thirty, or forty drops, in a ſpoonful of the fineſt and whiteſt ſugar: this may be taken twice or thrice in a day.

HYSTERON PROTERON, in grammar and rhetoric, a ſpecies of the hyperbaton, wherein the proper order of conſtruction is ſo inverted, as that the part of any ſentence which ſhould naturally come firſt is placed laſt, as in this of Terence, *Valet & vivit*, for *Vivit & valet*.

HYSTEROTOMIA, υστεροτομια, in anatomy, an anatomical diſſection of the uterus or womb. See the article UTERUS.

HYSTEROTOMOTOCY, υστεροτομοτοκια, among chirurgical writers, the ſame with the Cæſarian ſection. See CÆSARIAN *Section*.

J A C

I Is the third vowel and ninth letter of the Engliſh alphabet: it is alſo a conſonant, and accordingly has two forms. When a conſonant, it is lengthened downwards, thus J, and pronounced not much unlike the ſoft G before *e*, as in geſture.

The letter I was derived from the old Hebrew *Jod*, and is ſounded by throwing the breath ſuddenly againſt the palate with a ſmall hollowing of the tongue, and the ſame opening of the lips and teeth nearly as in pronouncing A and E.

The Greeks had no J conſonant, and therefore made uſe of the I vowel inſtead of it, as ΙΗΣΟΥΣ. The Engliſh and French have two kinds of J conſonant; the firſt has a ſnuffling kind of ſound, and ſerves to modify that of the following vowels, as in *Jew*, *jolly*, &c. The latter is pronounced like the Hebrew *Jod*, which is ſounded as the conſonant *y*, as we find it ſtill among the Germans, &c. Of this we have ſome inſtances in words which are indifferently written with a *y* or *i* before a vowel; as *voiage*, *voyage*, &c.

The pronunciation of the I vowel is obſerved to be much the ſame in all nations in Europe in the Latin word *inimici*. To denote the quantity of this vowel, though it was not marked to ſhew that it was long, yet it was made bigger than the reſt, as *ÆdIIis*, *PIſo*, &c. This *i* long was pronounced like *ei*, as *divei* for *divi*, &c. Lipſius ſays that *i* was double, when it was to be ſounded long, as *dii*, *diis*, &c.

The ancients ſometimes changed *i* into *u*, as *decumus* for *decimus*, *maxumus* for *maximus*, &c. According to Plato, the vowel *i* is proper to expreſs delicate but humble things, as in this verſe in Virgil, which abounds in *i*'s, and is generally admired.

Accipiunt inimicum imbrem, rimiſque fatiſcunt.

J, in abbreviations and cyphers, ſtands for Jeſus.

I was uſed by the ancients as a numeral, denoting 100, according to this verſe.

I. c. *Compar erit, et centum ſignificabit.*

The Greek *Iota*, and the Hebrew *Jod*, ſtand but for ten.

JACENT, a term applied by Helmont to nature, when a diſeaſe is riſen to a head, and the morbific matter ſtrives to ſuppreſs the vital flame.

JACK, in mechanics, a portable machine for raiſing great weights.

In order to explain the operation of this machine, we have given perſpective views of its ſeveral parts on plate LXXIV. *fig.* 15, 16, 17, 18, where *fig.* 15. is the whole machine; *fig.* 16, ſhews the rack, and the pinion which carries it; *fig.* 17, diſplays the whole machinery; and *fig.* 18, the rack, ſeparately. The ſame letters refer to the ſame parts in all the four figures.

A, is a ſtrong caſe of wood, firmly bound with iron.

B, the open part of the caſe in which the rack moves.

C, the bottom claw of the jack, intended for raiſing weights very near the ground.

D, the rack, ſeparated from the other parts of the machinery.

J A C

E, the upper claw, or fork, of the jack.

F, a pinion of four leaves, that moves the rack D.

G, the winch or crank of the handle.

H, a hook to prevent the weight, when raiſed to a ſufficient height, from falling down again, by putting the curved part of the hook round the handle.

I, a large wheel, with ſixteen teeth.

K, a pinion of four leaves, that moves the large wheel I.

The power of this machine is very eaſily calculated in the following manner:

Suppoſe the winch or crank G, to be four times as long as the radius of the pinion K, then will the power of the machine in this part be as 4 to 1. But the pinion K has only four leaves, and the wheel I ſixteen teeth; therefore the power of the machine in this part is alſo as 4 to 1. Conſequently $4\times4=16$, is the power of both theſe parts conjointly. And as the wheel I has ſixteen teeth, and the pinion T, that moves the rack, only four leaves, the power of the machine in this part is alſo as 4 to 1. Conſequently the whole power of the machine is as 64 to 1: for $4\times4\times4=64$. If therefore we ſuppoſe a man can work at the handle with a force of thirty pounds, he will be able to raiſe a weight of one thouſand nine hundred and twenty pounds, ſuppoſing the machine to have no friction.

Kitchen JACK, a compound engine, where the weight is the power applied to overcome the friction of the parts, and the weight with which the ſpit is charged; and a ſteady and uniform motion is obtained by means of the fly. See the article FLY.

Smoak JACK. See SMOAK-JACK.

JACK-DAW, in ornithology, a ſpecies of corvus, with a black and grey head, a browniſh black body, and the wings and tail black.

It is one of the ſmalleſt of the crow-kind, but an erect and well-ſhaped bird.

JACKALL, in zoology, an animal of the dog-kind, with a ſlender ſnout.

It is a very beautiful creature, and ſo like a dog, as to be miſtaken at firſt ſight for ſome mungrel breed of that animal.

Its ſize is that of a ſmall hound; and, in the Eaſt, where it is a native, there are vaſt packs of them, often more than two hundred in a company, which hunt animals they would never dare to attack ſingle. It is not impoſſible that lions and other beaſts of prey may be alarmed by the cries of theſe animals in their chace, and fall in and rob them of their prey; but the general opinion of their attendance on the lion, is fabulous.

JACOBINE, or JACK, in ornithology, a very ſmall ſort of pigeon, with a range of feathers inverted quite over the hinder part of the head; bearing ſome reſemblance to a friar's hood, whence the name.

JACOBINE MONKS, the ſame with the Dominicans. See DOMINICANS.

JACOBITES, a term of reproach beſtowed on the perſons, who, vindicating the doctrines of paſſive obedience and non-reſiſtance with reſpect to the arbitrary pro-

proceedings of princes, diſallow of the late Revolution, and aſſert the ſuppoſed rights, and adhere to the intereſts of the late abdicated king James and his family.

JACOBITES, in church-hiſtory, a ſect of chriſtians in Syria and Meſopotamia; ſo called either from Jacob, a Syrian, who lived in the reign of the emperor Mauricius; or from one Jacob, a monk, who flouriſhed in the year 550.

JACOB's-STAFF, a mathematical inſtrument, otherwiſe called fore-ſtaff. See FORE-STAFF.

JADE-STONE, the name given to a hard greyiſh-green ſpecies of jaſper, of which the Turks generally make the handles of the ſabres of great people. See the article JASPER.

JALAP, in botany, a plant with thick, fleſhy raddiſh-like roots; jointed ſtalks and branches; acuminated ſomewhat oval leaves ſet in pairs; and elegant, numerous, monopetalous, funnel ſhaped flowers, purple, yellow, white, or diverſly variegated, ſtanding in double cups, of which the innermoſt incloſes the flower and the outer ſurrounds its baſis: each flower is followed by a wrinkled, roundiſh, pentagonal, umbilicated fruit, about the ſize of a peppercorn, including a white kernel. It is perennial, a native of the Eaſt-Indies, and cultivated in our gardens. Whether the roots produced here are equivalent in virtue to thoſe which are brought from abroad, has not, Dr. Lewis obſerves, been yet experienced.

The officinal jalap roots come from the province of Xalapa in New Spain; in thin tranſverſe ſlices, ſolid, hard, weighty, of a dark greyiſh colour on the outſide or cortical part, internally of a dark greyiſh, with ſeveral black circular ſtriæ: the hardeſt, darkeſt coloured, and thoſe which have the moſt of theſe reſinous veins, are the beſt.

This root has ſcarcely any ſmell, and very little taſte upon the tongue: ſwallowed, it affects the throat with a ſlight kind of pungency and heat. Taken in doſes of a ſcruple or half a dram, it proves an effectual, and in general a ſafe purgative; very rarely occaſioning any ſevere gripes or nauſea, which too frequently accompany the other ſtrong cathartics. Some have prohibited the uſe of this cathartic to children; apparently on no very good foundation. Young children, from the laxity of their ſolids, and the ſoft lubricating quality of their food, generally bear theſe kinds of medicines better than adults; and adults of a ſpongy, lax, or weak habit, better than the rigid or robuſt. Few, if any, of the ſtrong reſinous purgatives are in either caſe more innocent than jalap.

Theſe plants are always propagated by ſeeds, which ſhould be ſown upon a moderate hot-bed in March; and when they come up, they ſhould be tranſplanted into another hot-bed, at ſix inches diſtance from each other; and when they have taken root, the glaſſes muſt be raiſed every day, that the plants may have a great deal of air, otherwiſe they are very ſubject to be drawn up tall and weak; nor can they be recovered to a ſufficient ſtrength again in a month's time, if once they are thus drawn. When the plants are grown to be a foot high, they ſhould be put into pots filled with rich light earth, which ſhould be plunged into a very moderate hot-bed, to facilitate their taking root: and in removing them, you muſt be very careful to perſerve as much earth to their roots as you can; for their roots have but few fibres to retain it in a ball, as many other plants will do; and it ſometimes happens, when the root is left bare, it ſeldom takes freſh hold of the ground, at leaſt not in a conſiderable time; ſo that the plants will make but a poor figure that ſeaſon. When they are tranſplanted into the pots, and have taken root again, they ſhould be hardened to endure the open air, for they are not tender; but, on the contrary, they will not thrive well, if too much drawn or forced in the hot-bed. In the middle of May the pots may be removed into the places where they are deſigned to be continued for that ſeaſon; obſerving to ſupport the branches with a ſtrong ſtake, and to water them as often as they require it. You may alſo in May plant ſome of them into the middle of the large borders of the pleaſure-garden, doing it carefully; and obſerve to ſhade and water them until they have taken root; after which, they will require no farther care but to ſupport them from being broken down by the winds, which they are very ſubject to be, eſpecially when their heads are large.

The plants, thus raiſed, will grow to the height of three or four feet, and ſpread their branches very wide, eſpecially if the roots have room in the pots; and their flowers will begin to appear in June, and they will continue conſtantly flowering until the froſt prevents them; which, together with the great diverſity of colours in the flowers upon the ſame plant, renders them valuable to every curious perſon. The flowers of theſe plants never expand in the day time, while the ſun is hot; but in the evening, when the ſun declines, they begin to open, and continue expanded till the ſun ſhines warm upon them the next day; ſo that, when it happens to be cloudy weather, as alſo late in autumn, when the weather is cool, the flowers will remain open moſt part of the day.

As the flowers are produced ſucceſſively almoſt every day, ſo the ſeeds are in a ſhort time after ripe, and ſoon fall to the ground; ſo that, when your ſeeds begin to ripen, you muſt careſully look for them upon the ground twice a week: otherwiſe, if they lie too long upon the ground, and there ſhould fall ſome rain, they will ſprout, and be good for nothing. In ſowing theſe ſeeds, you ſhould be careful to take them from ſuch plants as produced the greateſt variety of flowers; for, if you ſave them from ſuch as produce only plain coloured flowers, the ſeeds will always produce the ſame ſort; and thoſe with yellow and red variegated flowers will conſtantly produce the ſame; theſe never varying from the red and yellow to the purple and white, though they will ſometimes degenerate into plain yellow or red flowers, as they will into plain purple or white: but they will conſtantly retain one or both of their original colours.

JAMAICA-PEPPER, *Pimienta*, or *Pimenta*, in the materia medica. See PIMIENTA.

JAMAICA-WOOD, a name ſometimes given to brazil. See the article BRAZIL.

JAMB, or JAUMB, among carpenters, an appellation given to door-poſts, as alſo to the upright poſts at the ſides of window-frames; and among bricklayers, it denotes the upright ſides of chimnies, from the hearth to the mantle-tree.

IAMBIC VERSES, are verſes in the Greek and Latin poetry, which are ſo called, as they wholly, or, for the moſt part, conſiſt of an iambus or iambic foot. Iambics may be conſidered either as to the diverſity, or number of their feet.

1. Pure iambics; namely, ſuch as conſiſt of nothing but iambus's, as that of Catullus, in praiſe of a yacht:

Phaſelus ille, quem videtis, hoſpites.

And Horace, in his Epod. joins theſe to hexameters:

Altera jam teritur bellis civilibus ætas,
Suis et ipſa Roma viribus ruit.

2. Thoſe ſimple iambics, which have the iambus in the even places; to wit, the ſecond, fourth, and ſixth feet; though we ſometimes find tribrachys's added to them, only that the laſt foot ſhould always be an iambus: and in the uneven places, that is, the firſt, third, and fifth, a ſpondee, anapeſte, and even a dactyle in the firſt foot, as that of Medea in Ovid:

Servare potui, perdere an poſſim rogas?

3. The free iambics, in which the laſt foot alone is an iambus, as that of Phædrus:

Amittit merito proprium, qui alienum appetit.

In comedy, the authors are leſs confined, as we may ſee in Terence, Plautus, &c. only the ſixth foot is indiſpenſably to be an iambus.

As to the diverſity ariſing from the number of ſyllables:

1. Thoſe iambics that conſiſt of four feet are called dimeters, as

Quærunturin ſylvis aves.

2. Iambics of ſix feet are called trimeters: theſe verſes are chiefly uſed for the theatre, particularly in tragedy

and are more natural to the ſtage than thoſe of ten or twelve feet, uſed in the modern drama, in regard they approach near to proſe, and favour leſs of affection and poetry:

Dii conjugales, tuque genialis tori.
Lucina, cuſtos, &c.

3. Iambics with eight feet are called tetfameters, and are only uſed in comedy, as that of Terence,

Pecuniam in loco negligere maximum interdum eſt lucrum.

Some add to theſe an iambic monometer, conſiſting of two feet, as,

Virtus beat.

They are denominated monometer, dimeter, trimeter, and tetrameter, as being of one, two, three, and four meaſures; each meaſure conſiſting of two feet; for the Greeks meaſured their verſes two feet by two feet, by bipodys or epitrites; namely, by joining the iambus and ſpondee together.

Thoſe iambics already mentioned are perfect, having their proper number of feet, without any redundant or deficient. The imperfect iambics are,

1. The catalectic, which want a ſyllable, as,

Muſæ Jovem canebant.

2. The brachycatalectic, ſuch as have either a foot or a ſyllable too much, as,

Muſæ ſorores ſunt Minervæ.
Muſæ ſorores Palladis lugent.

Many of the church hymns and anthems are dimeter iambics; that is, conſiſting of four feet.

IAMBUS, in ancient poetry, a ſimple foot conſiſting of a ſhort and a long ſyllable, as *pios*. See FOOT.

JAMES, or *Knights of St.* JAMES, a military order in Spain, firſt inſtituted about the year 1170, by Ferdinand II. king of Leon and Galicia. The greateſt dignity belonging to this order is grand maſter, which has been united to the crown of Spain. The knights are obliged to make proof of their deſcent from families that have been noble for four generations, on both ſides: they muſt alſo make it appear that their ſaid anceſtors have neither been Jews, Saracens, nor heretics; nor have ever been called into queſtion by the inquiſition. The novices are obliged to ſerve ſix months in the galleys, and to live a month in a monaſtery; they obſerve the rule of St. Auſtin, making no vows but of poverty, obedience, and conjugal fidelity.

St. JAMES'S-DAY, a feſtival of the Chriſtian church obſerved on the 25th of July, in memory of St. James the greater, ſon of Zebedee.

Epiſtle of St. JAMES, a canonical book of the New Teſtament, being the firſt of the catholic or general epiſtles; which are ſo called, as not being written to one but to ſeveral Chriſtian churches.

This general Epiſtle is addreſſed partly to the believing and partly to the infidel Jews; and is deſigned to correct the errors, ſoften the ungoverned zeal, and reform the indecent behaviour of the latter; and to comfort the former under the great hardſhips they then did, or ſhortly were to ſuffer, for the ſake of Chriſtianity.

JANIZARIES, an order of the Turkiſh infantry, reputed the grand ſignior's guards, and the main ſtrength of the Ottoman army.

JANSENISTS, in church-hiſtory, a ſect of the Roman-catholics in France, who follow the opinions of Janſenius, biſhop of Ypres, and doctor of divinity of the univerſities of Louvain and Douay, in relation to grace and predeſtination.

In the year 1640, the two univerſities juſt mentioned, and particularly father Molina and father Leonard Celſus, thought fit to condemn the opinions of the Jeſuits on grace and free-will. This having ſet the controverſy on foot, Janſenius oppoſed to the doctrine of the Jeſuits the ſentiments of St. Auguſtine, and wrote a treatiſe on grace, which he entitled Auguſtinus. This treatiſe was attacked by the Jeſuits, who accuſed Janſenius of maintaining dangerous and heretical opinions; and afterwards, in 1642, obtained of pope Urban VIII. a formal condemnation of the treatiſe wrote by Janſenius: when the partiſans of Janſenius gave out that this bull was ſpurious, and compoſed by a perſon entirely devoted to the jeſuits. After the death of Urban VIII. the affair of Janſeniſm began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace; and what occaſioned ſome mirth, was the titles which each party gave to their writings: one writer publiſhed, The Torch of St. Auguſtin, another found Snuffers for St. Auguſtin's Torch, and father Veron formed a Gag for the Janſeniſts, &c. In the year 1650, ſixty-eight biſhops of France ſubſcribed a letter to pope Innocent X. to obtain an enquiry into, and condemnation of the five following propoſitions, extracted from Janſenius's Auguſtinus: I. Some of God's commandments are impoſſible to be obſerved by the righteous, even though they endeavour, with all their power, to accompliſh them. II. In the ſtate of corrupted nature, we are incapable of reſiſting inward grace. III. Merit and demerit in a ſtate of corrupted nature, does not depend on a liberty which excludes neceſſity, but on a liberty which excludes conſtraint. IV. The Semipelagians admitted the neceſſity of an inward preventing grace for the performance of each particular act, even for the beginning of faith, but they were heretics in maintaining that this grace was of ſuch a nature, that the will of man was able either to reſiſt or obey it. V. It is Semipelagianiſm to ſay that Jeſus Chriſt died, or ſhed his blood, for all mankind in general.

In the year 1652, the pope appointed a congregation for examining into the diſpute in relation to grace. In this congregation Janſenius was condemned, and the bull of condemnation, publiſhed in May 1653, filled all the pulpits in Paris with violent outeries and alarms againſt the hereſy of the Janſeniſts. In the year 1656, pope Alexander VII. iſſued out another bull, in which he condemned the five propoſitions of Janſenius. However, the Janſeniſts affirm, that theſe propoſitions are not to be found in his book; but that ſome of his enemies having cauſed them to be printed on a ſheet, inſerted them in the book, and thereby deceived the pope. At laſt Clement XI. put an end to the diſpute by his conſtitution of July 17, 1705; in which, after having recited the conſtitutions of his predeceſſors in relation to this affair, he declares, "That in order to pay a proper obedience to the papal conſtitutions concerning the preſent queſtion, it is neceſſary to receive them with a reſpectful ſilence." The clergy of Paris, the ſame year, approved and accepted this bull, and none dared to oppoſe it.

This is the famous bull *Unigenitus*, ſo called from its beginning with the words *unigenitus dei filius*, &c. which has occaſioned ſo much confuſion in France.

JANUARY, the firſt month in the year, according to the preſent computation. It was introduced by Numa into the calendar, and placed at the winter ſolſtice, where March was before, which Romulus had placed at the vernal equinox.

The word is derived from Janus, to whom the Romans on the firſt of this month offered ſolemn ſacrifices.

JAPAN EARTH, in the materia medica. See the article TERRA *Japonica*.

JAPANNING, the art of varniſhing and drawing figures on wood, in the ſame manner as is done by the natives of Japan in the Eaſt-Indies.

The ſubſtances which admit of being japanned are almoſt every kind that are dry and rigid, or not too flexible: as wood, metals, leather, and paper prepared.

Wood and metals do not require any other preparation, but to have their ſurface perfectly even and clean: but leather ſhould be ſecurely ſtrained either on frames, or on boards; as its bending or forming folds would otherwiſe crack and force off the coats of varniſh; and paper ſhould be treated in the ſame manner; and have a previous ſtrong coat of ſome kind of ſize; but it is rarely made the ſubject of japanning till it is converted into papier machè, or wrought by other means into ſuch form, that its original ſtate, particularly with reſpect to flexibility, is loſt.

One principal variation from the method formerly uſed in japanning is, the uſing or omitting any priming or undercoat on the work to be japanned. In the older practice, ſuch priming was always uſed; and is at preſent re-

ed in the French manner of japanning coaches and snuff-boxes of the papier machè: but in the Birmingham manufacture here, it has been always rejected. The advantage of uſing ſuch priming or undercoat is, that it makes a ſaving in the quantity of varniſh uſed; becauſe the matter of which the priming is compoſed fills up the inequalities of the body to be varniſhed; and makes it eaſy, by means of rubbing and water-poliſhing, to gain an even ſurface for the varniſh: and this was therefore ſuch a convenience in the caſe of wood, as the giving a hardneſs and firmneſs to the ground was alſo in the caſe of leather, that it became an eſtabliſhed method; and is therefore retained even in the inſtance of the papier machè, by the French, who applied the received method of japanning to that kind of work on its introduction. There is nevertheleſs this inconvenience always attending the uſe of an undercoat of ſize, that the japan coats of varniſh and colour will be conſtantly liable to be cracked and peeled off, by any violence, and will not endure near ſo long as the bodies japanned in the ſame manner, but without any ſuch priming; as may be eaſily obſerved in comparing the wear of the Paris and Birmingham ſnuff-boxes; which latter, when good of their kind, never peel or crack, or ſuffer any damage, unleſs by great violence, and ſuch a continued rubbing, as waſtes away the ſubſtance of the varniſh; while the japan coats of the Pariſian crack and fly off in flakes, whenever any knock or fall, particularly near the edges, expoſes them to be injured. But the Birmingham manufacturers, who originally practiſed the japanning only on metals, to which the reaſon above given for the uſe of priming did not extend, and who took up this art of themſelves as an invention, of courſe omitted at firſt the uſe of any ſuch undercoat; and not finding it more neceſſary in the inſtance of papier machè, than on metals, continue ſtill to reject it. On which account the boxes of their manufacture are, with regard to the wear, greatly better than the French.

The laying on the colours in gum-water, inſtead of varniſh, is alſo another variation from the method of japanning formerly practiſed: but the much greater ſtrength of the work, where they are laid on in varniſh or oil, has occaſioned this way to be exploded with the greateſt reaſon in all regular manufactures: however, they who may practiſe japanning on cabinets, or other ſuch pieces as are not expoſed to much wear and violence, for their amuſement only, and conſequently may not find it worth their while to encumber themſelves with the preparations neceſſary for the other methods, may paint with water colours on an undercoat laid on the wood, or other ſubſtance of which the piece to be japanned is formed; and then finiſh with the proper coats of varniſh, according to the methods below taught: and if the colours are tempered with the ſtrongeſt iſinglaſs ſize and honey, inſtead of gum-water, and laid on very flat and even, the work will not be much inferior in appearance to that done by the other method; and will laſt as long as the old japan.

Of JAPAN *Grounds.*—The proper grounds are either ſuch as are formed by the varniſh and colour, where the whole is to remain of one ſimple colour; or by the varniſh either coloured, or without colour, on which ſome painting or other decoration is afterwards to be laid. It is neceſſary, however, before we proceed to ſpeak of the particular grounds, to ſhew the manner of laying on the priming or undercoat, where any ſuch is uſed.

This priming is of the ſame nature with that called clear-coating, or vulgarly clear-coaling, practiſed erroneouſly by the houſe-painters; and conſiſts only in laying in and drying in the moſt even manner, a compoſition of ſize and whiting, or ſometimes lime inſtead of the latter. The common ſize has been generally uſed for this purpoſe; but where the work is of a nicer kind, it is better to employ the glover's or the parchment ſize; and if a third of iſinglaſs be added, it will be ſtill better; and if not laid on too thick, much leſs liable to peel and crack. The work ſhould be prepared for this priming, by being well ſmoothed with the fiſh-ſkin, or glaſs-ſhaver; and, being made thoroughly clean, ſhould be bruſhed over once or twice with hot ſize, diluted with two thirds of water, if it be of the common ſtrength. The priming ſhould then be laid on with a bruſh as even as poſſible; and ſhould be formed of a ſize, whoſe conſiſtence is betwixt the common kind and glue, mixed with as much whiting as will give it a ſufficient body of colour to hide the ſurface of whatever it is laid upon, but not more.

If the ſurface be very clean, on which the priming is uſed, two coats of it, laid on in this manner, will be ſufficient; but if, on trial with a fine rag wet, it will not receive a proper water poliſh, on account of any inequalities not ſufficiently filled up and covered, two or more coats muſt be given it; and whether a greater or leſs number be uſed, the work ſhould be ſmoothed, after the laſt coat but one is dry, by rubbing it with the Dutch ruſhes. When the laſt coat is dry, the water poliſh ſhould be given, by paſſing over every part of it with a fine rag gently moiſtened, till the whole appear perfectly plain and even. The priming will then be completed, and the work ready to receive the painting or coloured varniſh; the reſt of the proceedings being the ſame in this caſe as where no priming is uſed.

When wood or leather is to be japanned, and no priming is uſed, the beſt preparation is to lay two or three coats of coarſe varniſh compoſed in the following manner:

"Take of rectified ſpirit of wine one pint, and of coarſe ſeed-lac and reſin each two ounces. Diſſolve the ſeed-lac and reſin in the ſpirit; and then ſtrain off the varniſh."

This varniſh, as well as all others formed of ſpirit of wine, muſt be laid on in a warm place; and, if it can be conveniently managed, the piece of work to be varniſhed ſhould be made warm likewiſe: and for the ſame reaſon all dampneſs ſhould be avoided; for either cold or moiſture chill this kind of varniſh, and prevent its taking proper hold of the ſubſtance on which it is laid.

When the work is ſo prepared, or by the priming with the compoſition of ſize and whiting above deſcribed, the proper japan ground muſt be laid on; which is much the beſt formed of ſhell-lac varniſh, and the colour deſired, if white be not in queſtion, which demands a peculiar treatment, or great brightneſs be not required; when alſo other means muſt be purſued.

The colours uſed with the ſhell-lac varniſh may be any pigments whatever which give the teint of the ground deſired; and they may be mixed together to form browns or any compound colours.

As metals never require to be undercoated with whiting, they may be treated in the ſame manner as wood or leather, when the undercoat is omitted, except in the inſtances particularly ſpoken of below.

White JAPAN *Grounds.*—The forming a ground perfectly white, and of the firſt degree of hardneſs, remains hitherto a deſideratum, or matter ſought for, in the art of japanning, as there are no ſubſtances which form a very hard varniſh, but what have too much colour not to deprave the whiteneſs, when laid on of a due thickneſs over the work.

The neareſt approach, however, to a perfect white varniſh, already known, is made by the following compoſition.

"Take flake white, or white lead, waſhed over and ground up with a ſixth of its weight of ſtarch, and then dried; and temper it, properly for ſpreading, with the maſtich varniſh prepared as under the article VARNISH.

"Lay theſe on the body to be japanned, prepared either with or without the undercoat of whiting, in the manner as above ordered; and then varniſh over it with five or ſix coats of the following varniſh.

"Provide any quantity of the beſt ſeed lac; and pick out of it all the cleareſt and whiteſt grains, reſerving the more coloured and fouler parts for the coarſe varniſhes, ſuch as that uſed for priming or preparing wood or leather. Take of this picked ſeed-lac two ounces; and of gum-animi three ounces; and diſſolve them, being previouſly reduced to a groſs powder, in about a quart of ſpirit of wine; and ſtrain off the clear varniſh."

The ſeed-lac will yet give a ſlight tinge to this compoſition; but cannot be omitted where the varniſh is wanted to be hard; though, when a ſofter will anſwer the end, the proportion may be diminiſhed; and a little crude

turpentine

turpentine added to the gum-animi to take off the bitterneſs.

A very good varniſh, free entirely from all bitterneſs, may be formed by diſſolving as much gum-animi as the oil will take, in old nut or poppy oil; which muſt be made to boil gently, when the gum is put into it. The ground of white colour itſelf may be laid on in this varniſh; and then a coat or two of it may be put over the ground; but it muſt be well diluted with oil of turpentine when it is uſed. This, though free from brittleneſs, is nevertheleſs liable to ſuffer by being indented or bruiſed by any ſlight ſtrokes; and it will not well bear any poliſh, but may be brought to a very ſmooth ſurface without, if it be judiciouſly managed in the laying it on. It is likewiſe ſomewhat tedious in drying, and will require ſome time where ſeveral coats are laid on; as the laſt ought not to contain much oil of turpentine.

Blue JAPAN *Grounds.*—Blue japan grounds may be formed of bright Pruſſian blue; or of verditer glazed over by Pruſſian blue; or of ſmalt. The colour may be beſt mixed with ſhell-lac varniſh; and brought to a poliſhing ſtate by five or ſix coats of varniſh of ſeed-lac; but the varniſh, nevertheleſs, will ſomewhat injure the colour, by giving to a true blue a caſt of green; and fouling in ſome degree a warm blue, by the yellow it contains: where, therefore, a bright blue is required, and a leſs degree of hardneſs can be diſpenſed with, the method before directed, in the caſe of white grounds, muſt be purſued.

Red JAPAN *Grounds.*—For a ſcarlet japan ground, vermilion may be uſed; but the vermilion has a glaring effect, that renders it much leſs beautiful than the crimſon produced by glazing it over with carmine or fine lake; or even with roſe pink, which has a very good effect uſed for this purpoſe. For a very bright crimſon nevertheleſs, inſtead of glazing with carmine, the Indian lake ſhould be uſed, diſſolved in the ſpirit of which the varniſh is compounded, which it readily admits of when good: and, in this caſe, inſtead of glazing with the ſhell-lac varniſh, the upper or poliſhing coats need only be uſed; as they will equally receive and convey the tinge of the Indian lake, which may be actually diſſolved by ſpirit of wine: and this will be found a much cheaper method than the uſing carmine. If, nevertheleſs, the higheſt degree of brightneſs be required, the white varniſhes muſt be uſed.

Yellow JAPAN *Grounds.*—For bright yellow grounds, the king's yellow, or the turpeth mineral, ſhould be employed, either alone or mixed with fine Dutch pink: and the effect may be ſtill more heightened by diſſolving powdered turmeric root in the ſpirit of wine of which the upper or poliſhing coat is made; which ſpirit of wine muſt be ſtrained from off the dregs, before the ſeed-lac be added to it to form the varniſh.

The ſeed-lac varniſh is not equally injurious here, and with greens, as in the caſe of other colours; becauſe being only tinged with a reddiſh yellow, it is little more than an addition to the force of the colours.

Yellow grounds may be likewiſe formed of the Dutch pink only; which, when good, will not be wanting in brightneſs, though extremely cheap.

Green JAPAN *Grounds.*—Green grounds may be produced by mixing the king's yellow and bright Pruſſian blue; or rather, the turpeth mineral and Pruſſian blue; and a cheap, but fouler kind, by verdigriſe with a little of the above mentioned yellows, or Dutch pink. But where a very bright green is wanted, the cryſtals of verdigriſe, called diſtilled verdigriſe, ſhould be employed; and to heighten the effect, they ſhould be laid on a ground of leaf gold, which renders the colour extremely brilliant and pleaſing.

They may any of them be uſed ſucceſsfully with good ſeed-lac varniſh, for the reaſon before given, but will be ſtill brighter with white varniſh.

Orange-coloured JAPAN *Grounds.*—Orange-coloured japan grounds may be formed by mixing vermilion, or red lead with king's yellow, or Dutch pink; or the orange lake, which will make a brighter orange ground than can be produced by any mixture.

Purple JAPAN *Grounds.*—Purple japan grounds may be produced by the mixture of lake, and Pruſſian blue: or a fouler kind, by vermilion and Pruſſian blue. They may be treated as the reſt, with reſpect to the varniſh.

Black JAPAN *Grounds to be produced without Heat.*—Black grounds may be formed by either ivory-black, or lamp-black: but the former is preferable, where it is perfectly good.

Theſe may be always laid on with the ſhell-lac varniſh; and have their upper or poliſhing coats of common ſeed-lac varniſh; as the tinge or foulneſs of the varniſh can be here no injury.

Common black JAPAN *Grounds on Iron or Copper, produced by means of Heat.*—For forming the common black japan grounds by means of heat, the piece of work to be japanned muſt be painted over with drying oil: and when it is of a moderate dryneſs, muſt be put into a ſtove of ſuch degree of heat, as will change the oil black, without burning it ſo as to deſtroy or weaken its tenacity. The ſtove ſhould not be too hot when the work is put into it, nor the heat increaſed too faſt; either of which errors would make it bliſter: but the ſlower the heat is augmented, and the longer it is continued, provided it be reſtrained within the due degree, the harder will be the coat of japan. This kind of varniſh requires no poliſh, having received, when properly managed, a ſufficient one from the heat.

The fine Tortoiſe-ſhell JAPAN *Ground, produced by means of Heat.*—The beſt kind of tortoiſe-ſhell ground produced by heat is not leſs valuable for its great hardneſs, and enduring to be made hotter than boiling water, without damage, than for its beautiful appearance. It is to be made by means of a varniſh, prepared in the following manner:

"Take of good linſeed oil one gallon, and of umbre half a pound: boil them together till the oil become very brown and thick: ſtrain it then through a coarſe cloth; and ſet it again to boil; in which ſtate it muſt be continued till it acquire a pitchy conſiſtence; when it will be fit for uſe."

Having prepared thus the varniſh, clean well the iron or copper-plate, or other piece which is to be japanned; and then lay vermilion tempered with ſhell-lac varniſh, or with drying oil diluted with oil of turpentine very thinly, on the places intended to imitate the more tranſparent parts of the tortoiſe-ſhell. When the vermilion is dry, bruſh over the whole with the black varniſh, tempered to a due conſiſtence with oil of turpentine; and when it is ſet and firm, put the work into a ſtove, where it may undergo a very ſtrong heat, and muſt be continued a conſiderable time; if even three weeks or a month, it will be the better.

This was given amongſt other receipts by Kunkel; but appears to have been neglected till it was revived with great ſucceſs in the Birmingham manufactures, where it was not only the ground of ſnuff-boxes, dreſſing-boxes, and other ſuch leſſer pieces, but of thoſe beautiful tea-waiters, which have been ſo juſtly eſteemed and admired in ſeveral parts of Europe where they have been ſent. This ground may be decorated with painting and gilding, in the ſame manner as any other varniſhed ſurface, which had beſt be done after the ground has been duly hardened by the hot ſtove; but it is well to give a ſecond annealing with a more gentle heat after it is finiſhed.

Method of Painting JAPAN *Work.*—Japan work ought properly to be painted with colours in varniſh; though, in order for the greater diſpatch, and, in ſome very nice works in ſmall, for the freer uſe of the pencil, the colours are ſometimes tempered in oil; which ſhould previouſly have a fourth part of its weight of gum-animi diſſolved in it; or, in default of that, of the gums ſanderac or maſtic. When the oil is thus uſed, it ſhould be well diluted with ſpirit of turpentine, that the colours may be laid more evenly and thin; by which means, fewer of the poliſhing or upper coats of varniſh become neceſſary.

In ſome inſtances, water colours are laid on grounds of gold, in the manner of other paintings, and are beſt, when ſo uſed, in their proper appearance, without any varniſh over them; and they are alſo ſometimes ſo managed as to have the effect of emboſſed work. The colours employed in this way, for painting, are beſt prepared by means of iſinglaſs ſize corrected with honey or ſugar candy.

candy. The body of which the embossed work is raised, need not, however, be tinged with the exterior colour; but may be best formed of very strong gum-water, thickened to a proper consistence by bole armoniac and whiting in equal parts; which being laid on in the proper figure, and repaired when dry, may be then painted with the proper colours tempered in the isinglass size, or in the general manner with shell-lac varnish.

Manner of Varnishing JAPAN *Work.*—The last, and finishing part of japanning, lies in the laying on and polishing the outer coats of varnish; which are necessary, as well in the pieces that have only one simple ground of colour, as with those that are painted. This is in general best done with common seed-lac varnish, except in the instances, and on those occasions where we have already shewn other methods to be more expedient: and the same reasons which decide as to the fitness or impropriety of the varnishes, with respect to the colours of the ground, hold equally well with regard to those of the painting: for where brightness is the most material point, and a tinge of yellow will injure it, seed-lac must give way to the whiter gums; but where hardness, and a greater tenacity, are most essential, it must be adhered to; and where both are so necessary, that it is proper one should give way to the other, in a certain degree reciprocally, a mixed varnish must be adopted.

This mixed varnish, as we have already observed, should be made of the picked seed-lac. The common seed-lac varnish, which is the most useful preparation of the kind hitherto invented, may be thus made.

"Take of seed-lac three ounces, and put it into water to free it from the sticks and filth that are frequently intermixed with it; and which must be done by stirring it about, and then pouring off the water, and adding fresh quantities in order to repeat the operation, till it be freed from all impurities; as it very effectually may be by this means. Dry it then, and powder it grossly, and put it, with a pint of rectified spirit of wine, into a bottle, of which it will not fill above two thirds. Shake the mixture well together; and place the bottle in a gentle heat, till the seed appear to be dissolved; the shaking being in the mean time repeated as often as may be convenient: and then pour off all which can be obtained clear by that method; and strain the remainder through a coarse cloth. The varnish thus prepared must be kept for use in a bottle well stopt."

When the spirit of wine is very strong, it will dissolve a greater proportion of the seed-lac: but this will saturate the common, which is seldom of a strength sufficient for making varnishes in perfection. As the chilling, which is the most inconvenient accident attending those of this kind, is prevented, or produced more frequently, according to the strength of the spirit; we shall therefore take this opportunity of shewing a method by which weaker rectified spirits may with great ease, at any time, be freed from the phlegm, and rendered of the first degree of strength.

"Take a pint of the common rectified spirit of wine, and put it into a bottle, of which it will not fill above three parts. Add to it half an ounce of pearl-ashes, salt of tartar, or any other alkaline salt, heated red-hot, and powdered, as well as it can be without much loss of its heat. Shake the mixture frequently for the space of half an hour; before which time, a great part of the phlegm will be separated from the spirit; and will appear, together with the undissolved part of the salts, in the bottom of the bottle. Let the spirit then be poured off, or freed from the phlegm and salts by means of a tritorium or separating funnel; and let half an ounce of the pearl ashes, heated and powdered as before, be added to it, and the same treatment repeated. This may be done a third time, if the quantity of phlegm separated by the addition of the pearl-ashes appear considerable. An ounce of alum reduced to powder and made hot, but not burnt, must then be put into the spirit; and suffered to remain some hours; the bottle being frequently shaken: after which, the spirit, being poured off from it, will be fit for use."

The addition of the alum is necessary, to neutralize the remains of the alkaline salt or pearl-ashes; which would otherwise greatly deprave the spirit with respect to varnishes and lacquer, where vegetable colours are concerned; and must consequently render another distillation necessary.

The manner of using the seed-lac, or white varnishes, is the same, except with regard to the substance used in polishing; which, where a pure white, or great clearness of other colours, is in question, should be itself white: whereas the browner sorts of polishing dust, as being cheaper, and doing their business with greater dispatch, may be used in other cases. The pieces of work to be varnished should be placed near a fire, or in a room where there is a stove, and made perfectly dry; and then the varnish may be rubbed over them by the proper brushes made for that purpose, beginning in the middle, and passing the brush to one end; and then with another stroke from the middle, passing it to the other. But no part should be crossed or twice passed over, in forming one coat, where it can possibly be avoided. When one coat is dry, another must be laid over it; and this must be continued at least five or six times, or more; if, on trial, there be not a sufficient thickness of varnish to bear the polish, without laying bare the painting, or the ground colour underneath.

When a sufficient number of coats is thus laid on, the work is fit to be polished: which must be done, in common cases, by rubbing it with a rag dipped in Tripoli or pumice stone, commonly called rotten stone, finely powdered: but towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with the oil alone, to clean it from the powder; and give it a still brighter lustre.

In the case of white grounds, instead of the Tripoli or pumice stone, fine putty or whiting must be used; both which should be washed over to prevent the danger of damaging the work from any sand or other gritty matter, that may happen to be commixed with them.

It is a great improvement of all kinds of japan work, to harden the varnish by means of heat; which, in every degree that it can be applied short of what would burn or calcine the matter, tends to give it a more firm and strong texture. Where metals form the body, therefore, a very hot stove may be used, and the pieces of work may be continued in it a considerable time; especially if the heat be gradually increased: but where wood is in question, heat must be sparingly used, as it would otherwise warp or shrink the body, so as to injure the general figure.

Method of Gilding JAPAN *Work.* See the article GILDING.

JASHER, a book mentioned in Scripture, and said by some to be lost. But some of the most celebrated Hebrew doctors say they have found it; telling us, that it is the book of Genesis, wherein are contained the acts of Abraham, Isaac, Jacob, and the other patriarchs, who were, by way of excellence, called Jasherim the Just: but that man must be easily satisfied, who can acquiesce with this interpretation. Dr. Lightfoot thinks the book of Jasher is the same with the book of the Wars of God; but there is little foundation for it. This book, according to Grotius, was a triumphal poem; but Josephus seems to bid fairest for the truth, who says, that by this book are to be understood certain records kept in some place on purpose, and afterwards in the temple, giving an account of what happened among the Hebrews from year to year, and particularly the prodigy of the sun's standing still, and directions and laws about the use of the bow; that is, the setting up of archery, and maintaining military exercises. If it be enquired why the title given to these Hebrew annals was the book of Jásher; that is, the upright; this may be given as a reason, Because it was by all persons reckoned as a very just and authentic account of all those events and occurrences which it recorded: it was composed with great uprightness and truth; thence it went commonly by the name of Jasher's book, or chronicle. It was not the work of any inspired person, but was of the nature of common civil annals; and, consequently, we cannot infer from hence, that any book properly belonging to the Holy Scripture, that is, that was written by the inspiration of the Holy Ghost, is at this day missing.

JASMINUM, the jaſmine, or jeſſamine-tree, in botany, a genus of plants, the leaves of which are in many ſpecies pinnated; the cup of the flower conſiſts of one leaf, but is divided at the top into five ſegments; the flower conſiſts of one leaf, is funnel-ſhaped, and divided into five ſegments: the flowers are ſucceeded by berries, which ſplit in the middle, each ſide, for the moſt part, containing a ſeparate ſeed.

The common white jaſmine is eaſily propagated by laying down the tender branches in the ſpring, which, by the ſucceeding ſpring, will be rooted ſtrong enough to be tranſplanted. They may alſo be raiſed by cuttings, which ſhould be planted in autumn in a moiſt border, where they may have the morning ſun: but they muſt be ſcreened from the violence of the ſun in the heat of the day, and frequently watered in dry weather. The cuttings, thus managed, will many of them live, and have roots fit to be removed in the following ſpring: but this method is ſeldom practiſed, the layers always making the beſt plants.

The two ſtriped ſorts ſhould be planted in a warm ſituation, eſpecially the white ſtriped; for they are much more tender than the plain, and are very ſubject to be deſtroyed by great froſts, if they are expoſed thereto: it will therefore be proper to preſerve a plant of each kind in pots, which may be removed into the green-houſe in winter, leſt, by expoſing them to the cold, they ſhould all be deſtroyed, and the variety loſt.

JASPER, in natural hiſtory, a genus of ſcrupi, of a complex irregular ſtructure, of great variety of colours, and emulating the appearance of the finer marbles, or ſemipellucid gems.

The great characteriſtic of jaſpers is, that they all readily ſtrike fire with ſteel, and make not the leaſt effervescence with aqua-fortis.

Jaſpers, though commonly reckoned among the precious ſtones, ought undoubtedly to be ranged among the ſcrupi; being only opake cryſtalline maſſes, variouſly debaſed with an earthy admixture: and to this laſt ingredient it is that they owe all their variety of colours, as white, green, red, brown, and bluiſh.

The ſeveral kinds of nephritic ſtone, and the lapis divinus or jade, are all genuine jaſpers; but the hard, bright, green jaſper, of the Eaſt-Indies, ſeems to be the true medicinal kind. It is found in maſſes of various ſizes and ſhapes, but the more uſual ſtandard as to ſize, is between four and ſix inches in diameter; but there are maſſes of it found of a foot or more in diameter, and others no larger than a horſe-bean. It is generally ſimple and unmixed; but if it be variegated at all, it is always with white, and this is diſpoſed not in ſtreaks or veins, but in clouds. It is capable of a very fine poliſh, and when the white clouds are well diſpoſed, is very beautiful, and in pieces not too thick, is tolerably pellucid, when held up againſt the light.

JASPI-CAMEA, in natural hiſtory, the dull, broad-zoned, green and white camea; being a very elegant ſpecies much reſembling the common camea in all things but colour. See CAMEA.

JASPONYX, in natural hiſtory, the pureſt horn-coloured onyx, with beautiful green zones, which are compoſed of the genuine matter of the fineſt jaſpers. See the articles JASPER and ONYX.

JAVELIN, *Haſta*, in antiquity, a ſort of ſpear, five feet and a half long; the ſhaft of which was of wood, with a ſteel point.

Every ſoldier, in the Roman armies, had ſeven of theſe, which were very light and ſlender.

JAUNDICE, in medicine, a diſeaſe ariſing from a vitiated ſtate of the blood and humours, by means of an excrementitious bile, from a fault of the bilious ducts, greatly injuring the functions of the whole body, and rendering the ſkin of a yellow or livid colour.

The bile is a kind of natural ſapo, that is, a mixture of oil, water, and ſalt, both volatile and fixed, ſeparated from the blood in the liver for various uſes of the animal body: and as the blood itſelf may be vitiated many ways, it is no wonder that this humour is ſometimes rendered unfit for its offices. Now it is often faulty by its lentor or viſcidity, and ſometimes alſo for its exceſſive thinneſs. In the firſt caſe the ſecretory glands of the bile are obſtructed, and the ſmall quantity of it that is ſecrated, ſtagnates in the hepatic ducts; whence the liver grows hard, and under its tunicle are formed whitiſh concretions, reſembling hard ſope. But this diſeaſe ariſes, not only from the viſcidity of the bile, whereby it ſtops in its paſſage, but alſo from its want of due conſiſtence: for here the volatile ſalt, which is one of the compounding principles of the bile, over-abounds; whence the bile becomes too thin, hot, and irritating to the inteſtines. In the former caſe the body is too coſtive, and the fæces are hard, and of a clay colour: in the latter a diarrhœa, attended by a fever and thin yellow ſtools, conſtantly teizes the patient. Perſons who ſpend their lives in a ſedentary manner, without proper exerciſe, are moſt liable to the former; becauſe the oily part of the bile grows too thick and viſcid for want of a due proportion of ſalt: and thoſe who render their faculties uſeleſs, by too high feeding and drinking ſpirituous liquors, are generally moſt expoſed to the latter.

But there is another ſpecies of jaundice, owing to a very different cauſe from thoſe above deſcribed; and that is nervous ſpaſms, when the ſubtile elaſtic fluid of the nerves, by becoming too acrid and irritating, conſtringes the bilious ducts to the degree of hindering its paſſage through the liver; and conſequently it muſt remain in the blood, and thence be thrown on the different parts of the body.

I muſt alſo obſerve, that there ſometimes happens another kind of conſtriction, occaſioned by the ſcirrhoſity of the abdominal glands; in which caſe, though the liver and gall bladder be loaded with bile, yet no part of it can paſs into the inteſtines; of which I formerly ſaw a remarkable inſtance in the hoſpital. It was in a working man of about forty-two years of age, who, five months after returning from an acute fever, was ſeized with an inflammation in the right hypochondrium; of which, when he was relieved, he fell into an obſtinate jaundice, with coſtiveneſs and clayey ſtools, and died in a ſhort time. Upon opening the abdomen, we found four pounds of pure blood, in appearance at leaſt, floating in it. We wondered whence this blood proceeded, but ſoon obſerved ſome little membranes, which ſeemed to be the pieces of burſted ſack; and the omentum was mortified in this place. The pancreas was not only ſcirrhous, but alſo cancerous: for upon cutting into it, there flew out into the ſurgeon's face ſome drops of ſerofity of ſo acrid and corroſive a nature, that they burnt the ſkin like oil of vitriol. The ſpleen was ſcirrhous likewiſe. The gall-bladder was very large, and full of bile; not yellow, but of a dark green, and too viſcid. There was no ſcirrhoſity in the liver; but in what part ſoever it was cut, the ſame ſort of bile iſſued. In fine, we obſerved that every part of the body, membranes, fat, glands, nay the very ſubſtance of the ribs, was of a yellow hue, except the muſcular fibres alone, which were not in the leaſt tinged. Upon preſſing the gall-bladder with the fingers, we could not force one drop of bile into the inteſtines; for at the union of the hepatic duct with the cyſtic, the paſſage was ſo vaſtly ſtraightened, that it would not admit a ſtyle. And my reaſon for relating this caſe is, to make appear, from how many different cauſes, and ſome of theſe fatal, this diſeaſe may ariſe.

A diſeaſe attended with ſuch variety of circumſtances, requires different methods of cure. In caſe of coſtiveneſs with aſh-coloured or whitiſh ſtools, ſaponaceous medicines, both alone and joined with rhubarb, are neceſſary. When the belly is too looſe, the looſeneſs is rather to be moderated than ſtopped; which is beſt done by rhubarb with the admixture of an anodyne. But paregorics are never more proper in this diſeaſe than in thoſe caſes, which we have ſaid to be owing to a conſtriction of the biliary ducts by nervous ſpaſms: but in every kind of jaundice, attended with actual inflammation, blood is to be drawn; and, generally ſpeaking, a vomit is to be given. This inflammation frequently ſuppurates and turns to a vomica; from which, if pure white matter iſſues, it is a promiſing ſign, becauſe the evil lies in the tunicle or outward membrane. But if the whole ſubſtance of the liver is conſumed with it, the patient labours under a ſlow fever and great anxiety for a good while, and then dies.

Laſtly, for correcting the bile itſelf nothing is more uſeful than the following draught.

Take of lemon juice ſix drams; of ſalt wormwood half a dram; of ſimple cinnamon-water one ounce; of double refined ſugar one ſcruple: mix.

And it will be of ſervice likewiſe, in caſe of a looſeneſs, if its irritating quality be duly checked by opiates. Upon the ſame principle, Mynſicht's elixir of vitriol, taken in Bath or Spaw water, is a very good medicine. *Mead's Monita & Præcepta.*

JAW, *Maxilla*, in anatomy. See the article MAXILLA.

IBERIS, ſciatica-creſs, in botany, a genus of plants, the corolla whereof conſiſts of four unequal petals, vertically oval, obtuſe, and patent; the fruit is a little pod erect, roundiſh, compreſſed, ſurrounded by an acute bifid margin on the upper ſide, and containing two cells: the ſeed, in each cell, is ſingle and roundiſh.

IBEX, in zoology, an animal of the goat-kind, with extremely long nodoſe horns, which bend backwards, and are of a blackiſh colour, and annulated on the ſurface. The body is of a dark duſky colour, and is leſs in proportion to the height than that of the common goat: it has a great reſemblance to the deer-kind; the legs are alſo perfectly, like thoſe of the deer, ſtraight, elegant, and ſlender. It is frequent in many parts of Europe, and, notwithſtanding its vaſt horns, runs and leaps with ſurpriſing force and agility.

IBIS, a bird which was very uſeful to the Egyptians for deſtroying ſerpents, locuſts, and caterpillars; and, on that account, had divine honours paid it.

It is all over black, and about the ſize of the curlew, with the head of a cormorant, and the long neck of a heron.

ICE, *Glacies*, in phyſiology, a ſolid, tranſparent, and brittle body, formed of ſome fluid, particularly water, by means of cold. See COLD, FROST, and FREEZING.

ICE-HOUSE, a building contrived to preſerve ice for the uſe of a family in the ſummer ſeaſon.

Ice-houſes are more generally uſed in warm countries, than with us, particularly in Italy, where the meaneſt perſon, who rents a houſe, has his vault or cellar for ice.

ICH DIEN, the motto of the prince of Wales's arms, ſignifying, in the High Dutch, I ſerve.

ICHNEUMON, in zoology, the name of an animal, of which there have been a multitude of idle and fabulous things aſſerted. It is a creature of the weaſel kind, with a longer and narrower body than a cat, and ſomething approaching both in ſhape and colour to the badger. Its noſe is black and ſharp, like that of a ferret. It has no beard, or whiſkers: its noſe is prominent, and its ears ſhort and round. Its colour is a yellowiſh grey, much like that of ſome of the monkey claſs. This is its appearance when in a good humour; but, when frighted or provoked, it raiſes its hairs upright, and ſhews them variegated at intervals with grey and yellow in diſtinct portions. Its legs are ſhort, and its feet have all five toes. Its tail is very long, and thick at the inſertion; its teeth, and its tongue, like thoſe of the cat: and, what is very ſingular, is, that in both ſexes it has a large aperture ſituated below the anus, which it dilates and contracts at pleaſure. Hence came the old opinion, that both male and female conceived, and brought forth young, in this animal. It is naturally a very cleanly animal, and is very briſk and nimble, and of great courage. It will engage a large dog; and if it have a quarrel with a cat, will deſtroy that creature by three bites on the throat. Its noſe is ſo ſharp and narrow, that it can very hardly lay hold of any thing large with its teeth, and ſcarce can bite a man's clenched fiſt. It is very expert in ſeizing its prey; it ſtands erect on its hinder-legs, to deſcry where it is; then, throwing itſelf flat on its belly, crawls very ſlowly towards it, and when within reach, darts violently upon it. It feeds indifferently on all animals that it can get at. Its common food are the ſnail, the lizard, the chameleon, ſuch ſerpents as it can manage, and frogs and mice; it is alſo very fond of birds, and of none ſo much as the hen and chicken.

ICHNEUMON is alſo the name of a genus of flies, of the hymenoptera order, with a triple ſting at the anus.

ICHNOGRAPHY, in perſpective, the view of any thing cut off by a plane parallel to the horizon, juſt at the baſe of it.

Among painters it ſignifies a deſcription of images, or of ancient ſtatues of marble and copper, of buſts and ſemi-buſts, of paintings in freſco, Moſaic works, and ancient pieces of miniature.

ICHNOGRAPHY, in architecture, a deſcription or draught of the platform or ground-work of a houſe, or other building. Or it is the geometrical plan or platform of an edifice or houſe, or the ground-work of an houſe or building, delineated upon paper, deſcribing the form of the ſeveral apartments, rooms, windows, chimnies, &c. See the article BUILDING.

ICHNOGRAPHY, in fortification, denotes the plan or repreſentation of the length and breadth of a fortreſs, the diſtinct parts of which are marked out, either on the ground itſelf, or on paper.

ICHOGLANS, the grand ſignior's pages, ſerving in the ſeraglio.

ICHOR properly ſignifies a thin watery humour, like ſerum; but is ſometimes alſo uſed for a thicker kind, flowing from ulcers, called likewiſe ſanies.

ICHTHYOCOLLA, vulgarly called iſinglaſs, a ſolid glutinous ſubſtance, prepared from a fiſh of the ſturgeon kind caught in the rivers of Ruſſia and Hungary. The ſkin, fins, &c. are boiled in water, the decoction inſpiſſated to a due conſiſtence, and then poured out ſo as to form thin cakes; which are either exſiccated in that form, or cut while ſoft into ſlices, and rolled up into ſpiral, horſe-ſhoe, and other ſhapes. The beſt is thin, clear, and almoſt tranſparent pieces.

Ichthyocolla is one of the pureſt and fineſt of the animal glues, of no particular ſmell or taſte. Beaten into ſhreds, it diſſolves pretty readily in boiling water or milk, and forms a gelatinous ſubſtance, which yields a mild nutriment, and proves uſeful medicinally in ſome diſorders ariſing from a ſharpneſs and colliquation of the humours. A ſolution of it in water, curiouſly ſpread, whilſt hot, upon ſilk, affords an elegant ſticking plaſter for ſlight injuries of the ſkin, not eaſily ſeparable from the part by water, and ſcarcely inferior to the more compounded one, ſold under the name of the ladies black plaſter, in which different balſams and reſins are joined to the ichthyocolla.

ICHTHYOLOGY, *ιχθυολογια*, the ſcience of fiſhes, or that branch of zoology which treats of fiſhes. See the article FISH.

ICHTHYOLOGIST, an author who has written profeſſedly of fiſhes.

ICHTHYS, *ιχθυς*, in antiquity, a celebrated acroſtic of the Erythræan ſibyl; the firſt words of each verſe of which were, Ιησους Χριστος Θεου υιος σωτηρ, that is, *Jeſus Chriſtus Dei filius ſervator*; and the initial Greek letters form the word *ιχθυς*, whence the name.

ICONOCLASTS, *εικονοκλαστοι*, in church hiſtory, an appellation given to thoſe perſons, who, in the eighth century, oppoſed image-worſhip; and is ſtill given by the church of Rome, to all Chriſtians who reject the uſe of images in religious matters. See IMAGE.

ICOSAHEDRON, a regular ſolid, terminated by twenty equilateral and equal triangles.

The word is Greek, and compounded of *εικοσι*, twenty, and *εδρα*, a baſe.

It may be conſidered as conſiſting of twenty triangular pyramids, whoſe vertices meet in the center of a ſphere that circumſcribes them, and therefore have their heights and baſes equal; wherefore the ſolidity of one of theſe pyramids multiplied by twenty, the number of baſes, gives the ſolid content of the icoſahedron.

ICOSANDRIA, in the Linnæan ſyſtem of botany, a claſs of plants, the twelfth in order, the characters of which are theſe; the cup of the flower is monophyllous and hollow, with the corolla affixed by the ungues to its ſides, and about twenty ſtamina inſerted either into the ſide of the cup, or corolla. See the article BOTANY.

The term icoſandria is here taken in a lax and indeterminate ſenſe, ſo as to comprehend all plants with more than twelve ſtamina, and for the moſt part not much exceeding twenty; however, the characteriſtic of the claſs

is rather to be taken from the manner of inſertion, than number of the ſtamina.

To this claſs belong the cactus or torch-thiſtle, the amygdalus or almond-tree, the ceraſus, or cherry, &c.

ICTERIC Disease, the ſame with the jaundice. See Jaundice.

IDEA, the repreſentation or reſemblance of ſomething, even though not ſeen, as conceived by the mind.

The word is Greek, ſignifying the ſame thing, and derived from εἰδω, to ſee.

As to the origin of ideas, the Peripatetics maintain that external objects emit ſpecies entirely reſembling them, and that theſe ſpecies ſtriking on our ſenſes are by them tranſmitted to the underſtanding; that being material, they are rendered intelligible by the active intellect, and are at length received by the paſſive.

Others think that our ſouls have of themſelves the power of producing ideas of things we would think upon, and that they are excited to this by the impreſſions which objects make on our ſenſes, though theſe impreſſions are not images of any thing reſembling the objects that occaſioned them.

Others maintain that the mind, by conſidering itſelf and its own perfections, can diſcover all things that are without. Others, with Des Cartes, hold that our ideas are innate or born along with us.

Malebranche and his followers maintain that God has in himſelf the ideas of all the beings he has created, and thus he ſees all things in conſidering his own perfections to which they correſpond; and that, as he is intimately united to our ſouls by his preſence, our minds perceive things in him which repreſent created beings; and that thus we come by all our ideas: and yet, ſays he, though we ſee all ſenſible things in God, we have not our ſenſations in him: for in our perception of any ſenſible object is included both a ſenſation and a pure idea. The ſenſation is a modification of the ſoul, and it is God who cauſes it in us; but the idea joined with the ſenſation is in God, and it is in him we ſee it.

The Carteſians diſtinguiſh three kinds of ideas; the firſt innate; ſuch as we have of God, as a being infinitely perfect: ſecondly, adventitious, which the mind receives in proportion as objects preſent themſelves to our ſenſes: thirdly, factitious, thoſe which the mind forms by aſſembling and combining the ideas it already had, and theſe are called complex. But Mr. Locke has made it appear that all our ideas are owing to our ſenſes, and the reflection of our minds upon thoſe ideas which the ſenſes have at firſt furniſhed us with; and that the diſtinction of the Carteſians is mere chimera. See *Locke's Eſſay on the Human Underſtanding*.

So that a perſon deſtitute of one ſenſe would have no idea belonging to that ſenſe; and if deſtitute of all the ſenſes, he would have no idea at all, not even of reflection, as wanting all ſenſation that ſhould excite in him the operations of his mind, which are the objects of his reflection. Thus far the mind is altogether paſſive.

Ideas only ſeem to be innate, becauſe we find we have them, as ſoon as we come to the uſe of reaſon, being in effect what we formed from the ideas wherewith the mind was inſenſibly filled by the ſenſes.

Ideas are divided into ſimple and complex.

Simple Ideas comprize all thoſe which come into the mind by ſenſation; ſome of which we acquire purely by means of one ſenſe; others by ſeveral ſenſes: there are other ſimple ideas formed in the mind both by ſenſation and reflection jointly. Of ſome of theſe kinds of ideas all our knowledge conſiſts.

We ſhould diſtinguiſh between ſimple ideas, as they are perceptions in the mind, and as they are modifications of the bodies that cauſe ſuch perceptions, that we may not think they are exactly the images of ſomething inherent in the object; for moſt of thoſe of ſenſation are in the mind no more the likeneſs of any thing exiſting without us, than the names that ſtand for them are the likeneſs of the ideas.

But here the qualities of the bodies which produce theſe ideas in us are to be diſtinguiſhed into primary and ſecondary: the former are ſuch as are utterly inſeparable from the body, in whatever ſtate it be, and ſuch as our ſenſes conſtantly find in every particle of matter, as ſolidity, extenſion, &c. Secondary qualities are ſuch as are only powers in the objects to produce various ſenſations in us by means of their primary ones, as the figure, bulk, &c. of their particles, as colour, taſte, &c.

Now the ideas of primary qualities are in ſome ſenſe reſemblances of them; but thoſe produced in us by the ſecondary qualities have no reſemblance of them at all, being only a power to produce thoſe ſenſations in us.

The mind has ſeveral faculties of managing theſe ſimple ideas, as 1. That of diſtinguiſhing rightly between one and another, wherein conſiſts the accuracy of judgment. 2. That of comparing them one with another, as to extent, time, place, or any other circumſtances of relation. 3. That of putting together the ſimple ideas of ſenſation and reflection, in order to form complex ones. 4. Children, having got ſome ideas, by degrees learn the uſe of ſigns: hence the uſe of words being to ſtand as outward marks of our internal ideas, if every particular idea that we take in, ſhould have a particular name affixed to it, names would grow endleſs. To prevent this, the mind has another faculty, whereby it can make the particular ideas received from ſuch objects become general; which is done by conſidering them as they are appearances in the mind ſeparate from all other exiſtences, and circumſtances of exiſtence, &c. and this is called abſtraction. Thus the ſame colour being obſerved to day in chalk, which we obſerved yeſterday in paper, we, conſidering that appearance alone, make it a repreſentation of all the ſame kind, and call it whiteneſs.

From theſe four powers all our complex ideas are formed: and as before the underſtanding was paſſive, ſo here it is active.

Complex Ideas may be reduced to theſe three heads, namely, modes, ſubſtances, and relations: modes are ſuch complex ideas as are not ſuppoſed to exiſt by themſelves, but are conſidered as dependencies on ſubſtances, as triangle, gratitude, &c. Of theſe there are two kinds, 1. Such as are only variations of the ſame ſimple idea, as ten, a ſcore, &c. 2. Such as are compounded of ſimple ideas of ſeveral ſorts put together, to make a complex one, as beauty, theft, &c.

Subſtances have their ideas from ſuch combinations of ſimple ideas as repreſent diſtinct things ſubſiſting by themſelves; in which the idea of ſubſtance, confuſed as it is, is always the firſt. Relations are complex ideas ariſing from the compariſon of one idea with another. Of theſe ſome only depend on the equality or exceſs of the ſame ſimple idea in ſeveral ſubjects, and theſe may be called proportional relations, ſuch as equal, more, &c. Another occaſion of comparing things is owing to the circumſtances of their original, which, not being afterwards to be altered, make the relations depending thereon as laſting as the ſubjects to which they belong; as father, mother, &c. as alſo in the relations by inſtitution, as prince and people, &c. and as to moral relations, they are the conformity or diſconformity of men's free actions to laws and rules, whether human or divine.

Ideas may alſo be divided into clear or diſtinct, and obſcure or confuſed.

Simple ideas are clear, when they continue ſuch as the objects repreſent them; when our organs of ſenſation are in a good tone, our memories retain them, and can preſent them to the mind, whenever it has occaſion to conſider them; and when the mind alſo ſees that thoſe ſimple ideas are ſeverally different one from another. The contrary to which is, what we call obſcurity and confuſion of ideas.

Again ideas, with regard to their objects, are diſtinguiſhed into real or fantaſtical, true or falſe, adequate or inadequate.

Real Ideas are ſuch as have a foundation in nature, being conformable to that being to which they are referred as their archetypes.

Fantaſtical Ideas, ſuch as have no foundation in nature.

True and Falſe Ideas.—When the mind refers its ideas to any thing extraneous to it, in ſuch a reference, the mind makes a tacit ſuppoſition of their conformity to that thing; which ſuppoſition as it is true or falſe, ſo the ideas themſelves come to be denominated. Real ideas are divided

vided into adequate and inadequate; adequate ideas are thoſe which perfectly repreſent thoſe archetypes which the mind ſuppoſes them taken from, and which it makes them ſtand for; inadequate are ſuch as do but partially repreſent thoſe archetypes.

IDENTITATE NOMINIS, in law, a writ that lies where a perſon is impriſoned inſtead of another of the ſame name, commanding the ſheriff to enquire whether the priſoner be the perſon againſt whom the action was brought, or not; and if not, to diſcharge him.

IDENTITY, or SAMENESS, denotes that by which a thing is itſelf, and not any thing elſe; in which ſenſe, identity differs from ſimilitude as well as diverſity.

IDES, *Idus*, in the Roman calendar; eight days in each month are ſo denominated, commencing in the months of March, May, July, and October, on the fifteenth day, and in the other months on the thirteenth, and reckoned backward, ſo as in the four months above ſpecified to terminate on the eighth day, and in the reſt on the ſixth.

The word is variouſly derived; it ſeems moſt probably to be formed of the Etrurian word *iduo*, for *divido*, to divide; becauſe the ides divided the month into two equal parts.

The ides came between the calends and nones. The fourteenth day of March, May, July, and October, and the twelfth of the other eight months, was *pridie idus*, or the eve of the ides: the thirteenth in the four months, and the eleventh in the other eight, was called 3 idus, or the third of the ides of ſuch months: and ſo on to the eighth and ſixth days, which made the eighth of the ides, 8 idus.

This method of reckoning is ſtill retained in the Roman chancery, and calendar of the breviary.

The ides of May were conſecrated to Mercury; thoſe of March were eſteemed unhappy after Cæſar's murder on that day: the time after the ides of June was reckoned fortunate for thoſe who entered into matrimony; the ides of Auguſt were conſecrated to Diana, and obſerved as a feaſt-day by the ſlaves. On the ides of September auguries were taken for appointing the magiſtrates, who formerly entered upon their offices on the ides of May, afterwards on thoſe of March.

IDIOM, *Idioma*, either the peculiarities of a language, or the particular dialect of ſome province, differing in ſome reſpects from the language of the nation in general, from which it is derived.

The word is Greek, ἰδίωμα, ſignifying the ſame thing, and derived from ἴδιος, proper, or one's own.

IDIOPATHY, in phyſic, a diſorder peculiar to a certain part of the body, and not ariſing from any preceding diſeaſe; in which ſenſe it is oppoſed to ſympathetic. Thus, an epilepſy is idopathic, when it happens merely through ſome fault in the brain; and ſympathetic, when it is the conſequence of ſome other diſorder.

IDIOSYNCRASY, among phyſicians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain diſorders, than perſons of a different conſtitution uſually are. See the article TEMPERAMENT.

IDIOT, in the Engliſh laws, denotes a natural or fool from his birth.

The word is derived from the Greek, ἰδιώτης, which primarily imports a private man, who bears no office in the government; but figuratively it implies a ſuperlative fool, even though concerned in government. It is formed of ἴδιος, proper, or private.

A perſon who has underſtanding enough to meaſure a yard of cloth, number twenty rightly, and tell the days of the week, &c. is not an idiot in the eye of the law.

In other countries, repeating the Lord's prayer ſaves a man from being reckoned an idiot.

IDOLATRY, the adoration paid to idols and falſe gods, which is due to God alone.

The word is derived from the Greek, εἰδωλολατρεια, and compounded of εἰδωλον, idol, and λατρεια, worſhip, from λατρης, a ſervant.

Dr. Owen divides the whole of idolatrous worſhip into Sabaiſm and Helleniſm. Dr. Prideaux imagines the planets, as mediators, to be the firſt objects of idolatrous worſhip: though Helleniſm conſiſts principally in the worſhip of dead men and dæmons, yet the Grecians at firſt adored the ſun, moon, and ſtars, as even Plato owns; for, perceiving all things to run in a continual courſe, they called them θεους, gods, from θειν, to run. The Greek and Roman idolatry took its riſe from that of the Egyptians, Phœnicians, and Syrians. It is a certain maxim, that religion, as well as learning, and mankind itſelf, had its firſt original in the Eaſt. We ſhall therefore conſider that country firſt. Though the Egyptians were reputed the wiſeſt of the Gentiles, yet they appear, in their religious worſhip of beaſts, to have acted contrary to common ſenſe. It is alledged, the worſhip of brutes was the vail, under which were concealed the myſteries of their religion, as their morals were hid under hieroglyphics. But it is abominable to adore ſheep, cats, bulls, dogs, cows, ſtorks, apes, birds of prey, wolves, and ſeveral ſorts of oxen, as the Egyptians did, under any pretence whatever; the very heathens ridiculed this kind of idolatry; each province and diſtrict in Egypt entertained a peculiar devotion for ſome beaſt or other. What was ſignified by this monſtrous Egyptian idolatry is not eaſy to conceive; many fables have been invented to palliate its enormities. This idolatry had footing in Egypt, in the time of Moſes and the Patriarchs. Thus much for the Egyptian idolatry. The Phœnicians were among the moſt ancient nations and firſt idolaters; but all the account we have of their theology is in a little fragment preſerved by Euſebius little to be depended on.

It appears that the ſun, moon, and hoſt of heaven were worſhipped by the Jews, when they turned to idolatry, after the example of neighbouring heathens, without images, by an humble proſtration before them, or their emblems, light or fire: we muſt farther remark, though the Jews were guilty of ſeveral kinds of idolatry, eſpecially before the Babyloniſh captivity, yet the heathens very unjuſtly charged them with ſeveral acts of idolatry of which they were innocent.

However, the long abode of the Iſraelites in Egypt left in them a ſtrange propenſity to idolatry, which neither the miracles of Moſes, nor the rigour of his laws againſt the worſhip of idols, nor the ſplendid marks of God's preſence in the Iſraelitiſh camp, were ſufficient to overcome; they had contracted ſuch an invincible proneneſs to idolatry, that they not only perſiſted in the worſhip of the Egyptian deities, but adopted moreover every new one which came in their way, as they became acquainted with other nations. Moſes has recorded many inſtances of their idolatry; but they were guilty of many more, which have been preſerved by other inſpired writers, who ſeverally upbraid them with ſetting up and carrying about the idols of Remphan, Malkom, and many others of the like nature.

Saul and David, with all their authority, were not able to root out idolatry from among this people; they ſacrificed upon high places, they conſulted divines and magicians. Solomon himſelf, whom God had choſen to build his temple, erected altars to the falſe gods of the Phœnicians, Moabites, and Ammonites, &c. and there were few of the kings his ſucceſſors who did not in this reſpect ſhew a like weakneſs; thus Jeroboam, the ſon of Nebat, king of Iſrael, introduced the worſhip of the golden calves, which took ſo deep root in the kingdom of Iſrael, that it never was entirely extirpated.

Leaving the Eaſtern nations, it is now proper to remove to the Weſt, and conſider the idolatry of the Greeks and Romans, and other Weſtern nations, before Chriſt. Nothing can be more monſtrous than the idolatry of the Greeks and Romans, contained in their poets and claſſics in the hands of every child, where we meet with an incredible number of them.

The ancient Britons had abundance of magical rites, and adored a multiplicity of idols. The Germans had the ſame idols as the Britons: for, from the heathen Saxons, the Engliſh learned their idolatry.

Sozomen, with Origen and others affirm, that, when our Saviour was carried into Egypt, to avoid the perſecution of Herod, the idols of this country, which were very numerous, and worſhipped to the greateſt degree of ſtupidity and exceſs, were moſt of them ſhaken off their baſis; however, though idolatry was not perfectly ſuppreſſed,

preſſed, but was ſtill kept on foot in the ſame meaſure even in Rome, this is certain, that it began to be laid aſide after our Saviour's birth; the emperor Theodoſius, jun. deſirous to put a final end to the great work of aboliſhing idolatry, publiſhed very ſevere edicts, wherein he ordered all things belonging to idolatry to be deſtroyed throughout the Roman empire. At preſent idolatry flouriſhes moſt in China.

IDYLLION, εἰδύλιον, in ancient poetry, is only a diminutive of the word εἶδος, and properly ſignifies any poem of moderate extent, without conſidering the ſubject. But as the collection of Theocritus's poems were called Idyllia, and the paſtoral pieces being by far the beſt in that collection, the term idyllion ſeems to be now appropriated to paſtoral pieces. See the article PASTORAL POETRY.

So very different are our modern idyllions from thoſe of the ancients, by introducing none but allegorical ſhepherds, that a literal tranſlation of Theocritus's idyllions, however well executed, would be reliſhed only by people of taſte, and thoſe too well acquainted with the ſimplicity and manners of the ancients.

JEALOUSY, in general, denotes the fear of a rival; but is more eſpecially underſtood of the ſuſpicion which married people entertain of each other's fidelity and affection.

Bitter Waters of JEALOUSY, in Jewiſh antiquity, certain conſecrated waters, which a woman was obliged to drink, in order to clear herſelf of the crime of adultery, whereof her jealous huſband accuſed her; the conſequence of which draught was, that if innocent ſhe ſuffered no harm, but if guilty her belly ſwelled, &c.

JEARS, in the marine, a certain double tackle or complication of pullies, whereby to raiſe the principal ſail-yards of a ſhip, particularly thoſe of the main, fore, and mizen-ſails.

JECUR, the liver, in anatomy. See the article LIVER.

JEHOVAH, one of the Scripture names of God, ſignifying the Being who is ſelf-exiſtent, and gives exiſtence to others. See the article GOD.

JEJUNUM, in anatomy, the ſecond of the ſmall guts, ſo called becauſe it is uſually found empty. This is owing to the fluidity of the chyle, the greater ſtimulus of the bile in it, and the abundance of the lacteal veſſels with which it is furniſhed. Its ſituation is in the region above the navel; it has a great many connivent glands. Its beginning is where the duodenum ends; and it terminates where theſe valves are obliterated. Its length is different in various ſubjects; but is uſually between thirteen and ſixteen ſpans.

JEOFAILE, or JEOFAYLE, in law, a term uſed for an overſight in pleading, or other proceedings in law.

JESUITS, or the ſociety of Jeſus, a moſt famous religious order in the Romiſh church, founded by Ignatius Loyola, a native of Guipuſcoa in Spain, who in the year 1538, aſſembled ten of his companions at Rome, principally choſen out of the univerſity of Paris, and made a propoſal to them to form a new order; when, after many deliberations, it was agreed to add to the three ordinary vows of chaſtity, poverty, and obedience, a fourth, which was, to go into all countries whither the pope ſhould pleaſe to ſend them, in order to make converts to the Romiſh church. Two years after, pope Paul III. gave them a bull, by which he approved this new order, giving them a power to make ſuch ſtatutes as they ſhould judge convenient; on which, Ignatius was created general of the order; which in a ſhort time ſpread over all the countries of the world, to which Ignatius ſent his companions, while he ſtaid at Rome, from whence he governed the whole ſociety.

The entire ſociety is compoſed of four ſorts of members; novices, ſcholars, ſpiritual and temporal coadjutors, and profeſſed members. The novices continue ſo two years, after which they are admitted to make the three ſimple vows, of chaſtity, poverty, and obedience, in the preſence of their ſuperiors: the ſcholars add ſome ſpiritual exerciſes to their ſtudies. The principal coadjutors aſſiſt the profeſſed members, and alſo make the three ſimple vows: the temporal coadjutors, or lay-brothers, take care of the temporal affairs of the ſociety; and the profeſſed members, which compoſe the body of the ſociety, beſides the three ſimple vows, add a ſpecial vow of obedience to the head of the church in every thing relating to miſſions among idolaters and heretics. They have profeſſed houſes for their profeſſed members and their coadjutors; colleges, in which the ſciences are taught to ſtrangers; and ſeminaries, in which the young jeſuits go through a courſe of philoſophy and theology. They are governed by a general, who has four aſſiſtants, and who appoints rectors, ſuperiors of houſes, provincials, viſitors, and commiſſaries. The diſcipline of theſe houſes, and eſpecially of the colleges, was regulated by Ignatius himſelf.

JET, *Gagates*, in natural hiſtory, a ſolid, dry, opake, inflammable ſubſtance, found in large detached maſſes, of a fine and regular ſtructure, having a grain like that of wood, ſplitting more eaſily horizontally than in any other direction, very light, moderately hard, not fuſible, but readily inflammable, and burning a long time with a fine greeniſh flame.

It is of a fine deep black colour, very gloſſy and ſhining, except upon its ſurface, where it has been fouled by accident. When examined by the microſcope, it is found to be compoſed of a number of parallel plates, very thin, and laid cloſely upon one another. It is not ſoluble in, nor makes any effervеſcence with acids. It ſhould be choſen of the deepeſt black, of a moderate hardneſs, very light, and ſuch as will ſplit moſt evenly in an horizontal direction; this being its great characteriſtic, by which it is diſtinguiſhed from the cannel-coal, which breaks equally eaſy any way.

Jet is of great uſe to perfumers, and is ſometimes preſcribed in medicine.

JET D'EAU, a French term, frequently alſo uſed with us, for a fountain that caſts up water to a conſiderable height in the air. See the articles ADJUTAGE and FOUNTAIN.

JETSON, JETSEN, or JETSAM, in law, is uſed for any thing thrown out of a ſhip or veſſel that is in danger of being a wreck, and which is driven by the waves on ſhore. See FLOTSON.

JEWEL, any precious ſtone or ornament beſet with them. See DIAMOND, RUBY, &c.

JEWEL-BLOCKS, among ſailors, certain pullies hung to the outer-ends or yard-arms of the top-ſail yards: they are uſed to hoiſt the ſtudding-ſails by. See the article STUDDING-SAIL.

JEWEL-OFFICE, an office belonging to the crown, that has the charge of faſhioning and weighing the king's plate, and delivering it out by warrants from the lord chamberlain.

The principal officer is the maſter of the jewel-office, who has a ſalary of four hundred and fifty pounds per annum.

JEWS, thoſe who profeſs obedience to the laws and religion of Moſes, before whom every man worſhipped God according to the inclination of his own heart.

How far the religious ceremonies of the Jews were copied from thoſe of the Egyptians, among whom they had ſo long ſojourned, or how far they were typical of ſomething future, are queſtions which we leave to be diſcuſſed by divines. But as to the religion of the modern Jews, it is a manifeſt abſurdity; ſince being without a temple, ſacrifices, &c. it cannot be conſidered as ſubſiſting any longer.

JEWISH HOURS, in chronology. See the article HOUR.

JEZIDES, among the Mahometans, a term of ſimilar import with heretics among Chriſtians.

IGNIS-AQUA, Helmont's name for the alkaheſt. See ALKAHEST.

IGNIS FATUUS, in meteorology, a meteor, otherwiſe called, will-with-a-wiſp. See the article WILL-*With-a-Wiſp*.

IGNIS GEHENNÆ, the ſame with the univerſal diſſolvent, or alkaheſt. See ALKAHEST.

IGNIS JUDICII, in our old cuſtoms, a purgation by fire. See ORDEAL.

IGNITION, in chemiſtry, the heating metals red-hot,

hot, without melting them. Lead and tin are too ſoft to bear ignition, which takes effect only in the harder metals, as gold and ſilver, but eſpecially iron.

IGNORAMUS, in law, a term which ſignifies we are ignorant. This is uſed when the grand jury impannelled on the inquiſition of criminal cauſes, reject the evidence as too weak to make good the preſentment or indictment brought againſt a perſon, ſo as to bring him upon his trial by a petty jury; in which caſe they indorſe this word on the back of the bill of indictment. In conſequence of which, all further proceedings againſt the party accuſed are ſtopped, and the ſuppoſed offender is delivered without further anſwer.

IGNORANCE, *Ignorantia*, the privation or abſence of knowledge. See the article KNOWLEDGE.

IGNORANCE, in law, is a want of knowledge of the laws, which will not excuſe a perſon from ſuffering the penalty inflicted on the breach of them; for every one is obliged, at his peril, to know the laws of the land.

IGUANA, in zoology, an American ſpecies of lizard, with a long round tail, five toes on each foot, and the creſt of the throat and the dorſal future dentated.

JIB, among ſeamen, the foremoſt ſail of a ſhip, or that which is extended the furtheſt before the prow: it is, like all the other ſtay-ſails, of a triangular form, and is hoiſted from the jib-boom towards the fore-top-maſt head.

JIB-BOOM, a certain pole or ſloping maſt, which is run out on a line with the bowſprit, to bear out the jib to its proper extent: this boom can occaſionally be drawn in, which is always the caſe when they come into a harbour, to prevent breaking amongſt the ſhipping at anchor or paſſing.

ILEX, the holm-oak, or evergreen-oak, in botany, a genus of plants, the leaves of which are for the moſt part indented or ſinuated, and in ſome the edges of the leaves are prickly, and are ever-green; it hath amentaceous flowers, which are produced at remote diſtances from the fruit on the ſame tree; the fruit is an acorn, like the common oak.

Theſe trees are propagated by ſowing their ſeeds: the beſt ſeaſon for this work is in the beginning of March; but then, as the acorns are ripe in autumn, they ſhould be preſerved either in ſand, or dry earth, until the ſpring, otherwiſe they will loſe their growing faculty; which is commonly the caſe with thoſe brought annually from Genoa, ſcarce one ſeed in fifty of them ever riſing; however, ſince we have many large trees now in England, which produce good ſeeds, we need not ſend to Italy for them; but were I to adviſe, I ſhould much rather have them from Portugal than Italy; for the voyage being much ſhorter, they are generally brought from thence in very good condition; eſpecially if they are brought over in the paeket-boat to Plymouth.

The manner in which I would adviſe their being ſown is, for large quantities, in drills at about four feet diſtance; but for a ſmall parcel, they muſt be ſown in rows on a bed much nearer.

The ground on which theſe ſeeds are ſown, ſhould be well dug, and cleanſed from the roots of all noxious weeds, &c. and levelled even, and the great clods broken; then draw the rills with an hoe in a ſtraight line, as is practiſed in the ſowing of kidney beans, about two inches deep, laying the acorns therein three or four inches aſunder; then draw the earth over them with a head of a rake, obſerving that none of them are left uncovered, which would intice the vermin to attack your acorns, eſpecially the mice, whereby your ſeminary will be greatly injured, if not wholly deſtroyed.

Theſe trees are by many greatly eſteemed for hedges to ſurround wilderneſs quarters; but they are ſubject to grow too large for that purpoſe, becauſe we ſhould never hide the tops of the trees in ſuch places from the ſight; for they are, if rightly diſpoſed in the quarters, vaſtly more agreeable to the eye than the fineſt ſheared hedge in the world; but they may do well enough for a large fence, to obſtruct the ſight, or to defend a new plantation of tender trees; for which purpoſe the acorns ſhould be ſown in the place where the hedge is deſigned; and when the plants are come up, they ſhould be thinned, where they are too cloſe; and if the ground is kept clear from weeds, and every ſpring dug about the plants, they will ſoon form a good hedge; but you ſhould obſerve, not to let them grow too much in height before the lower part of the hedge is well ſtrengthened, which would occaſion its bending, and the branches would be ſubject to be diſperſed with ſtrong winds, or great ſnows, and thereby become very unſightly; but if they are regularly trained up they will make a good thick hedge from the ground to the height of thirty feet, and that in leſs time than any other ever-green tree whatever.

The ſoil in which theſe trees thrive beſt, is a hazelly loam, not too ſtrong, nor over light, in which they will grow to a large ſize, and reſiſt the ſevereſt cold of our climate; and retaining their leaves all the winter, afford an agreeable proſpect in that ſeaſon: but they ſhould by no means be planted near ſuch walks, or other parts of the garden, as are intended to be kept clean; for in the month of April, when they caſt their old leaves, they make a great litter, and are apt to blow about with the wind, and become very troubleſome; and in June, when their male flowers fall off, they occaſion no leſs trouble to clean them up daily in ſuch places; and in the pleaſanteſt ſeaſon of the year, they are the moſt unſightly trees in a garden, the old leaves decaying at that ſeaſon, and falling off; and the male flowers, which are generally in great plenty, are then produced, which renders it not ſo valuable in places much frequented; but for larger plantations, at a remote diſtance from the habitation, ſo as to be juſt within the view, they make a very handſome appearance, eſpecially in the winter ſeaſon.

The wood of this tree is accounted very good for many ſorts of tools and utenſils, as mallet-heads, mall-balls, chairs, wedges, beetles, pins, &c. as alſo for palliſadoes; and affords the moſt durable charcoal in the world, and is the common fuel in the ſouthern parts of France and Italy. *Miller's Gard. Dict.*

ILEX COCCIGERA, or holm-oak, is of much lower ſtature than the former ſorts, and ſeldom grows to the height of a tree: this, though a native of the warmeſt parts of France, yet will endure the cold of our climate in the open air. It may be propagated in the ſame manner as the former, and deſerves a place amongſt other ſhrubs of low growth, for its curioſity, as being the plant on which the kermes are bred.

ILIAC PASSION, called alſo *Volvulus*, *Miſerere Mi*, and *Chordapſus*, in phyſic, a ſevere kind of colic.

The word is derived from *ileon*, this inteſtine being uſually affected thereby; or perhaps from ειλεω, to twiſt.

This diſeaſe, by the Greeks named ειλεον, and by Celſus the diſeaſe of the ſmaller gut, is very acute. It is a violent inflammation of the inteſtine, which, unleſs ſpeedy relief be given, ſoon terminates in a gangrene, and death.

Wherefore blood muſt be plentifully drawn with great expedition, not once only, but twice, and generally thrice: then the belly is to be moved; but this is very difficult to be done, becauſe acrid cathartics cauſe too great an irritation, and are thrown up by vomit: therefore it is to be attempted by ſtimulating clyſters, and gentle cathartics, which are moſt likely to give mutual aſſiſtance to each other's operation. Anodynes too are neceſſary, but mixed with the purging medicines. Thus a very proper medicine will be a ſcruple of the cathartic extract, with one grain of the Thebaic extract; and ſome hours after, two ſpoonfuls of infuſion of ſena, with the addition of a fourth part of the tincture of ſena, to be taken either every hour, or every two hours, till the patient has had a ſufficient number of ſtools.

If this courſe prove ineffectual, it will be right to order quickſilver to be ſwallowed down; which has a two-fold uſe in this caſe; to wit, by its ponderoſity, that of reſtoring the natural motion of the inteſtines, which is inverted; and by its ſlipperineſs, that of ſoftening and driving downward the excrements which ſtop the paſſage. Upon theſe accounts it is to be given in large quantities, to a pound weight at leaſt; and generally requires to be repeated. Nor ought the phyſician to uſe any long delay in trying this experiment, for fear of an actual mortifica-

tion

tion of the inflamed parts, whereby the coats of the inteſtines are deſtroyed, and the quickſilver runs into the cavity of the abdomen.

In ſhort, fomentations are of ſome ſervice, particularly warm flannels ſoaked in ſpirits of wine; or what Sydenham preſcribes, a live puppy held conſtantly on the bare belly. But an immerſion up to the breaſt in the warm bath is far more beneficial; and if the pain is not diſcuſſed, it will be proper to apply cupping-glaſſes, with ſlight ſcarifications about the navel.

The ſame method of cure is to be obſerved in that ſevere diſeaſe by the French called *colica pictonum*, and by the Engliſh in the American iſlands, where it is very rife, the dry belly ach: for it is a pain attended with a fever and inflammation, and moſt troubleſome coſtiveneſs. *Mead.*

ILIACUS Musculus, in anatomy, a broad thick muſcle, lying on the inſide of the os ilium. It is fixed by fleſhy fibres to the internal labium of the creſt of the os ilium, to that of the ſlope between the two anterior ſpines, to the inſides of theſe ſpines, to the ſuperior half of the inſide of this bone, and to the adjacent lateral part of the os ſacrum. All theſe fibres, contracting by degrees, run obliquely towards the lower part of the muſculus pſoas, uniting with it; and being fixed by a kind of aponeuroſis to the outſide of its tendon, all the way to the little trochanter.

ILIAD, ιλιας, in literary hiſtory, the name of an ancient epic poem, the firſt and fineſt of thoſe compoſed by Homer.

As there was no true hiſtory before the firſt Olympiad, it is reaſonable to ſuppoſe that Homer took the ſubject of his Iliad from thoſe traditional ſtories which were handed down from father to ſon, reſpecting the Trojan war; adding ſuch other characters, allegories, and circumſtances, as were ſuitable to his deſign, which was evidently that of diſplaying to his countrymen, who were Greeks, the miſchievous effects of their too frequent diſſentions, and the benefits ariſing from a contrary conduct.

It is to be obſerved, that at the time Homer wrote this poem, and for ſome centuries before, the Grecians were divided into as many ſmall independent ſtates as they had large cities: and as their body politic and government were diſtinct and different, ſo was too often their intereſt, whence aroſe animoſities and ſometimes wars among themſelves; yet as theſe people had very powerful neighbours, and inveterate enemies, they were often obliged, notwithſtanding their own petty quarrels, to confederate themſelves together under one general for their mutual ſafety: and when they were thus united, and had no contention among them, they were generally victorious, and an over match even for the Perſians; but on the contrary, when by their own feuds and diſſentions, their armies were divided and weakened, their enemies prevailed over them, and part of their country was deſpoiled.

Homer ſaw this, and knowing that an inſtructive leſſon on the ſubject, diſguiſed under the allegories of an important action, and delivered in an inſinuating pleaſing manner, would do more good with ſuch a people than the moſt powerful oratory and argumentation, he compoſed his Iliad for their uſe; the deſign of which is to ſhew, that unanimity and concord among princes and governors occaſioned the preſervation and proſperity of ſtates, and that diſcord brought on their deſtruction. This therefore is the principal moral of the poem; and this he has exemplified in the anger of Achilles and its conſequences, which forms the action and fable of the poem, which is as follows:

Several Grecian princes, independent of each other, are united againſt the Trojans, to revenge themſelves of an inſult offered to Menelaus, king of Sparta. They elect Agamemnon, brother to the injured prince, their general, who by an act of violence affronts Achilles, the moſt valiant of all the confederates; upon which this prince breaks the union, withdraws from the army, and obſtinately refuſes to fight for the common cauſe; whereupon there are contentions among the troops, who grow mutinous, and the Trojans taking advantage of the abſence of Achilles, and of their diſputes and diviſions, recover new ſpirits, deſtroy a great number of the Greeks, and preſs them ſo cloſe, that they are obliged to raiſe fortifications to ſecure their fleet, are about to quit the Phrygian coaſt, and to return home with diſhonour. Agamemnon, by the advice of the other princes, ſolicits a reconciliation with Achilles, but in vain. He continues inexorable, and refuſes them aid, even at a time when all their beſt generals were wounded, their fortifications deſtroyed, and the fleet ſet on fire; at laſt, however, he permits his deareſt friend Patroclus to fight for the Greeks in his armour, who is killed by Hector; this draws the fury of Achilles on the Trojans; and Agamemnon and he having both ſeverely ſuffered for their folly, are made friends: Achilles returning again to the army, kills Hector with his own hand, and the Trojans are vanquiſhed: ſo that in this poem, which does not extend to the deſtruction of Troy, but ends with the death of Hector, becauſe that puts an end to the anger of Achilles, and the action is complete, the poet has fully inculcated his intended moral, by ſhewing the terrible effects which enſued from a diviſion among their princes, and the good effects which attended their union and friendſhip.

To excite curioſity, and raiſe our admiration to the higheſt pitch, he has inſerted many things that are wonderful, and out of nature; but they are generally introduced with the pomp of celeſtial machinery, and by favour of the gods and goddeſſes, in order that they may appear probable, and obtain belief. We are alſo to obſerve, that as valour was a darling paſſion among the Greeks, he has magnified their deeds, that they might read his work with the greater pleaſure, and that the moral might be more effectually fixed upon the mind.

Homer had ſuch a comprehenſive genius, ſuch a fertile fancy, and was ſo well acquainted with perſons and things, and eſpecially with the paſſions and humours of mankind, that the ancients eſteemed him as the great high-prieſt of nature, who was admitted into her inmoſt choir, and inſtructed in her moſt ſolemn myſteries. The characters of his perſons, though very numerous, are drawn with ſo much judgment, with ſuch a ſurpriſing variety, and ſo diſtinguiſhed by their manners and ſentiments; that every one has ſomething peculiar to himſelf, by which he is diſcovered even in his ſpeeches from all the reſt.

The diſtinctions he has obſerved in the different degrees of virtues and vices are extremely exact; and the ſingle quality of courage, which he has given to moſt of his heroes, is ſo wonderfully diverſified, that it appears different in each. Thus in a fine piece of painting, where ſome particular paſſion is repreſented, every face appears affected; but the attitude and turn of the features ſhew, that each is affected in a different manner, or in a different degree.

If we may credit Strabo the hiſtorian and geographer, Homer has been as exact in his deſcription of countries and cities, as in that of his perſons: but what more particularly recommends him to readers of taſte and genius, is his amazing imagination, his fertility of invention, which is indeed the very fountain of all poetry, and diſcovers itſelf in a miraculous manner, not only in his fable, allegories, machinery, and characters, but even in his deſcriptions, images, and ſimilies, which are even bold and animated. Every thing is alive in Homer. There is little of narration; for the perſons appear, as it were, before you, and ſpeak for themſelves. He has, as Ariſtotle obſerves, found out living words, and, by daring tropes and figures, conveys his ſentiments in an unuſual and ſurpriſing manner.

In him a weapon thirſts to drink the blood of an enemy; an arrow is impatient to be on the wing; his heroes are cloathed with courage and fortitude. Even his epithets diſcover his ſtrength of invention, and in many caſes anſwer the end of elaborate deſcriptions, eſpecially when compounded in his manner, as the Cloud-compelling Thunderer, the Far-darting Phœbus, &c. Nor is the force of his invention much leſs obvious in the ſtructure of his verſe, and the dignity and harmony of his numbers, which flow from Homer with ſo much eaſe, ſays Mr. Pope, that one would "imagine he had no other care than to tranſcribe as faſt as the muſes dictated; and at the ſame time with ſo much force and inſpiring vigour, that they awaken and raiſe us like the ſound of a trumpet.

They

They roll along as a plentiful river, always in motion, and always full; while we are borne away by a tide of verſe, the moſt rapid, and yet the moſt ſmooth imaginable.

"Thus on whatever ſide we contemplate Homer, what principally ſtrikes us is his invention. It is that which forms the character of each part of his work; and accordingly we find it to have made his fable more extenſive and copious than any other, his manners more lively and ſtrongly marked, his ſpeeches more affecting and tranſported, his ſentiments more warm and ſublime, his images and deſcriptions more full and animated, his expreſſion more raiſed and daring, and his numbers more rapid and various.

"What he writes is of the moſt animated nature imaginable; every thing moves, every thing lives, and is put in action. If a council be called, or a battle fought, you are not coldly informed of what was ſaid or done as from a third perſon; the reader is hurried out of himſelf by the force of the poet's imagination, and turns in one place to a hearer, in another to a ſpectator. The courſe of his verſes reſembles that of the army he deſcribes. They pour along like a fire that ſweeps the whole earth before it. It is, however, remarkable, that his fancy, which is every where vigorous, is not diſcovered immediately at the beginning of his poem in its fulleſt ſplendor. It grows in the progreſs, both upon himſelf and others, and becomes on fire like a chariot wheel, by its own rapidity. Exact diſpoſition, juſt thought, correct elocution, poliſhed numbers, may have been found in a thouſand; but this poetical fire, this *vivida vis animi*, in a very few. Even in works, where all thoſe are imperfect or neglected, this can overpower criticiſm, and makes us admire even while we diſapprove. Nay, where this appears, though attended with abſurdities, it brightens all the rubbiſh about it, till we ſee nothing but its own ſplendor. This fire is diſcerned in Virgil, but diſcerned as in a glaſs, reflected from Homer, more ſhining than fierce, but every where equal and conſtant. In Lucan and Statius, it burſts out in ſudden, ſhort, and interrupted flaſhes. In Milton, it glows like a furnace kept up to an uncommon ardour by the force of art. In Shakeſpear, it ſtrikes before we are aware, like an accidental fire from heaven: but in Homer, and in him only, it burns every where clearly, and every where irreſiſtibly.

"This ſtrong and ruling faculty was like a powerful ſtar, which, in the violence of its courſe, drew all things within its vortex. It ſeemed not enough to have taken in the whole circle of arts, and the whole compaſs of nature; all the inward paſſions and affections of mankind, to ſupply his characters; and all the outward forms and images of things for his deſcriptions; but, wanting yet an ampler ſphere to expatiate in, he opened a new and boundleſs walk for his imagination, and created a world for himſelf in the invention of fable; for that which Ariſtotle calls the ſoul of poetry, was firſt breathed into it by Homer."

ILIUM, in anatomy, the third and laſt of the ſmall guts, is ſituated principally below the navel, near the oſſa ilii; whence its name. Its length is various: ſometimes not more than fifteen, ſometimes twenty ſpans or more. Its beginning is where the valves of the jejunum ceaſe to be conſpicuous, and its end is where the larger inteſtines begin; in which place it is, in a very ſingular manner, inſerted into the left ſide of the colon. It has no other valves except that great one at the end, which is called, by many, valvula coli Bauhini: its glands are, in general, more numerous towards the end than in any other part.

ILIUM OS. See INNOMINATA OSSA.

IMAGE, in a religious ſenſe, is an artificial repreſentation or ſimilitude of ſome perſon or thing, uſed either by way of decoration and ornament, or as an object of religious worſhip and veneration; in which laſt ſenſe, it is uſed indifferently with the word idol. See the article IDOLATRY.

IMAGINATION, a power or faculty of the mind, whereby it conceives and forms ideas of things communicated to it by the outward organs of ſenſe.

IMAM, a name applied by the Mahometans to him who is head of the congregations in their moſques; and by way of eminence to him who has the ſupreme authority both in reſpect to ſpirituals and temporals.

There are ſubordinate imams in each town who repreſent the chief imam, but only with reſpect to religion. When the imam of the Muſſulman religion is mentioned without diſtinction, it is always reſtricted to the rightful and lawful ſucceſſor of Mahomet, the fountain both of ſecular and ſacred juriſdiction. The Mahometans are not perfectly agreed concerning the dignity of ſome of the circumſtances of this office: ſome hold the imamate to be ſettled by divine right, like the Aaronical prieſthood, in one family: others think it not ſo unalterably tied to genealogy and deſcent, as to hinder its paſſing from one family to another; and they ſay that an imam may be depoſed for vicious conduct, and his office conferred on another.

The Schiites, or diſciples of Ali, maintain, that this privilege belongs to the family of Ali excluſive of all others; Ali being ſole heir to Mahomet: hence, they own no perſon for the head of religion, who cannot prove his deſcent in a right line from this firſt imam. There are imams belonging to particular moſques, who are in the nature of our pariſh-prieſts.

IMBECILITY, a languid, infirm ſtate of body; which, being greatly impaired, is not able to perform its uſual exerciſes and functions.

IMBIBING, the action of a dry porous body, that abſorbs or takes up a moiſt or fluid one: thus, ſugar imbibes water; a ſponge, the moiſture of the air, &c. See MOISTURE, HYGROMETER, &c.

IMBRICATED, among botaniſts, an appellation given to ſuch leaves of plants, as are placed over one another like the tiles of a houſe.

The term imbricated is likewiſe applied to ſome of the heart ſhells, from their being ridged tranſverſely in the ſame manner.

IMITATION, in literary matters, the act of doing or ſtriving to copy after, or become like to another perſon or thing.

IMITATION, in muſic, a particular way of compoſition wherein each part is made to imitate the other, either throughout the whole piece, which is one of the kinds of canon; or only during ſome meaſures, which is a ſimple imitation.

Sometimes the motion or figure of the notes is only imitated, and that often by a contrary motion, which makes what they call a retrograde imitation.

IMMACULATE, ſomething without ſtain, chiefly applied to the conception of the holy virgin. See CONCEPTION.

IMMANENT, in logic. The ſchoolmen diſtinguiſh two kinds of actions, the one tranſient, which paſs from the agent to the patient; the other immanent, which continue in the agent. See ACT.

IMMATERIAL, ſomething devoid of matter, or that is pure ſpirit: thus God, angels, and the human ſoul, are immaterial beings. See the articles GOD, ANGEL, and SOUL.

IMMEDIATE, whatever is capable of producing an effect without the intervention of external means; thus we ſay, an immediate cauſe, in oppoſition to a mediate or remote one. See CAUSE.

IMMEMORIAL, in law, an epithet given to the time or duration of any thing, whoſe beginning we know nothing of.

IMMENSITY, an unlimited extenſion, or which no finite and determinate ſpace, repeated ever ſo often, can equal. See INFINITY.

IMMERSION, that act by which any thing is plunged into water, or other fluid. See FLUID.

Immerſion, in aſtronomy, is when a ſtar or planet is ſo near the ſun with regard to our obſervations, that we cannot ſee it; being, as it were, enveloped and hid in the rays of that luminary. It alſo denotes the beginning of an eclipſe of the moon, or that moment when the moon begins to be darkened, and to enter into the ſhadow of the earth; and the ſame term is alſo uſed with regard to an eclipſe of the ſun, when the diſk of the moon begins to cover it. In this ſenſe emerſion ſtands oppoſed to immerſion, and ſignifies the moment wherein the moon begins to come out of the ſhadow of the earth, or the ſun

ſun begins to ſhew the parts of his diſk which were hid before. See the article ECLIPSE.

Immerſion is frequently applied to the ſatellites of Jupiter, and eſpecially to the firſt ſatellite; the obſervation whereof is of ſo much uſe for diſcovering the longitude. The immerſion of that ſatellite is the moment in which it appears to enter within the diſk of Jupiter, and its emerſion the moment when it appears to come out.

The immerſions are obſerved from the time of the conjunction of Jupiter with the ſun, to the time of his oppoſition; and the emerſions from the time of his oppoſition to his conjunction.

The peculiar advantage of theſe obſervations is, that during eleven months of the year, they may be made at leaſt every other day. The perfection of this theory, and the praxis thereon, we owe to Mr. Caſſini.

IMMORTAL, that which will laſt to all eternity; as having in it no principle of alteration or corruption: thus God and the human ſoul are immortal. See the articles GOD and SOUL.

IMMUNITY, a privilege or exemption from ſome office, duty, or impoſition, as an exemption from tolls, &c.

IMMUTABILITY, one of the divine attributes, founded on the abſolute perfection of the Deity. See GOD.

IMPALED, in heraldry; when the coat of a man and his wife who is not an heireſs are borne in the ſame eſcutcheon, they muſt be marſhalled in pale; the huſband's on the right ſide, and the wife's on the left: and this the heralds call baron and feme, two coats impaled.

If a man has had two wives, he may impale his coat in the middle between theirs; and if he has had more than two, they are to be marſhalled on each ſide of his in their proper order.

IMPALPABLE, that whoſe parts are ſo extremely minute that they cannot be diſtinguiſhed by the ſenſes, particularly by that of feeling.

IMPANELLING, in law, ſignifies the writing down or entering into a parchment, liſt or ſchedule, the names of a jury ſummoned by the ſheriff to appear for ſuch public ſervices as juries are employed in. See the article PANNEL.

IMPARLANCE, in law, a petition in court for a day to conſider or adviſe what anſwer the defendant ſhall make to the plaintiff's action; and is the continuance of the cauſe till another day, or a longer time given by the court.

IMPASSIBLE, that which is exempt from ſuffering, or cannot undergo pain or alteration.

IMPASTATION, in maſonry, a term uſed for a work made of ſtuc, or ſtone, beaten and wrought up in manner of a paſte.

IMPASTING, or EMPASTING, in painting. See EMPASTING.

IMPEACHMENT, an accuſation and proſecution for treaſon and other crimes and miſdemeanors.

IMPEACHMENT *of Waſte*, is a prohibition or reſtraint from committing of waſte upon lands or tenements.

IMPEDIMENTS, in law, are ſuch hindrances as put a ſtop, or ſtay, to a perſon's ſeeking for his right by due courſe of law.

IMPENETRABILITY, in philoſophy, that property of body, whereby it cannot be pierced by another: thus, a body, which ſo fills a ſpace as to exclude all others, is ſaid to be impenetrable. See the articles BODY, EXTENSION, &c.

IMPERATIVE, one of the moods of a verb, uſed when we would command, entreat or adviſe: thus, *go*, *read*, *take pity*, *be adviſed*, are imperatives in our language; but in the learned languages, this mood has a peculiar termination to diſtinguiſh it from others, as *i*, or *ito*, *go*; *lege*, or *legito*, *read*, &c. and not only ſo, but the termination varies, according as you addreſs one or more perſons, as *audi* and *audite*; ακκε[ω, ακκε[ων, ακκε-τωσαν, &c.

IMPERATOR, in Roman antiquity, a title of honour conferred on victorious generals by their armies, and afterwards confirmed by the ſenate.

IMPERATORIA, maſter-wort, in botany, an umbelliferous plant, with large winged leaves, divided into three indented ſegments; producing thick oblong ſtriated ſeeds, ſurrounded with a narrow leafy margin: the roots are oblong, thick, knobby, jointed, with ſeveral lateral fibres, brown on the outſide, and whitiſh within. It is perennial, a native of the Alps and Pyrenees; from whence we are ſupplied with roots ſuppoſed to be ſuperior to thoſe which are raiſed in our gardens.

IMPERFECT, ſomething that is defective, or that wants ſome of the properties found in other beings of the ſame kind: thus moſſes are called imperfect plants, becauſe almoſt all the plants of fructification are wanting in them; and for the like reaſon, is the appellation imperfect given to the fungi and ſubmarine plants.

IMPERFECT FLOWERS, thoſe otherwiſe called ſtamineous. See the article STAMINEOUS.

IMPERFECT NUMBERS, ſuch whoſe aliquot parts taken together, do either exceed or fall ſhort of that whole number of which they are parts: they are either abundant or deficient. See the articles ABUNDANT and DEFICIENT.

IMPERFECT TENSE, in grammar, a tenſe that regards ſome præterite tenſe, or denotes the thing to be at that time preſent, and not quite finiſhed; as *ſcribebam*, *I was writing*.

IMPERIAL, ſomething belonging to an emperor or empire, as imperial crown, imperial chamber, imperial cities, imperial diet, &c.

IMPERSONAL VERB, in grammar, a verb to which the nominative of any certain perſon cannot be prefixed; or, as others define it, a verb deſtitute of the two firſt and primary perſons, as *decet*, *oportet*, &c. The imperſonal verbs of the active voice end in *t*, and thoſe of the paſſive in *tur*; they are conjugated through the third perſon ſingular of almoſt all the tenſes and moods: they want the imperative, inſtead of which we uſe the preſent of the ſubjunctive; as *pæniteat*, *pugnetur*; nor, but a few excepted, are they to be met with in the ſupines, participles, or gerunds.

IMPERVIOUS, a thing not to be pervaded, nor paſſed through, either by reaſon of the cloſeneſs of its pores, or the particular configuration of its parts.

IMPETIGO, in medicine, a name by which the leproſy of the Greeks is ſometimes called. See the article LEPROSY.

IMPETIGO is alſo a ſpecies of itch attended with dry ſcales or ſcurf, and an uneaſy pruriginous itching. See ITCH.

IMPETUS, in mechanics, the force with which one body impels or ſtrikes another. See MOMENTUM, GUNNERY, &c.

IMPING, in falconry, the inverting of a feather in the wing of an hawk, in the place of one that is broken.

IMPLEAD ſignifies to ſue or proſecute by due courſe of law.

IMPLEMENTS is uſed for all things neceſſary for a trade, or the furniture of an houſhold; in which ſenſe it is frequently uſed in wills, conveyances of moveables, &c.

IMPLICATION, in law, is where ſomething is implied that is not expreſſed by the parties themſelves in their deeds, contracts, and agreements.

IMPORTATION, in commerce, the bringing merchandize into a kingdom from foreign countries; in contradiſtinction to exportation. See the article EXPORTATION.

IMPOSITION *of Hands*, a religious ceremony, in which the biſhop lays his hand upon the head of a perſon, in ordination, confirmation, or in uttering a bleſſing. This practice is alſo generally obſerved by the diſſenters at the ordination of their miniſters, when all the miniſters preſent place their hands upon the head of him whom they are ordaining, while one of the body prays for a bleſſing on him and his future labours.

IMPOSSIBLE, that which cannot be done or effected.

A propoſition is ſaid to be impoſſible, when it contains two ideas, which mutually deſtroy each other, and which can neither be conceived nor united together in the mind: thus, it is impoſſible that a circle ſhould be a ſquare,

becauſe we conceive clearly that ſquareneſs and roundneſs deſtroy each other by the contrariety of their figure.

IMPOST, in law, ſignifies in general a tribute or cuſtom; but is more particularly applied to ſignify that tax which the crown receives for merchandizes imported into any port or haven. See DUTY.

Some notwithſtanding, diſtinguiſh impoſts from cuſtoms, which laſt are rather the profits ariſing to the king from goods exported. See the article CUSTOMS.

IMPOSTS, in architecture, the capitals of pillars, or pilaſters, which ſupport arches.

An impoſt, ſometimes called chaptrel, is a ſort of plinth, or little corniche, which crowns a pier, and ſupports the firſt ſtone whence an arch or vault commences. The impoſts are conformable to their proper orders. The Tuſcan has only a plinth; the Doric has two faces crowned; the Ionic, a larmier, or crown over the two faces, and its mouldings may be carved; the Corinthian and Compoſite have a larmier, frieze, and other mouldings.

The projectures of the impoſts muſt not exceed the naked of the pilaſter: ſometimes the entablature of the order ſerves for the impoſt of the arch, and this has a very grand and ſtately appearance. The impoſt is a thing very eſſential to the compoſition of the ordonnances, inſomuch that without it, in the place where the curve-line of the arch meets with the perpendicular line of the pillar, there always ſeems a kind of elbow.

IMPOSTHUME, in ſurgery, &c. the ſame with abſceſs. See ABSCESS.

IMPOTENCE, or IMPOTENCY, in general, denotes want of ſtrength, power, or means to perform any thing.

IMPRACTICABLE CASE, in algebra, that otherwiſe called irreducible. See IRREDUCIBLE.

IMPRECATION, a curſe, or wiſh that evil may befal any one. See EXECRATION.

IMPRESSION is applied to the ſpecies of objects, which are ſuppoſed to make ſome mark or impreſſion on the ſenſes, the mind, and the memory.

IMPRESSION alſo denotes the edition of a book, regarding the mechanical part only; whereas edition, beſides this, takes in the care of the editor, who corrected or augmented the copy, adding notes, &c. to render the work more uſeful. See EDITOR.

IMPRISONMENT, the ſtate of a perſon reſtrained of his liberty, and detained under the cuſtody of another.

IMPROPRIATION, a parſonage or eccleſiaſtical living, the profits of which are in the hands of a layman; in which ſenſe, it ſtands diſtinguiſhed from appropriation, which is where the profits of a benefice are in the hands of a biſhop, college, &c. though theſe terms are now often uſed promiſcuouſly. See the article APPROPRIATION.

IMPUTATION, in general, the charging ſomething to the account of one, which belonged to another: thus, the aſſertors of original ſin maintain, that Adam's ſin is imputed to all his poſterity. See the article ORIGINAL SIN.

In the ſame ſenſe, the righteouſneſs and merits of Chriſt are imputed to true believers. See the article JUSTIFICATION.

INACCESSIBLE, ſomething that cannot be come at, or approached, by reaſon of intervening obſtacles, as a river, rock, &c. It is chiefly uſed in ſpeaking of heights and diſtances. See HEIGHT and DISTANCE.

INACTIVITY *of Matter*. See INERTIA.

INADEQUATE IDEA. See IDEA.

INALIENABLE, that which cannot be legally alienated or made over to another: thus the dominions of the king, the revenues of the church, the eſtates of a minor, &c. are inalienable, otherwiſe than with a reſerve of the right of redemption.

INAMELLING, or ENAMELLING. See the article ENAMELLING.

INANIMATE, a body that has either loſt its ſoul, or that is not of a nature capable of having any.

INANITION, among phyſicians, denotes the ſtate of the ſtomach when empty, in oppoſition to repletion.

INARCHING, in gardening, is a method of grafting, commonly called grafting by approach. See GRAFTING *by Approach*.

INAUGURATION, the coronation of an emperor or king, or the conſecration of a prelate: ſo called from the ceremonies uſed by the Romans, when they were received into the college of augurs. See CORONATION, CONSECRATION, &c.

INCA, or YNCA, a name given by the natives of Peru to their kings, and the princes of the blood. Pedro de Ciéça, in his Chronicle of Peru, gives the origin of the incas, and ſays, that that country was, for a long time, the theatre of all manner of crimes, of war, diſſention, and the moſt dreadful diſorders, till at laſt two brothers appeared, one of whom was called Manco Capac; of this perſon, the Peruvians relate many wonderful ſtories. He built the city of Cuſco, made laws, eſtabliſhed order and harmony by his wiſe regulations, and he and his deſcendants took the name of inca, which ſignifies king or great lord. Theſe incas became ſo powerful, that they rendered themſelves maſters of all the country from Paſto to Chili, and from the river Maule on the ſouth, to the river Augaſmago on the north; theſe two rivers forming the bounds of their empire, which extended above thirteen hundred leagues in length. This they enjoyed till the diviſions between inca Guaſcar and Atabalipa, which the Spaniards laying hold of, made themſelves maſters of the country, and deſtroyed the empire of the incas.

INCAMERATION, a term uſed in the chancery of Rome, for the uniting of lands, revenues, or other rights, to the pope's domain.

INCANTATION, denotes certain ceremonies, accompanied with a formula of words, and ſuppoſed to be capable of raiſing devils, ſpirits, &c.

INCAPACITY, in the canon-law, is of two kinds: 1. The want of a diſpenſation for age in a minor, for legitimation in a baſtard, and the like: this renders the proviſion of a benefice void in its original. 2. Crimes and heinous offences, which annul proviſions at firſt valid.

INCARNATION, in theology, the act whereby the ſecond perſon of the Holy Trinity aſſumed the human nature, viz. a true body and reaſonable ſoul, in order to accompliſh the redemption of fallen man-kind. See TRINITY and REDEMPTION.

This fundamental doctrine of Chriſtianity is very expreſly taught in Scripture: thus, in Gal. iv. 4. it is ſaid, "God ſent forth his ſon, made of a woman:" and 1 John iv. 14. "And we have ſeen and do teſtify, that "the Father ſent the Son to be the Saviour of the "world."

The generation of Chriſt was miraculous, as being conceived by the power of the Holy Ghoſt, and born of the Virgin Mary; from the time of which bleſſed nativity, the chriſtian æra commences. See the article EPOCHA.

INCARNATIVES, in ſurgery, medicines which aſſiſt nature in filling up wounds or ulcers with fleſh; or rather remove the obſtructions thereto. See the article VULNERARY.

Internal incarnatives are aliments which ſupply a balſamic chyle, and conſequently generate fleſh, and produce a full or plump habit.

INCARTATION, among chemiſts, the ſame with depart. See DEPART.

INCENSE, or FRANK-INCENSE, in the materia medica. See the article THUS.

INCEPTIVE, a term uſed by Dr. Wallis to expreſs ſuch moments, or firſt principles, which, though of no magnitude themſelves, are notwithſtanding capable of producing it. Thus, a point is inceptive of a line, and a line inceptive of ſurface, &c.

INCEST, the crime of venereal commerce between perſons who are related in a degree wherein marriage is prohibited by the law of the country.

INCEST SPIRITUAL, a crime committed in like manner between perſons who have a ſpiritual alliance by means of baptiſm or confirmation.

INCH, a well known meaſure of length; being the twelfth part of a foot, and equal to three barley corns in length. See FOOT and MEASURE.

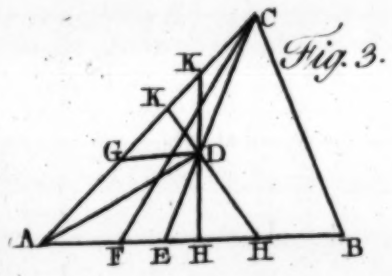

Fig. 3.

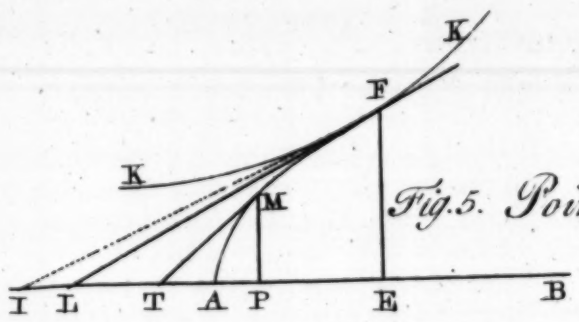

Fig. 5. Point of Inflection.

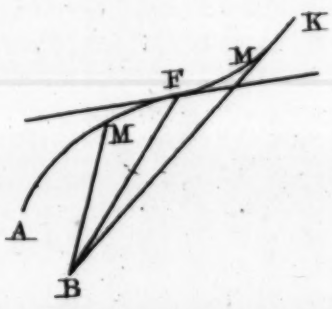

Fig. 6.

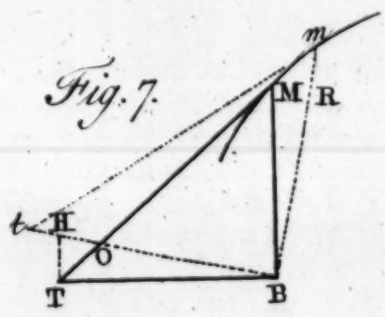

Fig. 7.

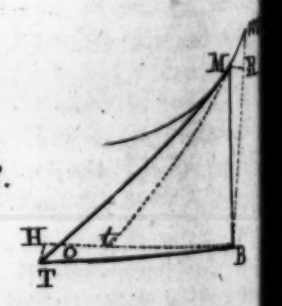

Fig. 8.

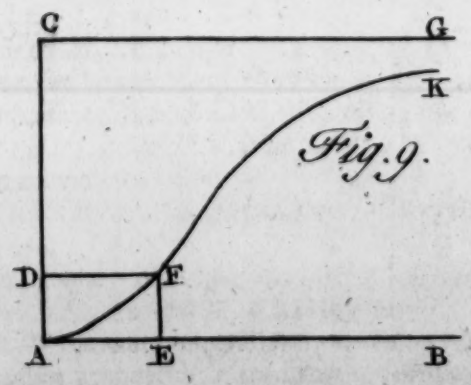

Fig. 9.

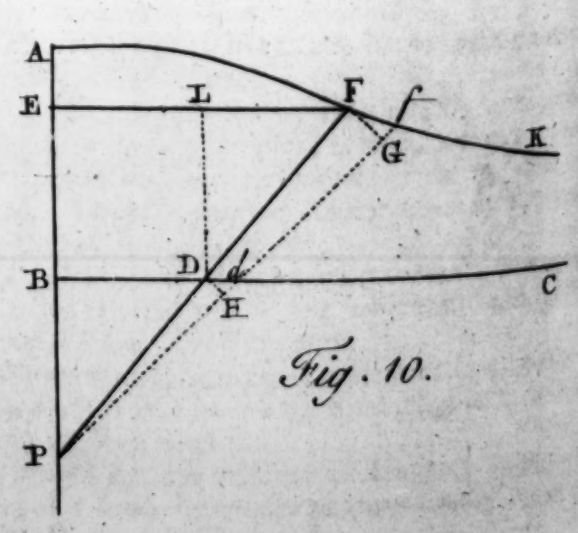

Fig. 10.

INCH *of Candle*, or ſale by inch of candle. See the article CANDLE.

INCIDENCE, in mechanics and optics, denotes the direction in which one body ſtrikes on another. See ANGLE.

INCIDENT, in law, ſomething that inſeparably belongs to another: thus, a court baron is incident to a manor.

INCIDENT, in poetry, denotes much the ſame with epiſode. See EPISODE.

INCISIVE, an appellation given to whatever cuts or divides: thus, the fore-teeth are called *dentes inciſivi*, or cutters; and medicines of an attenuating nature, incidents, or inciſive medicines. See the articles TEETH, and ATTENUANTS.

INCLE, a kind of tape made of linen-yarn.

INCLINATION is a word frequently uſed by mathematicians, and ſignifies the mutual approach, tendency or leaning of two lines, or two planes, towards each other, ſo as to make an angle.

Inclination of a right line to a plane, is the acute angle which that line makes with another right line drawn in the plane through the point where the inclined line interſects it, and through the point where it is alſo cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arch of the circle of inclination, comprehended between the ecliptic and the plane of a planet in its orbit.

The greateſt inclination of Saturn, according to Kepler, is 2° 32′; of Jupiter, 1° 20′; of Mars, 1° 50′ 30″; of Venus, 3° 22′; of Mercury, 6° 54′. According to de la Hire, the greateſt inclination of Saturn is 2° 33′ 30″; of Jupiter, 1° 19′ 20″; of Mars, 1° 51′ 00″; of Venus, 3° 25′ 5″; of Mercury, 6° 52′ 00″.

INCLINATION *of a Plane*, in dialling, is the arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them.

INCLINED PLANE, in mechanics, that which makes an oblique angle with the horizon.

That an inclined plane is a mechanical power appears ſufficiently in its diminiſhing the weight of a body laid upon it in regard to the power which holds it in æquilibrio. Let A (plate LXXVI. *fig.* 1.) be a body ſuſtained on the inclined plane B D; from the center C draw C F perpendicular to the horizon or baſe D C, and C E perpendicular to the plane; then C F will repreſent the whole weight or force of gravity of the body A, which is reſolvable into the two forces C E and E F; but the force C E, being perpendicular to the plane, acts wholly upon it, and is equally re-acted on or ſuſtained by the plane; the other force E F, being parallel to the plane, is that by which the body deſcends, or is kept from deſcending by an equal power acting in a contrary direction. Therefore the whole weight of the body is to the power which keeps it in æquilibrio on the plane as C F to F E, or (becauſe the triangles C F E and B D C are ſimilar) as B D to B C, that is, as the length of the plane to its height.

If it ſhould be required to lift up a very heavy body as W or *w* (*fig.* 2.) the height C B, it would be impracticable to raiſe it up in the line C B without a power whoſe intenſity is equal to that of the weight; and even in that caſe very inconvenient to do it, eſpecially in building. But if an inclined plane A B be laid ariſing from the horizontal line A C, from whence the weight is to be raiſed, a leſs power than the weight will ſerve for that purpoſe, unleſs it puſhes the body directly againſt the plane (as in the direction W T) or draws the body away from the plane (as from W towards *e*, *t*, or L) or in any direction on that ſide of the line E *e*.

The direction in which the body can moſt eaſily be drawn or puſhed up the plane is the line W *w* M, parallel to the plane, and paſſing through the center of the weight; for whether the power divides a plane *k* K (in a direction perpendicular to it) along the line W M, or the power (by its deſcent to *p*) draws it in the ſame line, the velocity of the power will be equal to the line W *w*, the ſpace deſcribed by the center of gravity of the weight, whilſt the ſame weight riſes only the perpendicular height Z B (= *n* W) or has the ſaid line properly to expreſs its velocity. If the body was a cylinder, as a rolling ſtone, and the plane T *t* were to paſs through the gudgeons or axis of the ſaid ſtone; it is evident that the caſe would be the ſame; and as the weight P has its rope running over the roller (or upper pulley) M, the line P *p* will be the velocity of the power. Therefore in this caſe the weight (if kept in æquilibrio) will be to the power, as W *w* (= T B) to *w* Y (= B Z) or as the hypothenuſe A B is to the perpendicular B C, which (by Eucl. 4. 6) are in the ſame proportion; and conſequently, if the power be never ſo little increaſed, it will draw the weight up the plane.

That the power acts with the greateſt advantage, whilſt it draws in the line of direction W *w* (parallel to the plane) is evident, becauſe if one end of the ſaid plane of direction remaining fixed at W, the other ſhould move towards B, or beyond it, then the body would be partly drawn againſt the plane, and therefore the power muſt be increaſed in proportion to the greateſt difficulty of traction: and if the end *w* of the line abovementioned ſhould be carried to D, or beyond it, the power muſt be alſo increaſed, inaſmuch as it endeavours to lift the body off from the plane.

If the power draws in a line of direction W B (*fig.* 2.) parallel to the baſe of the plane; then, in order to keep the weight W in æquilibrio by the power Π, the ſaid power muſt be to the weight, as Z B to Z T, or as the perpendicular B C to the baſe A C of the triangle A C B. For if we ſuppoſe the pulley R at ſo great a diſtance from W, that the line of direction W R may not ſenſibly alter its horizontal poſition, whilſt the body W riſes the height B Z, in ſuch manner that Π *ϖ* (= W Y, and not W *w*) will be the velocity of the power. So that the velocity of the power to that of the weight will not be as the hypothenuſe to the perpendicular, as in the former caſe, but as the baſe to the perpendicular in the triangle A C B.

If the powers be increaſed juſt enough to overcome the friction of the plane and draw up the body W, let the pulley R be lifted up gradually to *r*, ſo as to keep the line W R parallel to itſelf till it comes to *w r*, and the power will be deſcended to *π*, when the weight is come to *w* B. But Π *π*, together with the diſtance R *r*, is equal to Π *ϖ*, or W Y, &c. And this traction, being conſtantly made in the angle W B T, is the caſe.

INCLINERS, or INCLINING DIALS. See the article DIALLING.

INCLOSURE, in huſbandry, the fence or hedge made to incloſe lands. See the articles FENCE and HEDGE.

A very good incloſure may be of made elder-ſticks, or truncheons, cutten or twelve feet long, and ſtuck into the bank ſlopewiſe, ſo as to make a chequer-work. Theſe make the ſpeedieſt ſhelter of any; and when the trees are grown up, they are valuable for the turner's uſe. They ſucceed extremely well in watery places; and when planted on the banks of rivers, they prevent them from being undermined by the current.

The throwing down incloſures is an offence puniſhable by our ancient ſtatutes; yet if the lord of a manor incloſes part of the waſte, and does not leave ſufficient room for the commoners, they may break down ſuch incloſures, or have a writ of aſſize.

INCOGNITIO, or INCOG, is applied to a perſon that is in any place where he would not be known: but it is more particularly applied to princes, or great men, who enter towns, or walk the ſtreets without their ordinary train, or the uſual marks of their diſtinction and quality.

INCOMBUSTIBLE, ſomething that cannot be burnt or conſumed by fire.

INCOMMENSURABLE, a term in geometry, uſed where two lines, when compared to each other, have no common meaſure, how ſmall ſoever, that will exactly meaſure them both. And in general, two quantities are ſaid to be incommenſurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal and ſide of a ſquare; for though each of thoſe lines have infinite aliquot parts, as the half, the third, &c. yet not any part of the one, be it ever ſo little, can poſſibly meaſure the other, as is demonſtrated in prop. 17. lib. x. of Euclid.

Rappus, lib. iv. prop. 17. ſpeaks alſo of incommenſurable angles. As to ſurfaces which cannot be meaſured by a common ſurface, they are ſaid to be incommenſurable in power.

INCOMMENSURABLE NUMBERS are ſuch as have no common diviſor that will divide them both equally.

INCOMPATIBLE, that which cannot ſubſiſt with another without deſtroying it: thus cold and heat are incompatible in the ſame ſubject, the ſtrongeſt overcoming and expelling the weakeſt.

INCORPOREAL, a thing, or ſubſtance, which has no body; as God, angels, and the ſoul of man.

INCORRUPTIBLE, that which cannot be corrupted.

INCORRUPTIBILES, or INCORRUPTICOLÆ, in church-hiſtory, heretics which had their original at Alexandria, in the time of the emperor Juſtinian. Their diſtinguiſhing tenet was, that the body of Jeſus Chriſt was incorruptible from his conception, by which they meant that after and from the time he was formed in the womb of his holy mother, he was not ſuſceptible of any change or alteration, not even of any natural and innocent paſſions, as hunger, thirſt, &c. ſo that he eat without any occaſion before his death, as well as after his reſurrection.

INCRASSATING, in pharmacy, &c. the rendering fluids thicker by the mixture of other ſubſtances leſs fluid; or by the evaporation of the thinner parts.

INCREMENT, and DECREMENT, the increaſe and decreaſe of a quantity. See the article SERIES.

INCRUSTATION, in ſurgery, the induction of a cruſt or eſchar upon any part.

Among maſons, incruſtation ſignifies the lining or coating of a wall, either with gloſſy ſtones, ruſtics, marble, pottery, or ſtucco-work, and that either equably or in panels and compartiments.

INCRUSTED, or INCRUSTATED COLUMN, is a column conſiſting of ſeveral pieces, or ſlips of ſome precious marble maſticated or cemented round a mould of brick, or other matter.

INCUBATION, the action of a hen, or other fowl brooding on her eggs.

INCUBUS, or EPHIALTES, in phyſic, commonly called the night-mare, a diſorder under which the patient cannot ſtir himſelf, but with the utmoſt difficulty; is ſeized with a numbneſs and ſenſe of weight, with a dread of ſuffocation, and an oppreſſion, as from ſome body falling ſuddenly upon him.

The word is derived from the Latin *incumbo*, in regard the patients fancy they feel ſomething aſcending and ſitting upon their breaſt.

This appears to be a diſeaſe of ſtricture, from the ſenſe of weight attending it; and of the chronical kind, from the length of time; and it is not always without danger, for ſome have died under the violence of the ſuffocation.

The incubus is of a bad kind, when it ſeizes the patient, though awake, in the night; but worſt of all, when, after moleſting him in his ſleep, it leaves him to awake under a cold ſweat and palpitation of the heart. Such as have been long and often ſubject to it, have reaſon to apprehend ſome dangerous diſtempers of the head, as a vertigo, apoplexy, &c.

The cure conſiſts in evacuations by phlebotomy and cathartics. The patient muſt be kept to a thin diet, and avoid all flatulent food.

INCUMBENT, a clerk, or miniſter, who is reſident on his benefice: he is called incumbent, becauſe he does, or at leaſt ought to bend his whole ſtudy to diſcharge the cure of his church.

INCURVATION *of the Rays of Light*, their bending out of a rectilinear or ſtraight courſe, occaſioned by refraction. See REFRACTION.

INCUS, in anatomy, a bone of the internal ear. See the article EAR.

INDEFEISIBLE, or INDEFEAZABLE, a term in law, for what cannot be defeated or made void; as an indefeiſible eſtate of inheritance, &c.

INDEFINITE, or INDETERMINATE, that which has no certain bounds, at leaſt aſſignable by the human mind.

Deſcartes uſes the word inſtead of infinite, in numbers and quantities, to ſignify a number ſo great, that an unit cannot be added to it; and a quantity ſo great, as not to be capable of any addition.

INDEFINITE, in the ſchools, alſo denotes a thing that has but one extreme; for inſtance, a line drawn from any point and extended infinitely, as alſo eternity *a parte ante*, or eternity *a parte poſt*.

INDEFINITE *Propoſition*. See the article PROPOSITION.

INDEFINITE, in grammar, implies ſuch nouns, pronouns, verbs, participles, &c. which are left in an uncertain indeterminate ſenſe, and not fixed to any particular time, or other circumſtance.

INDELIBLE, ſomething that cannot be cancelled or effaced.

INDEMNITY, in law, the ſaving harmleſs; or a writing to ſecure one from all damage and danger that may enſue from any act. An indemnity in regard to eſtates, is called a warranty. See the article WARRANTY.

Act of INDEMNITY, the ſame with act of grace. See *Act of* GRACE.

INDENTED, in heraldry, is when the out-line of an ordinary is notched like the teeth of a ſaw.

INDENTED LINE, in fortification, the ſame with what the French engineers call redent; being a trench and parapet running out and in, like the teeth of a ſaw; and is much uſed in irregular fortification. See FORTIFICATION.

INDENTED LEAF, among botaniſts, is one notched round its verge. See SERRATED.

INDEPENDENTS, a ſect of proteſtants in England and Holland, ſo called from their independency on other churches, and their maintaining that each church or congregation has ſufficient power to act and perform every thing relating to religious government within itſelf, and is no way ſubject or accountable to other churches or their deputies.

The preſent independents differ from the preſbyterians only in their church government, in being generally more attached to the doctrines diſtinguiſhed by the term orthodoxy, &c. and in adminiſtering the Lord's Supper at the cloſe of the afternoon's ſervice. See PRESBYTERIANS.

The ſeveral ſects of baptiſts are all independents with reſpect to church government.

INDETERMINATE, in general, an appellation given to whatever is not certain, fixed, and limited; in which ſenſe, it is the ſame with indefinite.

INDETERMINATE PROBLEM, in algebra, one which is capable of an indefinite number of ſolutions.

INDEX, in anatomy, the ſame with the fore-finger. See FINGER.

INDEX, in arithmetic and algebra, ſhews to what power any quantity is involved, and is otherwiſe called exponent. See EXPONENT.

INDEX *of a Logarithm*, that which ſhews of how many places the abſolute number belonging to a logarithm doth conſiſt; and of what nature it is, whether an integer or fraction. Thus, in this logarithm 2.523421, the number 2 ſtanding on the left hand of the point is called the index; becauſe it ſhews that the abſolute number anſwering to the above logarithm, conſiſts of three places: for the number is always one more than the index.

If the abſolute number be a fraction, then the index of the logarithm hath a negative ſign, marked thus $\bar{2}.523421$. See the article LOGARITHM.

INDEX *of a Globe*, the little ſtyle or gnomon, which being fixed on the pole of the globe, and turning round with it, points out the hours upon the hour circle. See the article GLOBE.

Expurgatory INDEX, a catalogue of prohibited books by the church of Rome.

INDIA PROPER, or HITHER INDIA, a large peninſu-

in Aſia, bounded on the north by Uſbec Tartary, and Thibet; on the eaſt, by another part of Thibet, the kingdom of Aſem, Ava, and Pegu; on the ſouth by the bay of Bengal, and the Indian ocean; and by the ſame ocean and Perſia on the weſt: ſituated between 66° and 92° of eaſt longitude, and between 7 and 40° of north latitude; being about 2000 miles in length from north to ſouth, and 1500 miles in breadth from eaſt to weſt, where broadeſt; though the ſouthern part of the peninſula is not 300 miles broad. All the country within theſe limits is either ſubject or tributary to the great Mogul. It is frequently called Indoſtan, a name ſuppoſed to be derived from the river Indus, on its weſtern frontiers: it is alſo called the Mogulſtan, from the imperial family now upon the throne, who trace their pedigree from Tamerlane, a Mogul Tartar.

The produce of this country, and what the Europeans import from thence, is chiefly chints, callicoes, muſlins, ſome ſilk, pepper, and diamonds, which are purchaſed by moſt nations with ſilver; but the Dutch frequently barter ſpices for them, which makes the India trade doubly advantageous to them.

INDIA beyond the Ganges, is a country bounded by Thibet and Boutan on the north; by China, Tonquin, and Cochin-China on the eaſt; by the Indian Ocean on the ſouth; and by the Hither India, the Bay of Bengal, and the Straits of Malacca on the weſt: it is ſituated between 92 and 104° of eaſt longitude, and between the equator and 30° degrees of north latitude: being near 2000 miles in length from north to ſouth; but of a very unequal breadth; in which limits are comprehended the kingdoms of Aſem, Ava, Pegu, Laos, Siam, Cambodia, and Malacca, governed by as many Indian princes; only the Dutch have uſurped the dominion of Malacca. In this country there are a vaſt number of elephants, and conſequently a great deal of ivory; our merchants alſo meet with gold and precious ſtones, canes, opium, and ſuch other articles as are uſually found within the tropics.

INDIAN BERRY, *Cocculus Indicus*, in commerce, &c. See COCCULUS.

INDIAN LEAF, *Malabathrum*, in botany, the leaf of a tree brought from the Eaſt-Indies. It is of a firm texture; of an oblong oval figure, pointed at both ends; ſmooth and gloſſy on one ſide, which is the upper, and leſs ſo on the lower; of a yelloviſh green colour on the former, and a pale browniſh on the latter; furniſhed with three ribs, running its whole length, very protuberant on the lower ſide, and two ſmaller ones which bound the edges.

Theſe leaves have a remarkable affinity, in one reſpect, with the caſia or bark of the tree of the cinnamon kind, both the leaves themſelves and their pedicles being, like it, extremely mucilaginous: chewed, they render the ſaliva ſlimy and glutinous: infuſed in water, they give out a large proportion of a ſtrong tenacious mucilage. But of the aromatic flavour, which is ſtrong in the bark, the leaves, as brought to us, have very little: they ſcarcely diſcover any warmth or pungency to the taſte, and have little or no ſmell, unleſs well rubbed, when they yield an agreeable, though weak, ſpicy odour. They are no otherwiſe made uſe of than as an ingredient in mithridate and theriaca; and are, when in their greateſt perfection, far inferior to the mace.

INDICATION, in phyſic, whatever ſerves to direct the phyſician how to act.

INDICATIVE, in grammar, the firſt mood, or manner, of conjugating a verb, by which we ſimply affirm, deny, or aſk ſomething; as, *amant*, they love; *non amant*, they do not love; *amas tu*, doſt thou love?

INDICATIVE *Column*. See COLUMN.

INDICTION, in chronology, a cycle of fifteen years. See CYCLE.

INDICTMENT, in law, is a bill or declaration of complaint, at the ſuit of the king, drawn up in form of law, and exhibited againſt a perſon, and afterwards preferred to the grand jury or inqueſt, who are to find whether the complaint be true or not. An indictment differs from an accuſation only in this, that the preferrer of the bill is not tied to the proof thereof, under any penalty, except there appear to be a conſpiracy.

INDIES, Eaſt and Weſt. See INDIA and AMERICA.

INDIGESTION, *Indigeſtio*, a want of due coction, either in the food, the humours of the body, or excrements.

INDIGNATORIUS MUSCULUS, a muſcle of the eye, otherwiſe called abducens, and rectus exterior: it has this appellation from its drawing the eye outwards, thereby occaſioning the appearance of ſcorn. See the article EYE.

INDIGO, in commerce, a preparation of the juice of a plant, whoſe leaves are ſmall, fleſhy, and ſoft, of a greeniſh brown colour on the upper-ſide, pale and as it were ſilver-coloured underneath. This plant, by ſome called anil, or nil, has ſeveral ſlender knotty ſtalks, which ſpread into ſmall branches, clothed each with from four to ten pair of theſe leaves, and an odd one at the end: it riſes to the height of about two feet, and produces reddiſh flowers, in ſhape reſembling thoſe of broom, but ſmaller, followed by oblong pods, containing the ſeeds.

Labat has given a particular account of the culture of the plant, and the preparation of the indigo. The ground being thoroughly cleared from weeds, one of the principal points in the culture, a number of ſlaves, ranged in a line, march acroſs, making little trenches of the width of their hoes, and two or three inches deep, about a foot diſtance from one another every way: then returning, they drop ſome ſeeds in each trench, and afterwards cover them with the earth taken out. In moiſt weather, the plant comes up in three or four days; and in about two months after, it is fit for cutting: if ſuffered to ſtand till it runs into flower, the leaves become too dry and hard, and the indigo obtained from them proves leſs in quantity, and leſs beautiful: the due point of maturity is known, by the leaves beginning to grow leſs ſupple, or more brittle. In rainy ſeaſons the cutting may be repeated every ſix weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford freſh crops for two years.

A large quantity of the herb is put into a vat or ciſtern of ſtrong maſon work, with ſo much water as is ſufficient to cover it, and ſome wood laid above to prevent its riſing up. The matter begins to ferment, ſooner or later, according to the warmth of the weather and the maturity of the plant, ſometimes in ſix or eight hours, and ſometimes not in leſs than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour inclining to violet. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpoſe, ſo as to be commanded by the firſt.

In the ſecond vat the liquor is ſtrongly and inceſſantly beat and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requiſite in hitting this point: if the beating is ceaſed too ſoon, a part of the tinging matter remains diſſolved in the liquor; if continued a little too long, a part of that which had ſeparated is diſſolved afreſh. The exact time for diſcontinuing the proceſs is determined, by taking up ſome of the liquor occaſionally in a little cup, and obſerving whether the blue fecula is diſpoſed to ſeparate and ſubſide.

The whole being now ſuffered to reſt till the blue matter has ſettled, the clear water is let off by cocks in the ſides at different heights; and the blue part diſcharged by a cock in the bottom, into another vat: here it is ſuffered to ſettle for ſome time longer; then further drained in cloth bags, and expoſed in ſhallow wooden boxes to the air, till thoroughly dry.

The author abovementioned, from whom the whole of the foregoing account is extracted, obſerves further, that the goodneſs of the indigo depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is leſs, but the colour proportionably more beautiful; that probably the ſecret of thoſe, whoſe indigo has been moſt eſteemed, is no other than cutting the herb at the time when it yields the fineſt colour; that the ſuperiority of ſome of the indigoes of the Eaſt-Indies to thoſe of America, is perhaps owing to the former being prepared more curiouſly from only the leaves of the plant; and that by beating the herb in the ſteeping vat, which has been practiſed by ſome with a view to increaſe the

quantity, great part of the ſubſtance of the leaves and bark is blended with the water along with the colouring matter, and the indigo extremely debaſed.

It is ſaid that lime or lime-water is ſometimes employed in the beating vat, to promote the ſeparation of the tinging particles from the water; and that the hardneſs or flintineſs of ſome ſorts of indigo is owing to an over-proportion of this addition.

Indigo is commonly divided, from the colour which it exhibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is ſaid that the dyers uſe chiefly the firſt; and the calico-printers, for this drug gives a durable ſtain to linen as well as woollen, the laſt. On what particular circumſtances theſe different appearances depend, we know not; nor is it certainly known, whether the real quality of the indigo has any connexion with them. The deepeſt and livelieſt indigo, rubbed with the nail, looks like poliſhed copper; and ſolutions of all the ſorts, made in alkaline lixivia, aſſume alike a copper-coloured ſkin upon the ſurface.

Good indigo is moderately light, breaks of a ſhining ſurface, and burns almoſt wholly away upon a red-hot iron. It is quickly penetrated by water, and reduced into a kind of paſte: a conſiderable part is at the ſame time diffuſed through the liquor, and very ſlowly ſubſides. This is probably what Labat and Hellot mean by its diſſolving in water; for no part of the indigo really diſſolves; it cannot indeed be expected that it ſhould from the proceſs by which it is obtained.

Indigo requires an equal quantity or more of fixed alkaline ſalt to render it totally ſoluble in water. On digeſting the indigo, with a gentle heat, in the ſolution of the alkaline ſalt, a ſhining copper-coloured ſkin begins to appear, and gradually covers the whole ſurface: on agitating the matter, a large blue flower or froth ariſes, and the liquor underneath appears of a deep green. If woollen cloth, without any other preparation than moiſtening it with warm water, be dipped in this hot liquor, it comes out perfectly green, and changes almoſt inſtantly in the air to a fine blue. This is the common proceſs of dying blue.

Mr. Hellot deſcribes two indigo vats with urine; one of which is uſed hot like the foregoing, and the other cold. The hot vat conſiſts of equal parts of indigo, alum, and tartar, digeſted in urine till the liquor becomes green. The cold one is prepared, by digeſting powdered indigo with vinegar for twenty-four hours, in the proportion of four pounds to about three quarts; then mixing the matter with about fifty gallons of urine, and ſtirring the whole together every night and morning, till the liquor turns green, and gathers a head like the common vat.

Indigo is fitted for printing on linen, by diluting it with water into the conſiſtence of a ſyrup; then adding ſome powdered pearl-aſhes, green vitriol, and lime newly ſlaked; with ſo much water, occaſionally, as will reduce them into the conſiſtence of thin paint; mixing the whole thoroughly together, and ſtirring the matter every now and then, till it gains a copper-colour on the ſurface. The proportions uſed by the workmen are, two parts of indigo, one of pearl-aſhes, three of vitriol, and two of lime.

The ſame compoſition, diluted with a ſufficient quantity of water, about ſix gallons to a pound of indigo, and boiled, gives a durable blue to tanned ſkins, whether dipped in hot or cold.

Indigo, digeſted in a moderate heat, with different volatile alkaline ſpirits, gave only yelloviſh and browniſh red tinctures; with rectified ſpirit of wine, a reddiſh one: to lime-water, and to water acidulated with the vitriolic, nitrous, and marine acids, it gave no tincture at all.

The concentrated vitriolic acid unites with it into a ſmooth paſte, eſpecially if the indigo is previouſly well ground with powdered glaſs, ſand, or other like ſubſtances; the indigo is thus rendered ſoluble in boiling water along with the acid, ſo as to paſs through the pores of a filter: the ſolution, whilſt hot, appears of a deep bright green colour, like that made by fixed alkalies, but fades as it grows cold, and changes at laſt to a browniſh.

Theſe experiments, which were many times repeated with the ſame event, ſeem to overturn Mr. Hellot's ingenious theory; which deduces the green colour of ſolutions of indigo, from the common property of blue juices of being turned green by the alkalies; and the blue colour which the cloth acquires ſoon after it is taken out of the vat, from a ſeparation of the alkali. We here find, that a green ſolution of this concrete is obtainable by the ſtrongeſt of the acids, and that with volatile alkalies it diſcovers no tendency to greenneſs.

The ſolution of indigo in oil of vitriol does not appear green till boiled. The thick compound, dropped into water no hotter than the hand can bear, communicates a bright blue colour: woollen cloth or ſilk, prepared with alum and tartar, acquire from this liquor the beautiful but periſhable blue dye, called Saxon blue. The Saxon green is dyed, by dipping the ſtuff a ſecond time in the yellow decoction of fuſtick; or more compendiouſly, by mixing the acid blue compoſition with that decoction at once, till the liquor has gained the depth of colour required.

It is ſaid that the dyers of Norwich, who purchaſed this ſecret from Saxony, prepare the blue compoſition by grinding nine parts of indigo with twenty of red arſenic; then adding to them, in a glazed veſſel, forty-eight parts of oil of vitriol, and ſtirring them well together: after the mixture has ſtood for twenty-four hours, it is fit for uſe. In Mr. Hellot's proceſs, received likewiſe from Germany, the proportions are ſomewhat different; and inſtead of red arſenic, cobalt and orpiment are uſed. Theſe differences are immaterial: the only uſe of the additional matter ſeems to be, to divide the indigo, and render it more eaſily miſcible with the acid. It will ſucceed, in ſmall ſpecimens, with red and with white arſenic, with orpiment and with cobalt, with ſulphur, with antimony, with powdered glaſs, with powdered ſand, and with flint.

The indigo, in the diluted blue liquors, is perfectly diſſolved, ſo as to paſs through a filter. The ſolutions, haſtily evaporated to the conſiſtence of a ſyrup, become turbid and green. On ſlow evaporation, they continue uniform and blue, and readily mingle again with freſh water, paſſing the filter as before, of a fine blue colour.

INDIVIDUAL, *Individuum*, in logic, a particular being of any ſpecies, or that which cannot be divided into two or more beings equal or alike.

INDIVISIBLE, among metaphyſicians. A thing is ſaid to be indiviſible abſolute, abſolutely indiviſible, that is a ſimple being, and conſiſts of no parts into which it may be divided. Thus God is indiviſible in all reſpects, as is alſo the human mind, not having extenſion or other properties of body.

INDIVISIBLE *Secundum quid eſt*, indiviſible with reſpect to what it now is, a ſubſtance which, though it conſiſts of parts into which it may be divided, yet never can be ſo divided as to remain the ſame: thus a meaſure or number is ſaid to be indiviſible, for if from a foot-line, for example, any thing is deducted, it is no more a foot-line; and if from the number three any thing is ſubſtracted, it is no longer the ſame number. See the next article.

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately reſolved; which elements are ſuppoſed infinitely ſmall: thus a line may be ſaid to conſiſt of points, a ſurface of parallel lines, and a ſolid of parallel and ſimilar ſurfaces; and then, becauſe each of theſe elements is ſuppoſed indiviſible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the ſame as the number of the elements; whence we may ſee that a parallelogram, priſm, or cylinder, is reſolvible into elements or indiviſibles, all equal to each other, parallel and like to the baſe; a triangle into lines parallel to the baſe, but decreaſing in arithmetical proportion, and ſo are the circles which conſtitute the parabolic conoid, and thoſe which conſtitute the plane of a circle, or ſurface of an iſoſceles-cone. See the article INFINITESIMALS.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received. See the article BILL.

INDUCEMENT, in law, ſignifies what may be alledged as a motive; and, in our law, it is uſed ſpecially in ſeveral caſes; as, there is an inducement to actions, to a traverſe in pleading, and to an offence committed, &c.

IN-

INDUCTION, in law, is putting a clerk or clergyman in poſſeſſion of a benefice or living to which he is collated or preſented. See PRESENTATION.

INDULGENCES, in the Romiſh church, are a remiſſion of the puniſhment due to ſins, granted by the church, and ſuppoſed to ſave the ſinner from purgatory. Clement VI. in his decretal, which is generally received by the church of Rome, declares, that our Saviour has left an infinite treaſure of merits, ariſing from his own ſufferings, beſides thoſe of the bleſſed virgin and the ſaints; and that the paſtors and guides of the church, and more eſpecially the popes, who are the ſovereign diſpoſers of this treaſure, have authority to apply it to the living, by virtue of the keys, and to the dead, by way of ſuffrage, to diſcharge them from their reſpective proportions of puniſhment, by taking juſt ſo much merit out of this general treaſure, as they conceive the debt requires, and offering it to God.

It was the great abuſe of indulgences that contributed not a little to the firſt reformation of religion in Germany, where Martin Luther began firſt to declaim againſt the preachers of indulgences, and afterwards againſt indulgences themſelves: for ſince that time the popes have been more ſparing in the exerciſe of this power; however, they ſtill carry on a great trade with them in the Indies, where they are purchaſed at two reals a piece, and ſometimes more.

INDULT, in the church of Rome, the power of preſenting to benefices granted to certain perſons by the pope.

INDULTO, a duty, tax, or cuſtom paid to the king of Spain, for all ſuch commodities as are imported from the Weſt-Indies in the galleons. See the article GALLEONS.

INERTIA *of Matter*, in philoſophy, is defined by Sir Iſaac Newton to be a paſſive principle by which bodies perſiſt in their motion or reſt, receive motion in proportion to the force impreſſing it, and reſiſt as much as they are reſiſted. It is alſo defined by the ſame author to be a power implanted in all matter whereby it reſiſts any change endeavoured to be made in its ſtate.

This power then coincides with the *vis reſiſtendi*, or power of reſiſting, whereby every body endeavours, as much as it can, to perſevere in its own ſtate, whether of reſt or uniform rectilinear motion; which power is ſtill proportionable to the quantity of matter in any body: for ſince natural bodies conſiſt of a maſs of matter, that, of itſelf, is not able to induce any change in its ſtate, if bodies were once at reſt, it is neceſſary that they ſhould always remain in that ſtate of reſt, unleſs there is applied a new force to produce motion in them: but if they were in motion, the ſame energy or force would always preſerve the motion; and therefore bodies would always retain their motion, and would always proceed forward in the ſame right line with the ſame tenor, ſince they cannot of themſelves acquire either reſt or a retardation, or a change of their direction to turn on one ſide or the other.

There are ſome philoſophers who readily enough acknowledge, that no body can move of itſelf, that is, paſs from reſt to motion of itſelf, but then they are not as willing to grant, that bodies once moved cannot of themſelves arrive at reſt, by reaſon they ſee the motions of projectiles languiſh by degrees, and at laſt the moving bodies themſelves come to reſt. See the article PROJECTILES.

But as no mode or accident can of its own accord, or by itſelf, be deſtroyed, and as all effects produced by tranſient cauſes do remain always, unleſs there be ſome new and extraneous cauſe that deſtroys them; ſo likewiſe motion once commenced, will be continued always, unleſs it be hindered by ſome external cauſe: nor is it more in the power of a body once moved, to lay aſide its motion or energy to move, and return of itſelf to reſt, than it can put off the figure that it has been once formed into, and acquire a new one, without ſome extrinſic cauſe. Therefore, there is in all bodies a certain force, or rather inactivity, whereby they oppoſe every change; from which cauſe it proceeds, that they are very difficultly put out of their ſtate, whatever it is: but that inactivity is the ſame in moving bodies as in thoſe at reſt, nor do bodies leſs reſiſt the action, whereby they are brought from motion to reſt, than that whereby they paſs from reſt to motion; that is, there is not required a leſs force to put a ſtop to the motion of any body, than was before neceſſary to impreſs that motion on the ſame body. Whence ſince the *vis inertiæ*, or inactivity of matter, always equally reſiſts equal changes, it will not be leſs powerful to continue a body in motion, which has begun to move, than to preſerve a quieſcent body in the ſame ſtate of reſt.

There are ſome philoſophers who ſuppoſe body of its own nature to be as indifferent to motion as to reſt; but by this indifference they do not, we ſuppoſe, mean ſuch a diſpoſition in bodies, whereby they do not in the leaſt reſiſt reſt or motion: for on this ſuppoſition it would follow, that any body, however great, and moved with the ſwifteſt velocity, might be ſtopped by any the ſmalleſt force; or if the great body was at reſt, it might be moved by any body, however ſmall, without the leaſt loſs of velocity in the impelling body: that is, any ſmall body impinging on a greater one, would carry that greater body along with it, without the leaſt loſs of its motion; and each body after the impulſe, would be jointly carried along with that celerity that the ſmall body had at firſt, which we all know is abſurd. This indifference, therefore, is not placed in a non-reſiſtance to motion from a ſtate of reſt, or to reſt from a ſtate of motion; but in this only, that a body of its own nature is not more propenſe to motion than to reſt, nor more reſiſts to paſs from a ſtate of reſt to motion, than to return again from that motion to the ſame ſtate of reſt: beſides, any quieſcent body may be moved by any force; and an equal force, acting in a contrary direction, will be able to deſtroy that motion; and in this, this indifference conſiſts.

Since, according to this law, a body once in motion always continues in that motion, the philoſophers aſk, Why all projectiles loſe by degrees their motion? Why do they not proceed in infinitum? If motion did not of its own nature decay, a ſtone thrown at the beginning of the world, would by this time have gone through an immenſe and almoſt infinite ſpace. And ſo indeed it would, if its motion had been in vacuo, or in free ſpaces, and without any gravity. But ſince all projectiles are carried either through the air, or on the rough ſurfaces of other bodies, they muſt be neceſſarily retarded: for ſince all bodies in motion muſt drive and thruſt out of its place the reſiſting air, or overcome the roughneſs of the ſuperficies upon which they are moved, they will loſe all that force and motion that is conſtantly employed in overcoming theſe obſtacles, and conſequently the motion of projectiles will be continually diminiſhed: but if there was no reſiſtance in the medium, no roughneſs in the ſuperficies on which they were moved, no gravity that continually forces the bodies towards the earth, motion would always continue the ſame, without any retardation at all. So in the heavens, where the medium is exceedingly rare, the planets do continue their motions for a very long time; and upon ice, or any other very ſmooth ſurface without any roughneſs, heavy bodies in motion are not ſoon brought to reſt.

INFALLIBLE, what cannot deceive, nor be deceived.

The word is Latin, and formed of *in*, taken privately, and *fallo*, to deceive.

INFAMOUS, in general, denotes ſomething notoriouſly contrary to virtue or honour.

The word is derived from the Latin *in*, and *fama*, report.

INFAMOUS, in law, denotes a perſon of no repute in the world. There are two kinds of infamy; ſome perſons being infamous *de jure*, or ſtigmatized by public judgments: others are infamous *de facto*, as being of a ſcandalous profeſſion, as a catchpole, hangman, informer, &c.

INFANT, *Infans*, in medicine, denotes a young child. See the articles CHILD and DELIVERY.

The diſeaſes incident to little children, and thoſe newly born, are the thruſh, pukings, coughs, watchings, ſtartings, inflammations of the navel, runnings of the ears, and gripes. When they begin to breed teeth, troubleſome itchings of the gums, fevers, convulſions, diarrhœas happen, eſpecially when they put forth the canine teeth,

and

and in thoſe particularly who are very groſs and inclinable to be coſtive. When advanced from two to ten years and longer, they labour under inflammations of the tonſils, inward luxations of the vertebra next the head, aſthmas, ſtone, round belly-worms, aſcarides, penſile warts, ſatyriaſes, ſtranguries, ſcrophulous tumors, and other tubercles.

Of all the afflictions which torture tender infants, violent pains of the abdomen and inflations moſt frequently occur. The principal intention of the phyſician, in order to cure theſe, is to abſorb, correct, and gently evacuate the corroſive acid of the primæ viæ. If the diſorder, as it generally happens, ariſes from vitiated milk, the nurſe is either to be changed, or care muſt be taken that ſhe do not at that time indulge herſelf with flatulent food; and gentle laxatives, if ſhe be coſtive, are proper for the nurſe. Among theſe, the preparations of rhubarb are the moſt eligible; nor are carminative medicines leſs beneficial to the nurſe. But nothing relieves infants more than clyſters and the internal exhibition of preparations of rhubarb, as alſo a ſcruple of aniſeed groſly pounded, if given with the firſt ſpoonful of ſugared-pap.

If there be a ſuſpicion of worms, it is proper to give the remedies accommodated to kill and diſlodge theſe hoſtile animals. External remedies ſhould alſo be applied againſt the violence of this diſorder, as emollients.

Epilepſies and convulſions are generally more incident to childhood, which continues from the firſt to the ſeventh year, becauſe, in infants, the nervous, membranous, and exquiſitely ſenſible parts conſiſt of very tender and very moveable ſmall fibres, which being irritated, though in the ſlighteſt manner, are very eaſily thrown into ſpaſmodic commotions.

If this diſorder take its riſe from a fright or violent paſſion of the nurſe, it is proper to give what gently curbs the inordinate and ſpaſmaſtic motions of the nervous ſyſtem, ſuch as emollient and carminative clyſters, and antiſpaſmodic powders either exhibited alone, or in ſome water of a ſedative quality. If it ariſe from the milk rendered corroſive in the infant, beſides demulcent clyſters, abſorbent powders exhibited with ſaffron, muſk, or a ſmall quantity of the extract of caſtor, are of ſingular ſervice, eſpecially if a pretty rich decoction of harts-horn be uſed for drink: but if the primæ viæ are to be purged, this end is anſwered by a decoction impregnated with manna, ſucceſſively exhibited with a few drops of the oil of tartar per deliquium dropped into it. If the diſorder proceeds from too large a quantity of groſs milk, the infant ſhould be fed with leſs, and ſuch aliments given, as render it more fluid. Likewiſe a third or fourth part of a grain of emetic tartar, mixed with ſyrup of violets and ſome proper diſtilled water, is often ſerviceable, when given out of the paroxyſm. When the meconium produces this diſorder, it ought to be evacuated by gentle laxatives mixed with abſorbents. If an epilepſy proceed from a repulſion of the itch, a ſcald head, &c. thoſe things ſhould be uſed which may recal the impure matter to the ſurface of the body, and veſicatories applied to the nape of the neck, have been found very beneficial.

As to an atrophy in children, where there is a gradual conſumption of the whole body, attended commonly with an inflation of the abdomen, and an extraordinary injury of the ſeveral functions, we are, in general, to take care, that, after weaning, they be ſupplied with food of ſuch a kind, as adds nutriment and ſtrength to the emaciated body, as broths of bruiſed fowls, or capons prepared without the fat, paps of apples prepared with the yolks of eggs and ſugar, together with a little cinnamon, mace, and wine. When obſtructions happen in the mouths of the lacteals, proper deobſtruents are to be uſed.

A cardialgia in children principally diſcovers itſelf by an uncommon ſtraitneſs over the breaſt, joined with difficult reſpiration, by inflations of the abdomen and præcordia, by inquietudes and eructations; to which ſlight fevers and convulſions are frequently joined.

During the fit, but little milk ſhould be given the infant, and antiſpaſmodic abſorbent powders, with ſome carminative water, ſhould be adminiſtered both to the nurſe and infant: and for their drink, gelatinous decoctions of the harts-horn and correcting emulſions. To diſcharge the flatulencies, gently carminative and emollient clyſters ſhould be given: an outward application of paregorics is likewiſe very beneficial.

After the fit, in order to remove the ſomes of the diſtemper, not only the nurſe, but alſo the infant ought to be gently freed from the ſordes lodged in the ſtomach and inteſtines, not omitting at the ſame time the uſe of corroborating and ſtomachic medicines.

To cure the iſchury or retention of urine in children, the nurſe, while ſhe gives ſuck, and the infant, when weaned, muſt avoid all improper aliments and unwholeſome drinks: but if the diſorder be ſupported by an obſtructed evacuation by ſtool, reſins impregnated with rhubarb ſhould be taken in proper aliments, or clyſters ſhould be duly injected. When the diſcharge of urine is ſuppreſſed by calculous fragments obſtructing the urethra, emollient clyſters are in like manner of ſervice. Internally antiſpaſmodics ſhould be adminiſtered; and externally baths, in which emollient ſubſtances have been boiled, are highly beneficial; as alſo bags fitted with the ſame things applied warm to the region of the pubes, the anointing which with the oil of ſcorpions is alſo productive of happy effects.

For the cure of a cough and aſthma in infants, abſorbent powders, the root of Florentine orris, ſpermaceti, and ſugar-candy, internally exhibited, are highly beneficial, and all the methods uſed whereby tranſpiration may not only be promoted, but a reſolution of the inſpiſſated fluids commodiouſly obtained.

If an aſthma attended with a cough, proceed from acid and viſcid crudities in the ſtomach, a mild emetic is often ſucceſsful, and this end is likewiſe very well anſwered by emollient and carminative clyſters. If a repelled, acrid, and excrementitious matter give birth to the diſorder, beſides internal diaphoretics, gentle veſicatories, applied to the nape of the neck, often produce a happy effect.

For ulcerous tubercles and catarrhous defluxions, ſuch infuſions ſhould be exhibited to the nurſe as dilute the blood and lymph; the infant ſhould have laxatives adminiſtered. Inflammations of the parotid glands are, beſides the internal uſe of reſolvents, to be treated externally with the ſimple diachylon plaſter, mixed with camphire; and, if the tumor cannot be diſcuſſed, it is to be maturated by emollient cataplaſms.

As to the cure of hiccups and vomitings in infants, if milk taken plentifully offend, its quantity ought to be leſſened; but if the diſorder proceed from its depraved quality, we ought to procure a proper excretion of it both from the nurſe and infant.

As to coſtiveneſs in children, the nurſe ſhould uſe a light and reſolving diet, exhibiting, at intervals, currants, either in the form of an electuary, with rhubarb and ſugar, or boiled with apples. But the infant is relieved either by ſyrup of ſuccory with rhubarb, and a few grains of white mechoacan at proper intervals, or clyſters of a decoction of oats with honey and butter, or of whey and Venice ſope. The navel ſhould alſo be anointed with oil of ſweet almonds, mixed with a due quantity of the trochiſci alhandal, reduced to powder.

A diarrhœa or exceſſive flux ought not to be ſuddenly checked, eſpecially if children bear it well, and if its ſuppreſſion be not indicated as proper. But when this happens, we muſt have a regard to the nurſe's milk, and if ſhe lay a foundation for the diſtemper, ſhe muſt be changed, uſing at the ſame time a proper ptiſan. The diſordered infant may be relieved by taking internally powders of Armenian bole and crabs-eyes, with a few grains of the bark of caſcarilla, to which may be added, as circumſtances require, amber and a third part of the theriaca cæleſtis for a doſe; and externally the belly is to be anointed with a proper liniment. And beſides theſe, in ſuch a ſtate of the diſeaſe, great advantages accrue from the uſe of clyſters. *Hoffman.*

INFANT, in law, ſignifies a perſon under the age of one and twenty.

INFANTE and INFANTA, all the ſons and daughters of the kings of Spain and Portugal, except the eldeſt; the princes being called infantes, and the princeſſes infantas.

INFANTRY, in military affairs, denotes the whole body of foot-ſoldiers. See the articles FOOT and SOLDIERS.

INFECTION, among phyſicians, the ſame with contagion. See CONTAGION.

INFERNAL-STONE, *Lapis infernalis*. See the article LAPIS.

INFINITE, that which has neither beginning nor end: in which ſenſe God alone is infinite. See the article GOD.

Infinite is alſo uſed to ſignify that which has had a beginning, but will have no end, as angels and human ſouls. This makes what the ſchoolmen call *infinitum a parte poſt*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end but had no beginning.

INFINITE, in mathematics, are ſuch quantities as are either greater or ſmaller than any aſſignable one, being the ſame with indefinite or indeterminate, to which no certain limits are preſcribed.

The doctrine of infinites has given occaſion for many diſputes; but the true ſtate of the caſe is this: So long as we reaſon upon wrong ſuppoſitions, we muſt never expect to arrive at truth; but the nearer our ſuppoſitions are to truth, the nearer will be the concluſion; and if theſe ſuppoſitions be infinitely near the truth, the errors in the concluſion will be infinitely ſmall, which being at laſt thrown out of the account, the concluſion will be the ſame as if we had proceeded upon principles accurately true. This is the true riſe of infinitely ſmall quantities in all mathematical computations, and the true reaſon for rejecting them, when the operation is over; but it may be reaſonably demanded, How do we know that theſe infinitely ſmall errors in the concluſion ariſe from ſimilar errors in the premiſes? And the anſwer is, becauſe theſe two ſorts of errors have ſo mutual a dependence one upon another, that one cannot be made to vaniſh, but the other will neceſſarily vaniſh with it. If it be further demanded, What the wrong ſuppoſitions are from which theſe infinitely ſmall errors ſpring? I anſwer, in the firſt place, the ſuppoſing magnitudes to have quantity, which in reality have none at all, but have entirely loſt it, either by running into infinity on the one hand, or into nothing on the other. Thus, if we ſuppoſe the point D to actually coincide with the angular point C (plate LXXVI. *fig.* 3.) the line DC will not only comparatively, but abſolutely be equal to nothing; that is, it will be no line at all, nor can any uſe be made of it: but by allowing the ſaid line to have ſome quantity, though extremely ſmall, or leſs than any that can be aſſigned, we tacitly ſuppoſe the point D not to be actually in the angular point C, but infinitely near it.

A quantity, after it is reduced to nothing, ceaſes to be a quantity; and if 0 have no quantity, neither can its reciprocal $\frac{1}{0}$, or any magnitude expreſſed by it, be ſaid to have any: but the reciprocal of nothing ſignifies a magnitude infinitely great in the ſtricteſt ſenſe of the word, and can no more be ſaid to have quantity than abſolute nothing can; and to compare ſuch magnitudes in reſpect of their quantity, which actually have none, is contrary to the definition both of ratios, and the object of proportion: nay, I know not whether the greateſt part if not all the difficulties that are ſaid to attend the idea of infinity, and our inability to comprehend it, ought not rather to be charged upon the abſurdity of comparing things together which in their own natures are incapable of all compariſon. It is ſaid indeed that infinite parallelopipeds, ſtanding perpendicular upon finite baſes, and upon the ſame plane, are in proportion as their baſes; which is true; but this is not comparing magnitudes in reſpect of the quantity they have not, but in reſpect of the quantity they have; one of theſe parallelopipeds may be ſaid to be broader or thicker than another, though not higher. Thus, if r be any quantity whereof the multiples $2r$ and $3r$ are taken, $2r$ may be ſaid to be to $3r$ as 2 to 3, whether r be finite or infinitely great or ſmall; nay, though r ſhould ſignify an impoſſible quantity; as $\sqrt{-1}$, $\sqrt{-2}$, &c. But then the quantity of this proportion does not depend upon the quantity r, but upon the coefficients 2 and 3: but I muſt here take notice however, that if r be actually infinite, I mean in the ſtricteſt ſenſe of the word, by $2r$ and $3r$ muſt then be meant, not quantities twice or thrice as big as r, in the ſame reſpect wherein it is infinite, but twice or thrice taken, which is no way abſurd; for if it be poſſible for any one infinite quantity to exiſt, that is not every way infinite, it will be as poſſible for others to exiſt of the ſame kind, independently of the former: a parallelopiped, that is infinitely extended only as to its length, and that both forwards and backwards, may however receive any addition, or be increaſed or diminiſhed in any proportion in reſpect of its finite dimenſions, but not in reſpect to its infinite dimenſions; and this is all the proportion I can conceive infinite quantities capable of. See *Philoſophical Tranſactions*, N°. 195.

That lines or quantities may continually decreaſe, and yet never become nothing, may be eaſily ſhewn in the following manner.—Let MCLK (*fig.* 4.) be an indefinite right line, P a given point out of that line; from P draw PCB perpendicular to MCLK, and of any length at pleaſure; from P draw PE, PF, PI, &c. obſerving always to make the ſegments DE, TF, LI, &c. of thoſe lines conſtantly equal to CB: from the points E, F, I, &c. let fall upon MCK the perpendiculars EG, FH, IK, &c. It is very evident that each following perpendicular is ſhorter than any of the preceding ones; and it is as evident, that were the number of them ever ſo great, the laſt perpendicular would be of a finite length, becauſe its correſponding hypothenuſe does, by the hypotheſis, form a finite angle with the indefinite line MCLK, and does alſo conſtantly riſe above it.

Mathematicians, and more eſpecially thoſe who underſtand this ſubject, are, generally ſpeaking, reſerved enough upon it, and chuſe rather to be deficient than redundant in their expreſſions upon theſe occaſions; not from any diffidence in their own principles, but knowing very well how liable matters of this nature are to be drawn into diſputes by ſuch as lie upon the catch, and make it their chief buſineſs to oppoſe the truths which they themſelves could never have diſcovered, nor perhaps will ever be able to underſtand.

INFINITE *Series*. See SERIES.

INFIRMARY, a kind of hoſpital, where the weak and ſickly are properly taken care of. See the article HOSPITAL.

INFLAMMABILITY, that property of bodies, which diſpoſes them to kindle, or catch fire. See the articles FIRE, FLAME, HEAT, &c.

INFLAMMATION, in ſurgery and medicine, is defined to be a preſſure and attrition of the red arterial blood, ſtagnating in the ſmalleſt canals, produced by the motion of the reſt of the blood, thrown into a violent and forcible commotion, by means of a fever. See the article FEVER.

This definition of an inflammation is taken from its cauſes. Others define it from its ſymptoms to be a ſpecies of tumour attended with a burning heat, pain, redneſs, reſiſtance, and a continual pulſation and pricking. See TUMOUR.

Inflammations are either external, being ſuch as fall properly under the buſineſs of ſurgery, and are cured by manual operations and topical remedies; or internal, being ſuch whoſe cure is to be expected chiefly from the uſe of internal remedies.

General Diviſion of external INFLAMMATIONS. External inflammations, ſeated in the common integuments, are generally termed phlegmons; but when ſlighter, they are called furuncles. The inflammation which is not fixed deep, but only ſpreads ſuperficially on the ſkin, is uſually diſtinguiſhed by the name of an eryſipelas; and the inflammatory tumour that ariſes at the finger-ends, is termed paronychia; when the inflammation fixes in the groin or armpits, the tumour is called a bubo; when under the ears, parotis. If an inflammation ſeizes the hands and feet from extreme cold, chilblains ariſe: other inflammations have alſo particular names, according to the particular part of the body they poſſeſs.

General Cauſes of external INFLAMMATIONS. The cauſe of a phlegmon, or an external inflammation, ariſes generally from too thick or viſcid a ſtate of the blood, ſtagnating in the anaſtomoſes of the ſmalleſt arteries and veins; ſo that the blood being ſent in larger quantities than it can paſs through thoſe veſſels, muſt of conſequence excite the fore-mentioned general ſymptoms of an inflammation, and muſt occaſion great diſorders at every part where ſuch ſtagnation is made. And though no part of the body, whether external or internal, nor the bones

themſelves are exempt from this kind of inflammation, yet it more frequently happens in the fat and glands than any where alſe.

With regard to the cauſe whence that inſpiſſation and ſtagnation in thoſe veſſels proceeds, they are, according to Heiſter, of two kinds, of which the firſt may be called external, and the latter internal. Among the external cauſes are placed in the firſt rank all wounds, fractures, luxations, contuſions, punctures by thorns and ſplinters, with a too great compreſſion of the veſſels, whether by too ſtrict a bandage, or otherwiſe. To theſe cauſes may be added burns of all ſorts, extreme cold, too violent a motion of the body; the external or internal application of too ſharp and ſtimulating ſubſtances, ſticking plaſters, oily and fat things, with abundance of the like nature, which ſtop up the pores of the ſkin, and impede the free courſe of the blood.

Among the internal cauſes, the ſame author reckons any thing acrimonious in the fluids, as in the ſcurvy; as alſo from the blood's abounding in too great quantities, or being of too thick a conſiſtence; or laſtly, when it circulates in the body with too violent a motion: for by this means the groſſer particles of the blood are drove, and, as it were, wedged into ſmaller veſſels, than they can readily find a paſſage through, and this, more eſpecially, when a ſudden cold is ſpread over a body that is in a great heat. In ſhort, every thing will produce an obſtruction which makes the parts of the blood too groſs and bulky, or too much contracts the mouths of the ſmall veſſels.

General Criſes and Cure of INFLAMMATIONS. Inflammations terminate variouſly, according to their different degrees of violence, the cauſes from whence they ariſe, the parts which they affect, and the particular conſtitution of the patient, with ſeveral other circumſtances which alſo preſage to us what ſhall be the end of the inflammation. But the ſeveral ways wherein an inflammation terminates are chiefly four. It is either 1. ſo diſperſed and reſolved as to vaniſh without leaving any conſiderable injury in the part affected, and which afterwards recovers its former vigour, and is of all others, the beſt courſe it can take; or elſe, 2. the inflammation ſuppurates, and degenerates into an abſceſs, ſo as to leave ever after ſome damage in the organ; or elſe, 3. the inflammation degenerates into a gangrene, or ſphacelus; or laſtly, into a hard tumor, commonly called a ſcirrhus, which grows more compact in the part affected, as the inflammation remits or goes off.

As to the reſolution and diſperſion of an inflammation, that is uſually practicable, where it is only of a milder kind, in a ſound habit of body, when the blood is not yet too viſcid nor vehement in its motion. See the article DISPERSION.

But ſuppuration follows, when the inflammation is more violent, the circulation more rapid, but yet the maſs of blood ſomewhat temperate, and without much acrimony: the treatment of an inflammation that terminates in a ſuppuration, the reader will find delivered under the articles SUPPURATION, ABSCESS, &c.

When the forementioned ſymptoms are much more violent, and when the blood is at the ſame time more acrimonious and rapid than it ought to be, the inflammation generally terminates in a gangrene. See the article GANGRENE.

But if the inflamed part be full of glands, and the blood very thick, glutinous, and inſpiſſated, the ſmall blood veſſels are then ſo ſtrongly ſtuffed up with glutinous blood, that they are compacted together, the parts loſe their ſenſation, and are converted into a hard tumour, which is thence called a ſcirrhus. See the article SCIRRHUS.

INFLAMMATION *in the Breaſts*, a diſorder moſt incident to child-bearing women, and almoſt conſtantly happens in a few days after their delivery.

If the milk ſhould be propelled too plentifully and forcibly into the breaſt, which at ſuch times frequently happens; and if the mother ſhould then be ſeized with cold, fear, anger, or a ſudden perturbation of mind, the ſanguiferous and lactiferous veſſels being thence obſtructed, the breaſts muſt then become inevitably tumified, which will be attended with great heat, redneſs, reſiſtance, and violent pain. The ſame accident often happens to women that give ſuck even a long time after their lying-in, and is ſometimes the caſe of thoſe who have no milk, all proceeding from the cauſes already mentioned; and Heiſter gives us an inſtance of a man's breaſt being inflamed by means of a great fright. Theſe inflammations do not, according to that author, always happen to be equally intenſe and violent; for ſometimes it ſeizes the whole breaſt; ſometimes only one ſide; and at other times occupies only a ſmall part of the breaſt: ſometimes the inflammation lies very near the ſkin; at other times very deep; and at one time it has urgent ſymptoms, and at another, it ſits eaſy on the part.

This diſorder may be ſpeedily removed in women of condition, and ſuch as do not ſuckle their children, if ſome of the plaſter of ſperma ceti ſpread on linnen be applied warm all round the breaſt ſoon after parturition; being perforated in the middle, to tranſmit the papilla or nipple; the acceſſion of the milk being alſo repelled by a very ſtrait bandage. Among the internal remedies, the moſt proper are ſuch as bring down the lochia puerperarum, when they do not flow in ſufficient plenty of themſelves: the principal remedies for this purpoſe are the eſſence of myrrh, amber, the eſſence of ſaffron, elixir proprietatis, &c. Laſtly, with reſpect to the proper drink, it muſt be carefully obſerved to diminiſh the quantity of milk by the ſmallneſs and poverty of the meat and drink, upon which account the patient ſhould be recommended to drink ſmall broth, tea, or the like watery liquors: and if the mother be deſirous of ſuckling the infant, there can be no better preſervative againſt the inflammations of the breaſts. But when the inflammation is fixed, the cure muſt be attempted either by diſperſion or ſuppuration, for the method of which ſee DISPERSION and SUPPURATION.

But if it happens that the tumour will neither yield to diſperſion nor ſuppuration, and is in danger of turning to a ſcirrhus, or cancer, the patient muſt be kept in good ſpirits, and the plaſter of ſperma ceti be conſtantly retained on the tumour, by which means it will probably either grow leſs, or elſe vaniſh.

INFLAMMATION *of the Bladder*, that attended with an acute, burning, preſſing pain, in the region of the pubes, a fever, and a continual teneſmus, or deſire of going to ſtool, and a perpetual ſtriving to make water.

Other ſymptoms of this diſeaſe are a rumbling of the bowels, griping pains, great anxiety of the præcordia, difficult breathing, want of appetite, and vomiting, coldneſs of the extreme parts, a hard, quick, unequal, contracted pulſe, inquietude, and ſometimes convulſions. There is another kind which is more ſuperficial, and is either rheumatic or eryſipetalous, in which the fever is more eaſily and ſpeedily cured, by promoting a diaphoreſis; and perſons in years, who are affected with the ſcurvy, gout, rheumatiſm, or violent head-achs, are moſt ſubject to it, eſpecially if they catch cold from a north wind. The former ariſes commonly from the ſtoppage of the menſes, bleeding piles, or other uſual ſanguinary evacuations, and not ſeldom from a virulent gonorrhœa, unſkilfully ſuppreſſed by aſtringents; or when treated by medicines of too ſharp and hot a nature.

This diſeaſe is mortal, if it terminates in an ulcer, or mortification: the latter is immediate death.

The cure muſt be attempted, ſays Hoffman, with bleeding in the foot, if a ſuppreſſion of the menſes or hæmorrhoidal flux be the cauſe. If it proceeds from the ſcurvy, &c. recourſe muſt be had to gentle diaphoretics, diluents, and remedies which obtund the acrimony of the humours, ſuch as decoctions of the root of ſcorzonera, china, ſkirrets, and fennel. Alſo infuſions in the manner of tea of the tops of yarrow, flowers of mallows, winter cherries, and ſeed of daucus, made with milk, and ſweetened with ſyrup of marſh-mallows. To theſe may be added emulſions of the four cold ſeeds. If the patient is coſtive, manna will be proper with antimoniated nitre, to which rhubarb may be joined, as occaſion requires. If the diſeaſe is violent, diaphoretic powders with nitre, in a larger proportion than ordinary, as alſo five grains of ſaffron, and two of camphire, with the emulſions aforeſaid. External antiſpaſmodics, and gentle diſcutients will be proper; for which purpoſe it was Hoffman's me-

thod to apply bladders, filled with a decoction of emollient flowers. If the teneſmus and difficulty of urine ariſe from ſpaſms, there is nothing better than the vapours of a decoction in milk of the flowers of melilot, elder, chamomile and mallows, and the tops of yarrow. This decoction may be put into a cloſe-ſtool, and the patient ſit over it.

INFLAMMATION *of the Brain.* See PHRENSY.

INFLAMMATION *of the Diaphragm.* See the article PARAPHRENITIS.

INFLAMMATION *of the Eyes.* See the article OPHTHALMIA.

INFLAMMATION *of the Fauces.* See the article QUINSEY.

INFLAMMATION *of the Inteſtines*, according to Boerhaave, is an inflammation contracting the inteſtines, and ſtopping up the paſſage through them; attended with a vehement, fixed, burning pain, which is irritated by things taken inwardly. When the inflammation is in the upper part of the inteſtines, the ſtomach will be greatly diſtended with wind. When the pain is exaſperated, it produces convulſions of the diaphragm and abdominal muſcles; vomiting, and painful inflations, with rumblings and ſharp griping pains, which may bring on the iliac paſſion, or twiſting of the guts. Hoffman ſays, that when there is a burning pain in the abdomen, with a preternatural heat of the whole body, as alſo a quick pulſe, loſs of ſtrength, anxiety and inquietude, the ſeat of the diſeaſe may juſtly be ſuſpected to be in the inteſtines. If the pain is above the navel, and below the ſtomach, attended with a fever, nauſea, and reaching, it is a ſign that that part of the colon is affected which lies beneath the ſtomach, and is extended from the right to the left ſide. If the pain lies in the right hypochondrium, under the ſpurious ribs, it ſhews that part of the colon to be inflamed where it joins with the ilium. When the complaint is on the left ſide, under the loins, where the pſoas muſcle is placed, it is a ſign that the colon, and that part of the meſentery joined thereto, is the ſeat of the diſeaſe, eſpecially when it adheres to the peritonæum: but when the pain is in the middle of the abdomen about the navel, it ſhews the ſmall guts are certainly affected; in all which caſes the pain is ſuppoſed to be attended with a fever.

Arbuthnot adviſes, that this diſeaſe be carefully diſtinguiſhed from a colic, proceeding from a cold cauſe; becauſe what is good for the latter is poiſon in the former. It muſt have a ſpeedy remedy, or it will ſoon, according to that writer, end in the iliac paſſion, or a mortification. Beſides copious bleeding, he thinks there is ſcarcely any other method of cure than fomenting and relaxing the bowels with emollient liquids taken warm, both by the mouth and in clyſters, and this every hour: warm fomentations, or young, vigorous, and ſound animals applied to the body are extremely beneficial.

Boerhaave directs, that the patient ſhould only be nouriſhed with broth, in which gently detergent roots have been boiled.

After bleeding and clyſters, if the pain continues violent, Hoffman is of opinion that there will be no manner of danger in giving opiates, by which means the excruciating pain will be alleviated, and the ſpaſms appeaſed, and a breathing ſweat will follow. When this is done, and the fever abated, there will be no occaſion to continue the dilating, relaxing, and moiſtening medicines, but rather the nervous and corroborating; ſuch as the preparations of amber, eſpecially the ſalt and tincture; the former of which may be given in a bolus from ſix to ſixteen grains, and the latter from twenty to eighty drops, in any convenient vehicle.

If the patient ſurvives three days, and the acuteneſs of the pain abates with a chilneſs and ſhivering throughout the body, it is a ſign of a ſuppuration; and within fourteen days the impoſthume will break, and if it falls into the cavity of the abdomen, it will corrupt the whole maſs of fluids, putrify the viſcera, and turn to an aſcites; whence the patient will die of a conſumption. In this caſe, Boerhaave and Arbuthnot recommend whey and chalybeat waters, as likely to prove moſt beneficial. The impoſthume may alſo turn either to a gangrene or ſcirrhus, both which are mortal.

INFLAMMATION *of the Kidneys.* See the article NEPHRITIS.

INFLAMMATION *of the Liver.* When the liver is inflamed, it compreſſes the ſtomach, diaphragm, and the neighbouring viſcera of the abdomen; it ſtops the circulation of the fluids, hinders the generation and excretion of the gall, and all digeſtion; it produces a great many bad ſymptoms, as the jaundice, with all the diſeaſes depending thereon. See HEPATITIS.

A fever, an inflammation, and pungent pain on the region of the liver; and diaphragm, a tenſion of the hypochondria, yellowneſs of the ſkin and eyes, and a ſaffron-coloured urine, are ſigns of an inflammatory diſpoſition of the liver. See JAUNDICE.

This diſeaſe terminates as other inflammations; being cured by reſolution, concoction, and excretion, of the morbid matter; or it terminates in an abſceſs, ſcirrhus, or gangrene. See ABSCESS, &c.

During the firſt ſtate, Arbuthnot tells us, that a warm regimen and ſaffron, which ſome reckon a ſpecific, are improper. On the other hand, that cooling, reſolving liquors, taken inwardly, as whey and ſorrel boiled in it, outward fomentations, and frequent injections of clyſters, bathing and frictions, relax and render the matter fluid. Honey, with a little rheniſh wine and vinegar, the juices and jellies of ſome ripe garden fruits, and thoſe of ſome lacteſcent plants, as endive, dandelion, and lettuce, are reſolvent. Violent purging hurts; gently relaxing the belly relieves, diluents with nitrous ſalts are beneficial; or tamarinds boiled in warm water, or whey. The feveriſh matter is often carried off by urine, and therefore diuretics not highly ſtimulating are proper.

If the inflammation be recent, extremely violent, and without any ſigns or hopes of reſolution, concoction, and excretion, Boerhaave adviſes, that the caſe be treated with the ſame cautions and remedies as is directed in pleuriſies, and other ſimilar inflammatory diſorders; ſuch remedies only excepted, as the ſituation of the part affected cannot admit of, except only, that all antiphlogiſtic fluids, either drank or injected by clyſters, are particularly ſerviceable in the caſe before us.

INFLAMMATION *of the Lungs.* See the article PERIPNEUMONY.

INFLAMMATION *of the Pleura.* See the article PLEURISY.

INFLAMMATION *of the Stomach* is known by a burning, fixed, and pungent pain in the ſtomach, which is exaſperated at the inſtant any thing is taken into it, and is ſucceeded by a moſt painful vomiting and hiccough. There is, beſides, an inward heat, anxiety, and a tenſive pain about the præcordia, an acute continual fever, great thirſt, difficult breathing, inquietude, toſſing of the body, coldneſs of the extreme parts, a hard, contracted, quick, and ſometimes, unequal pulſe. In the medical eſſays, we have an inſtance of this diſeaſe being attended with a hydrophobia. See the article HYDROPHOBIA.

Boerhaave ſays, that this diſeaſe, if not ſuddenly cured, is generally mortal: therefore, that as ſoon as it is diſcovered, plentiful bleeding is neceſſary; that the patient's drink ſhould be very ſoft, antiphlogiſtic, and emollient; and alſo that clyſters of the ſame kind ſhould be adminiſtred.

Arbuthnot adviſes, that the patient ſhould totally abſtain from every thing that has acrimony in it; even the cooling nitrous ſalts, which are beneficial in other inflammations, irritate too much. Vomits, cordials, and ſpirituous liquors, are little better than poiſon: milk generally curdles. Aliments muſt be given frequently, and by a ſpoonful at a time, for any diſtenſion increaſes the inflammation. A thin gruel of barley, oatmeal, whey, with a very little ſugar, or honey, or chicken broths, are proper aliments: whey emulſions, barley-water, and emollient decoctions are proper drinks. If poiſons of the cauſtic kind or metallic medicines ill prepared cauſe the inflammation, oily fat things are proper, as new milk, cream, oil of ſweet almonds, or oil of olives taken often and plentifully, according to Hoffman. If in the cholera morbus an inflammation is apprehended, he adviſes abſorbents and burnt hart's horn, with gelatinous decoctions of calves and neats feet, or hartſhorn-jellies, and

water-gruel. Outwardly he recommends the following liniment as uſeful in all caſes; take oil of ſweet almonds, two ounces; camphire, one dram; make a liniment, with which anoint frequently the precordia, applying a hot linen-cloth over it. The following epithem he recommends as an excellent diſcutient and ſudorific. Take of the vinegar of roſes, two ounces; ſpirit of wine camphorated, two drams; tincture of ſaffron, and tincture of caſtor, of each one dram; nitre, half a dram: let this epithem be applied warm to the region of the ſtomach.

If there happens an impoſthume, honey, and even honey of roſes, taken inwardly, is, according to Arbuthnot, a good cleanſer; and decoctions of comfrey-roots, healing.

INFLAMMATION *of the Womb or Uterus*, appears from extraordinary heat and a fixed pain in the groin, with an acute fever, a pain in the loins and belly, an inflation of the abdomen, a ſtimulus to make water and to go to ſtool, heat, and a difficulty of urine.

Other ſymptoms, according to Aſtruc, are a tumor, pain, heat, tenſion of the hypogaſtric region, redneſs of the os uteri, and great heat of the vagina. If the fore part of the uterus is affected, there is a dyſury; if the back part, a teneſmus; frequent faintings and cardialgia, a burning fever; or, if the inflammation is violent, a lipyria, in which the external parts or extremities are cold, and the internal burn, and the pulſe is imperceptible; a delirium and phrenſy; the breaſts ſwell, in proportion as the inflamed uterus.

Hoffman diſtinguiſhes this diſeaſe into the ſuperficial and more profound. He ſays, that it is eaſily formed in child-bed women, and frequently accompanies the milk-fever, and may be cured in a few days if rightly managed. But that when it is more intenſe, and attended with grievous ſymptoms without remiſſion, it kills on the ſeventh, ninth, or eleventh day; a white miliary fever generally ſupervenes, which is the worſt omen, as it ſhews a mortification of the uterus. See the article MILIARY FEVER.

INFLAMMATORY DISEASES. To theſe may be referred the ſeveral diſeaſes mentioned in the preceding article, either attended with a fever, as leſſer inflammation without a fever; beſides all chronic diſorders ariſing from inflammations, the chief of which are old coughs, conſumptions, and the rheumatiſm, without a fever. See COUGH.

INFLAMMATORY FEVERS are diſtinguiſhed into two ſtages; the firſt, whilſt the pulſe continues hard, in which it is proper to bleed; the ſecond, when the inflammatory ſymptoms ſtill remaining, the pulſe is too low for that evacuation; in this ſtate bliſters are the chief remedy, and which, except in a few ſingular caſes, are not to be uſed ſooner. If the bliſters are large, it is better to apply them gradually, than many at a time. See FEVER and INFLAMMATION.

Point of INFLECTION. When a curve AFK (plate LXXVI. *fig.* 5.) is partly convex, and partly concave, to a right line AB or point B; the point F dividing the convex from the concave part, or the end of the one, and the beginning of the other, is called the point of inflection, when the curve being come to F, continues its courſe towards the ſame parts; and the point of retrogreſſion, when the curve returns back again towards the place of its beginning.

Let us ſuppoſe the curve AFK to have the right line AB as a diameter, and the ordinates PM, EF, &c. parallel to each other. Now if you draw the ordinate FE from the point F, and the tangent FL; alſo another ordinate MP from the point M in the concave part AF of the curve, likewiſe a tangent MT; then it is evident that, in curves having a point of inflection, while the abſciſs AP conſtantly increaſes, the part AT of the diameter, intercepted between the vertex of the diameter A and the point T, where the tangent meets the diameter, does likewiſe increaſe until the point P falls in E, after which it continually decreaſes; therefore AT muſt become a maximum AL, when the point P falls in E the point ſought.

In thoſe curves that have a point of retrogreſſion, the part AT continually increaſes, and the abſciſs AP till the point T coincides with L, and afterwards it continually decreaſes; whence AE muſt be a maximum, when the point T coincides with L. Now call AE, x; EF, y; then will $AL = \frac{y\dot{x}}{\dot{y}} - x$, and the fluxion of this will be $\frac{\dot{y}\dot{y}\dot{x} - y\dot{x}\ddot{y}}{\dot{y}\dot{y}} - \dot{x}$, ſuppoſing $\dot{x}$ invariable; which (being divided by $\dot{x}$ the fluxion of AE) muſt be equal to nothing, or infinite: whence $-\frac{y\ddot{y}}{\dot{y}\dot{y}} = 0$, or infinity; and ſo multiplying by $\dot{y}\dot{y}$, and dividing by $-y$, there comes out $\dot{y} = 0$, or infinite. Now with this laſt expreſſion, and the general equation of a curve, the point of inflection or retrogreſſion F may be found: for the nature of the curve AFK being given, we ſhall have a value of $\dot{y}$ in $\dot{x}$, and putting that value into fluxions, with $\dot{x}$ conſtant, we ſhall obtain a value of $\ddot{y}$ in terms of $\dot{x}\dot{x}$; which being made equal to 0, and afterwards to infinity, by means thereof, in either of theſe ſuppoſitions, we may find AE ſo expreſſed, that its correſpondent ordinate EF ſhall interſect the curve in the point of inflection or retrogreſſion F.

Let the ordinates BM, BF, BM of the curve AFK, all meet in the ſame point B: if any ordinate BM (*fig.* 6.) be drawn, and the tangent MT meeting BT (*fig.* 7.) perpendicular to BM in the point T; and if m (*fig.* 8.) be taken infinitely near M, and the ordinate Bm, tangent mt, the perpendicular Bt to Bm meeting MT in O, be all drawn: then ſuppoſing the ordinate BM, becoming Bm to increaſe, it is plain, in the concave part of the curve, that Bt is greater than BO; and in the convex part the ſame is leſs. So that under the point of inflection or retrogreſſion F, Ot muſt change from negative to poſitive.

This being premiſed, about the center B deſcribe the ſmall arches MR, TH, and there will be formed the ſimilar triangles mRM, MBT, THO, and the little ſimilar ſectors BMR, BTH. Now put BM $= y$; MR $= \dot{x}$; then mR $(\dot{y})$: RM $(\dot{x})$ :: BM (y) : BT $= \frac{y\dot{x}}{\dot{y}}$: MR $(\dot{x})$: TH $= \left(\frac{\dot{x}\dot{x}}{\dot{y}}\right)$ :: TH $\left(\frac{\dot{x}\dot{x}}{\dot{y}}\right)$: HO $= \frac{\dot{x}\dot{x}\dot{x}}{\dot{y}\dot{y}}$. Now take the fluxion of BT $\left(\frac{y\dot{x}}{\dot{y}}\right)$ with $\dot{x}$ invariable, and there will ariſe Bt − BT or H$t = \frac{\dot{x}\dot{y}\dot{y} - y\dot{x}\ddot{y}}{\dot{y}\dot{y}}$; and therefore OH + H$t$ or O$t = \frac{\dot{x}^3 + x\dot{y}^2 - y\dot{x}\ddot{y}}{\dot{y}^2}$. Whence multiplying by $\dot{y}^2$, and dividing by $\dot{x}$, the expreſſion $\dot{x}^2 + \dot{y}^2 - y\ddot{y}$ muſt be nothing or infinite in the point of inflection or retrogreſſion F. Now by the nature of the curve given, we ſhall have values of $\dot{y}$ in $\dot{x}$, and of $\ddot{y}$ in $\dot{x}$, which being ſubſtituted in $\dot{x}^2 + \dot{y}^2 - y\ddot{y}$, there will be produced a quantity, which being made equal firſt to nothing, and afterwards to infinity; by means thereof we may get ſuch a value of BF, that if a circle be deſcribed from B, with the ſame as a radius, it ſhall cut the curve AFK, (*fig.* 5.) in the point of inflection or retrogreſſion F.

Example 1. Let AFK (*fig.* 9.) be a curve, the right line AB being a diameter of it, and let the relation of any abſciſs AE (x) to its correſponding ordinate EF (y) be expreſſed by this equation, $ax^2 = yx^2 + a^2y$. It is required to find ſuch an expreſſion for AE, that the ordinate EF ſhall interſect the curve AFK in the point of inflection F.

The equation of the curve gives $y = \frac{ax^2}{x^2 + a^2}$, and therefore $\dot{y} = \frac{2a^3x\dot{x}}{x^2 + a^2}$, and by taking the fluxion of this quantity with $\dot{x}$ conſtant, there will ariſe $\frac{2a^3\dot{x}^2 \times \overline{x^2 + a^2}^2 - 8ax^2\dot{x}^2 \times \overline{x^2 + a^2}}{\overline{x^2 + a^2}^4}$, which being made equal to nothing, and divided by $2a^3\dot{x}^2 \times \overline{x^2 + a^2}$, will produce $x^2 + a^2 - 4x^2 = 0$. Whence AE $(x) = \frac{a}{\sqrt{3}}$.

If $\frac{1}{3}aa$ be put for its equal xx in the equation of the curve $y = \frac{ax^2}{x^2 + a^2}$, we ſhall have $y = \frac{a}{4}$; ſo that the point of

of inflection F may be determined without ſuppoſing the curve AFK to be deſcribed.

If AC be drawn parallel to the ordinates EF, and made equal to the given right line a, and CG be drawn parallel to AB, the ſame will be an aſymptote to the curve AFK. For if x be made infinite, we may take xx for $xx+aa$, and therefore the value of y will then become equal to a.

Example 2. Let AFK (*fig.* 10.) be the conchoid of Nicomedes, and the point P the pole, the right line BC the aſymptote. It is required to find the point of inflection F; the nature of the curve being ſuch, that a right line PF, drawn from any point F in it to the pole P, meeting the aſymptote BC in D, the part DF thereof is always equal to a given and conſtant quantity a.

Draw PA perpendicular, and EF parallel to BC, alſo DL parallel to BA. Put $BE=x$, $EF=y$, then by the ſimilar triangles DLF, PEF, $DL\ (x) : LF\ (\sqrt{a^2-x^2})$ $::PE\ (b+x) : EF\ (y) = \frac{b+x\times\sqrt{a^2-x^2}}{x}$. The fluxion of this will be $\dot{y} = \frac{x^3\dot{x}+a^2b\dot{x}}{x^2\sqrt{a^2-x^2}}$. Now if you take the fluxion of it again, and make the ſame equal to nothing, there will ariſe $\frac{2a^4b-a^2x^3-3a^2bx^2\times\dot{x}^2}{a^2x^3-x^5\times\sqrt{a^2-x^2}} = 0$, which may be reduced to $x^3+3bx^2-2a^2b=0$; and one of the roots thereof will be the quantity of BE ſought.

If $a=b$, the equation aforegoing will become $x^3+3ax^2-2a^3=0$, which divided by $x+a$, gives $xx+2ax-2aa=0$; and thence x or BE equal to $\sqrt{3a^2}-a$.

Inflection, in grammar, the variation of nouns and verbs, by declenſion and conjugation. See Declension and Conjugation.

Inflex Leaf, among botaniſts, one whoſe point bends inward, towards the ſtem of the plant. See the article Leaf.

Influence, a quality ſuppoſed to flow from the heavenly bodies, either with their light or heat; to which aſtrologers idly aſcribe all ſublunary events.

Influent Fever, the ſame with a nervous one. See the article Fever.

Inforced and Inforcement. See Reinforced and Reinforcement.

In forma Pauperis, in law. See the article Forma.

Information, in law, is nearly the ſame in the crown-office, as what in our other courts is called a declaration. It is ſometimes brought by the king, or his attorney-general, or the clerk of the crown-office; and at other times by a private perſon, who informs or ſues, as well for the king as himſelf, upon the breach of ſome popular ſtatute, in which a penalty is given to the party that will ſue for it. It differs from an indictment, which muſt be found by the oaths of ten men at leaſt; for an information is only the allegation of the perſon that brings it.

Informer, a perſon that informs againſt or proſecutes another, upon any penal ſtatute.

Informis, ſomething irregular in its form, or figure. See the articles Figure and Form.

Hence, *ſtellæ informes*, in aſtronomy, are ſuch of the fixed ſtars as are not reduced into any conſtellation. See the articles Conſtellation and Star.

Infralapsarians, in church-hiſtory, an appellation given to ſuch predeſtinarians, as think the decrees of God, in regard to the ſalvation and damnation of mankind, were formed in conſequence of Adam's fall. See Predestination.

Infrascapularis, in anatomy, one of the depreſſor-muſcles of the arm which has its origin from the whole internal ſurface of the ſcapula, and its termination in the interior part of the humerus. See the article Depressor.

Infraspinatus, in anatomy, one of the abductor-muſcles of the arm, which has its origin in the cavity below the ſpine of the ſcapula. See the article Abductor.

Infundibuliform, in botany, an appellation given to ſuch monopetalous or one-leafed flowers, as reſemble a funnel in ſhape, or which have a narrow tube at one end, and gradually widen towards the limb or mouth. There are two kinds of infundibuliform, or funnel-faſhioned flowers; one of which is like an inverted hollow cone, and the other ſomewhat like a ſaucer, and thence called hypocrateriform. See the article Flower.

Infusion, in pharmacy, a method of obtaining the virtues of plants, roots, &c. by ſteeping them in a hot or cold liquid.

Hot infuſions are made by pouring boiling water, or any other menſtruum, on the drugs whoſe virtues we would extract: thus, in order to obtain the common infuſion of ſena, take the leaves of ſena, an ounce and a half; of cryſtals of tartar, three drams; of the leſſer cardamom-ſeeds huſked, two drams: boil the cryſtals of tartar in a pint of water till they are diſſolved, then pour the water, while boiling hot, upon the ſena and the reſt; and when the liquor is cold, ſtrain it off.

Inganno, in muſic, is when having done every thing proper for ending a cadence, a mark of ſilence is placed inſtead of the final, which the ear naturally expects, and is deceived. See Cadence.

Ingluvies, the crop or craw of granivorous birds, ſerving for the immediate reception of the food, where it is macerated for ſome time, before it is tranſmitted to the true ſtomach.

Ingot, a maſs of gold or ſilver, melted down and caſt in a mould, but not coined or wrought. See Gold and Silver.

Ingraving, or Engraving. See the article Engraving.

Ingredients, in pharmacy, whatever ſimple medicines enter the compoſition of a compound one.

Ingress, in aſtronomy, ſignifies the ſun's entering the firſt ſcruple of one of the four cardinal ſigns, eſpecially aries.

Ingress, Egress, and Regress, in law, words frequently uſed in leaſes of lands, which ſignify a free entry into, a going out of, and returning from ſome part of the premiſes leaſed to another.

Ingrosser, one who buys up great quantities of any commodity, before it comes to market, in order to raiſe the price.

Ingrosser alſo ſignifies a clerk or perſon who copies records, deeds, or other inſtruments of law, on ſkins of parchment.

Inguen, in anatomy, the ſame with what is otherwiſe called groin, or pubes. See Pubes.

Inguinal, in anatomy, &c. any thing belonging to the groin. Hence,

Inguinal Hernia is a hernia in that part, called by ſurgeons bubonocele. See Bubonocele.

Inharmonical Relation, in muſic, is much the ſame with diſcord. See the articles Discord and Relation.

Inheritance, a perpetual right or intereſt in lands, inveſted in a perſon and his heirs.

Inhibition, a writ to forbid a judge's proceeding in a cauſe that lies before him.

Inhumation, in chemiſtry, a method of digeſting ſubſtances by burying the veſſel, in which they are contained, in horſe-dung or earth. See the article Digestion.

Injection, in ſurgery, the forcibly throwing certain liquid medicines into the body by means of a ſyringe, tube, clyſter pipe, or the like.

Many diſorders are very difficultly, if at all curable, unleſs ſome proper liquid be injected into the parts affected; which is performed by drawing the liquor into the ſyringe, and forcing it out again into the diſordered parts. In doing this, one caution is extremely neceſſary, viz. to apply the inſtrument very carefully, and to be mindful that the liquor you inject be not too hot or cold.

Anatomical Injection, the filling the veſſels with ſome coloured ſubſtance, in order to make their figures and ramifications viſible.

For this purpoſe, a fine red injection is prepared thus: pour a pint of oil of turpentine on three ounces of vermilion, ſtir them well together, and then ſtrain all through a fine linen cloth. If a green injection is

wanted, diſtilled verdigriſe may be uſed inſtead of the vermilion.

A coarſe injection may be made of one pound of tallow, five ounces of white wax, three ounces of oil of olives, melted together, and adding two ounces of Venice turpentine; and when this is diſſolved, three ounces of vermilion or verdigriſe, are to be thoroughly mixed with the other ingredients, and the whole ſtrained through a linen cloth.

For the manner of preparing bodies to be injected, ſee the article PREPARATION.

INITIATED, in antiquity, a term chiefly uſed in ſpeaking of perſons who were admitted to a participation of the ſacred myſteries among the heathens. See the article MYSTERY.

INJUNCTION, in law, is a writ or kind of prohibition granted in ſeveral caſes; and for the moſt part grounded on an interlocutory order or decree, made in the court of chancery or exchequer, for ſtaying proceedings either in courts of law, or eccleſiaſtical courts.

INJURY, any wrong done to a man's perſon, reputation, or goods. See the articles ASSAULT, TRESPASS, &c.

INK, *Atramentum*, a black liquor generally made of an infuſion of galls, copperas, and a little gum-arabic. See the articles GALLS, COPPERAS, &c.

Compoſition of common Black INK.—"Take one gallon of ſoft water, and pour it boiling hot on one pound of powdered galls, put into a proper veſſel; ſtop the mouth of the veſſel; and ſet it in the ſun in ſummer, or in winter where it may be warmed by any fire; and let it ſtand two or three days. Add then half a pound of green vitriol powdered; and having ſtirred the mixture well together with a wooden ſpatula, let it ſtand again for two or three days, repeating the ſtirring; when add further to it five ounces of gum-arabic diſſolved in a quart of boiling water; and, laſtly, two ounces of alum; after which the ink ſhould be ſtrained through a coarſe linen cloth for uſe."

The galls ſhould be good, or the ink will fail; as it very frequently does from an error in this point. The marks of their goodneſs is, the appearing of a bluiſh colour, and feeling heavy. Where they are light in weight, and of a whitiſh brown colour, without any blue, they ſhould be rejected; or a greater proportion ſhould be uſed.

In moſt of the recipes for the making of ink, gum-arabic is ordered to be put undiſſolved into the mixture of water, galls, and vitriol; but however common, it is certainly a very injudicious practice; for as the gum-arabic is with ſome difficulty diſſolved in ſimple water, and much more ſo in ſuch as is acidulated by ſalts like the vitriol, and clogged likewiſe with the ſolid part of the galls, it is certainly much better to make a ſolution of it in part of the water of which the ink is to be formed, previouſly to its being commixed with the other ingredients; which would otherwiſe, in ſpite of the moſt frequent ſtirrings, keep it at the bottom of the veſſel; and prevent its being ever wholly freed from them, and diſſolved.

Boiling either the infuſion of the galls, or the mixture after the addition of the vitriol, has likewiſe been frequently ordered, and practiſed: but it is not only needleſs, but injurious to the preparation of the ink; as it can have no effect on the vitriol, beſides conducing to the ſolution of it, which is eaſily effected, in the proportion of water proper to be uſed, without any heat; and with reſpect to the galls, their tinging power reſiding in an eſſential oil that is volatile, and will riſe with leſs heat than that of boiling water, it is neceſſarily leſſened by the evaporation; and conſequently, though more of it may be extracted from the galls, yet leſs will be retained in the fluid, than if infuſion with a gentle heat be uſed, inſtead of decoction.

Improved Compoſition of Black-writing INK.—"Take a gallon of ſoft water; and boil it in a pound of chips of logwood for about half an hour. Take the decoction when off the fire, and pour it from the chips while boiling hot on a pound of the beſt Aleppo galls beaten to a powder, and two ounces of pomegranate peels, being put into a proper veſſel. After having ſtirred them well together with a wooden ſpatula for ſome time, place it in the ſun-ſhine in ſummer, or within the warmth of any fire if in winter, for three or four days, ſtirring the mixture again as often as may be convenient. At the end of that time add half a pound of green vitriol powdered; and let the mixture remain four or five days more, ſtirring it as frequently as may be neceſſary: and then add further four ounces of gum-arabic diſſolved in a quart of boiling water; and after giving the ink ſome time to ſettle, ſtrain it off from the dregs, through a coarſe linen cloth; and keep it well ſtopped for uſe."

If the ink be deſired to ſhine more, the proportion of the pomegranate peel muſt be increaſed; and in the country, where the logwood cannot be ſo eaſily procured, a pound of the ripe privet berries may be ſubſtituted for it.

In order to ſecure this ink from growing mouldy, a quarter of a pint or more of ſpirit of wine may be added: but to prevent its containing any acid, which may injure the ink, a little ſalt of tartar or pearl-aſhes ſhould be added previouſly, and the ſpirit poured off from it; which will render it innocent with regard to the colour of the ink.

Preparation of a Powder for forming good Black INK *extemporaneouſly by the addition of Water.*—"Infuſe a pound of galls powdered, and three ounces of pomegranate peels, in a gallon of ſoft water for a week, in a gentle heat; and then ſtrain off the fluid through a coarſe linen cloth: add then to it eight ounces of vitriol diſſolved in a quart of water, and let them remain for a day or two; preparing in the mean time a decoction of logwood, by boiling a pound of the chips in a gallon of water, till one third be waſted; and then ſtraining the remaining fluid while it is hot. Mix the decoction and the ſolution of galls and vitriol together; and add five ounces of gum-arabic; and then evaporate the mixture over a common fire, to about two quarts; when the remaining fluid muſt be put into a veſſel proper for that purpoſe, and reduced to dryneſs in *balneo mariæ*; that is, by hanging the veſſel in boiling water. The maſs left, after the fluid is wholly exhaled, muſt be well powdered; and when wanted for uſe, may be converted into ink by the addition of water."

It was formerly the practice in compounding the portable inks, to mix the galls in ſubſtance with the other ingredients; and form the compoſition only of them with vitriol and gum-arabic, powdered together; but beſides the clogging and fouling it with the ligneous matter of the galls, there could be no dependance on the ſtanding of ink ſo imperfectly formed.

Preparation of Red-writing INK.—"Take of the raſpings of Brazil-wood a quarter of a pound; and infuſe them two or three days in vinegar, which ſhould be colourleſs, where it can be ſo procured. Boil the infuſion then an hour over a gentle fire; and afterwards filter it, while hot, through paper, laid in an earthen cullender. Put it again over the fire, and diſſolve in it, firſt half an ounce of gum-arabic; and afterwards of alum, and white ſugar, each half an ounce."

Care ſhould be taken that the Brazil-wood be not adulterated with the Braziletto or Campeachy, commonly called peachy-wood; which is moſtly the caſe when it is ground: and though a very detrimental fraud, in all inſtances of the application of Brazil-wood to the forming bright red colours, cannot yet be perceived after the mixture of the raſpings, but by trial in uſing them; it is therefore much the beſt way, when it is wanted for purpoſes like this, to procure the true Brazil-wood in pieces; and to ſcrape it with a knife, or raſp it with a very bright file; but all ruſt of iron muſt be carefully avoided, by which means all poſſibility of ſophiſtication is of courſe prevented.

Red ink may likewiſe be prepared, by the above proceſs, of white wine inſtead of vinegar: but it ſhould be four, or be diſpoſed to be ſo; otherwiſe, a third or fourth of vinegar ſhould be added, in order to its taking the ſtronger tincture from the wood. Small beer has been ſometimes uſed for the ſame purpoſe; but the ink will not be ſo bright: and when it is uſed, vinegar ſhould be added, and the quantity of gum-arabic diminiſhed and the ſugar wholly omitted.

Preparation of Red INK *from Vermilion.*—"Take the glair

glair of four eggs, a tea ſpoonful of white ſugar or ſugar-candy beaten to powder, and as much ſpirit of wine; and beat them together till they be of the conſiſtence of oil: then add ſuch a proportion of vermilion as will produce a red colour, ſufficiently ſtrong; and keep the mixture in a ſmall phial, or well ſtopped ink bottle for uſe. The compoſition ſhould be well ſhaken together before it be uſed."

Inſtead of the glair of eggs, gum-water is frequently uſed: but thin ſize made of iſinglaſs with a little honey, is much better for the purpoſe.

Preparation of Black-printing INK *for engraving on Copper, or other nice Purpoſes.* — "Take any quantity of the beſt nut oil, and put it into an iron pot with a cover well fitted to it; of which pot it muſt fill only two thirds. Place it on a fire, and put on the cover till it makes an ebullition; when it muſt be very well ſtirred to prevent its boiling over. Suffer it then to catch fire, or kindle it by a lighted paper; and when it flames, take it from the fire, and place it in a corner of the chimney; where let it continue to burn half an hour; frequently ſtirring it. Extinguiſh then the flame, by putting the cover on the pot; or if that be not effectual, by putting a wet cloth over it. This produces the weak oil which has the principal part in the compoſition of the ink; but a ſtrong oil muſt alſo be prepared by the ſame means, only inſtead of extinguiſhing the flame at the end of half an hour, it muſt be continued till the oil be rendered very thick and glutinous, which muſt be examined by taking a little out of the pot, and ſuffering it to cool; when, if it be found to be extremely adheſive and ropy, ſo as to be drawn out in long threads, it is ſufficiently burnt; and the flame muſt be put out. This is the ſtrong oil, of which a proportion is to be uſed along with the other in the printing ink. Having prepared theſe oils, take half a pound of the Francfort, or any other good black; and grind it with the addition of only ſo much of the weak oil as is neceſſary to make it work on the ſtone, which will be generally ſomething leſs than half the weight. The whole being incorporated together, and afterwards thoroughly well mixed by a ſecond grinding, having only a ſmall quantity on the ſtone at a time, a quantity of the ſtrong oil muſt be added; which may be as much as is equal to the ſize of a ſmall hen's egg. It will then be fit for uſe; and muſt be put into a proper pot, and covered with paper or leather."

There are ſome who add an onion or cruſt of bread to the oil while boiling, in order to take off the greaſineſs; but the burning will ſufficiently do that office when properly managed.

Inſtead of Francfort, or other black commonly uſed, the following compoſition may be ſubſtituted; and will form a much deeper and more beautiful black than can be obtained by any other method.

"Take of the deepeſt Pruſſian blue five parts, and of the deepeſt coloured lake and brown pink, each one part. Grind them well with oil of turpentine: and afterwards with the ſtrong and weak oils in the manner and proportion before directed."

The colours need not be bright for this purpoſe; but they ſhould be the deepeſt of the kind, and perfectly tranſparent in oil, as the whole effect depends on that quality.

Secret or Sympathetic INK. — A great variety of methods have been invented for making ſecret letters; but the moſt common are to write with a colourleſs fluid, which may be made to aſſume the quality of ink, either by embrocating or moiſtening the paper containing the writing with ſome other fluid; or by putting it into a gentle heat; or by immerſing it in water: but many other expedients may be found for forming inviſible letters, which may be occaſionally rendered legible, by applying the proper means.

For preparing ink which may be made to appear occaſionally, the following methods may be purſued.

"Take an ounce of galls powdered; and infuſe them three or four days in half a pint of water. Pour off the clear fluid; and diſſolve in it a dram of gum-arabic: write with this fluid; and when it is deſired to render the writing viſible, rub the paper over with a ſolution of green vitriol or copperas, formed by diſſolving half an ounce of the vitriol in half a pint of water."

Or otherwiſe, "Take two ounces of quick-lime, and one ounce of orpiment; and add to them a pint of water. Let them ſtand in a gentle heat, often ſhaking the veſſel, for ſome hours, or longer if it be convenient; and then pour off the fluid. Make, in the mean time, a ſolution of ſugar of lead, by diſſolving three drams of it in two ounces of water; and with this ſolution write on paper what is required. When it is deſired to render this writing viſible, embrocate or rub over the paper with the fluid taken off from the lime and orpiment, and the letters will immediately appear of a ſtrong blackiſh colour."

In order to make it more eaſy to write with the colourleſs fluids, they may be mixed with burnt corks, ivory black, or charcoal ground to a fine powder; which will render the writing as viſible, as if ink had been uſed; but the paper may be again made to appear blank, by rubbing off the black powder; which may be eaſily done by a ſoft bruſh or linen rag; where, nevertheleſs, any black powder is mixed with the fluid, the gum-arabic, as directed in the firſt recipe, muſt be omitted; otherwiſe the powder will be ſo cemented to the paper, as not to be eaſily taken off from it, without injuring the inviſible writing under it.

Inviſible letters, which may occaſionally be rendered apparent, by holding the paper on which they are written to the fire, may be made by writing with the juice of lemons, or of onions; or with ſal ammoniacum finely powdered and tempered with water, or by the fluid which may be preſſed from the mixture of onion, urine, and ſalt, ground together till they become of an unctuous conſiſtence.

Letters may alſo be formed, which are inviſible till the paper on which they are written be immerſed in water. The eaſieſt method of doing which is, by writing with a ſolution of roach alum; and when it is deſired to have the letters appear, placing the paper in an horizontal ſituation, in a baſon full of water; where, after it has remained ſome time, the writing will ſhew itſelf in a white character very diſtinctly. There are other methods of doing the ſame; but as they are more complex and troubleſome than this, it is needleſs to inſert them.

There is a very neat and eaſy method of uſing a blank writing, that may be made viſible occaſionally; which is, the applying the manner of gilding with the gold armoniac, as it was formerly called, to this purpoſe. It muſt be done by diſſolving gum-armoniacum in water, to which ſome juice of garlic, and a little gum-arabic ſhould be added; and then writing with the mixture: which writing may be rendered viſible at any time by breathing on the paper, and then laying a leaf over the part written upon, which being compreſſed to the paper, and afterwards gently rubbed with a camel's hair-bruſh, or a little cotton, will leave the writing perfectly gilt.

Indian INK is a black pigment brought hither from China, which on being rubbed with water, diſſolves, and forms a ſubſtance reſembling ink; but of a conſiſtence extremely well adapted to the working with a pencil: on which account it is not only much uſed as a black colour in miniature painting, but is the black now generally made uſe of for all ſmaller drawings in chiaro obſcuro, or where the effect is to be produced from light and ſhade only.

The preparation of Indian ink, as well as of the other compoſitions uſed by the Chineſe as paints, is not hitherto revealed on any good authority: but it appears clearly from experiments to be the coal of fiſh-bones, or ſome other vegetable ſubſtance, mixed with iſinglaſs ſize, or other ſize; and, moſt probably, honey or ſugar-candy, to prevent its cracking. A ſubſtance therefore, much of the ſame nature, and applicable to the ſame purpoſes, may be formed in the following manner:

"Take of iſinglaſs ſix ounces, reduce it to a ſize, by diſſolving it over the fire in double its weight of water. Take then of Spaniſh liquorice one ounce; and diſſolve it alſo in double its weight of water; and grind up with it an ounce of ivory black: add this mixture to the ſize while hot; and ſtir the whole together till all the ingredients

dients be thoroughly incorporated: then evaporate away the water in balneo mariæ, and caſt the remaining compoſition into leaden moulds greaſed; or make it up in any other mould."

The colour of this compoſition will be equally good with that of the Indian ink: the iſinglaſs ſize, mixed with the colours, works with the pencil equally well with the Indian ink: and the Spaniſh liquorice will both render it eaſily diſſolvible on the rubbing with water, to which the iſinglaſs alone is ſomewhat reluctant; and alſo prevent its cracking and peeling off from the ground on which it is laid.

INLAYING, the art of marquetry. See MARQUETRY.

INNATE IDEAS, thoſe ſuppoſed to be ſtamped on the mind, from the firſt moment of its exiſtence, and which it conſtantly brings into the world with it: a doctrine which Mr. Locke has abundantly refuted. See the article IDEA.

INNOCENTS DAY, a feſtival of the Chriſtian church, obſerved on December twenty-eight, in memory of the maſſacre of the innocent children by the command of Herod, king of Judea; who being alarmed at hearing that an infant was born king of the Jews, and imagining that his own kingdom was in danger, ſent orders to have all the children ſlain that were in Bethlehem, and the adjacent country.

The Greek church in their calendar, and the Abyſſinians of Ethiopia in their offices, commemorate fourteen thouſand infants on this occaſion.

INNOMINATA OSSA, in anatomy, three bones, which compoſe the extreme part of the trunk of a human body. Theſe, though ſingle in adults, are in infants three perfectly diſtinct bones, each of which has its peculiar name; the upper one is called the ileum; the anterior one, the os pubis, or os pectinis; and the poſterior one, the os pubis, or os iſchium. Theſe are joined by the intervention of a cartilage, as it were in the middle of that ſingular cavity called the acetabulum, and continue viſibly diſtinct to the age of puberty; after which they coaleſce, and form one entire bone ſo perfectly, that there is not the leaſt veſtige remaining that they ever were ſeparate.

The innominata oſſa are joined on each ſide, in the hinder part, to the os ſacrum, by ligaments and cartilages, and form a very firm and ſtrong, though ſomewhat moveable articulation with it; and with this bone they alſo form the cavity called the pelvis; they alſo cohere with the os ſacrum on each ſide, by means of two peculiar and very robuſt ligaments, each being a finger's breadth broad, and two or three fingers breadth long.

The uſe of theſe bones are to ſupport and ſuſtain the ſpina dorſi, and indeed all the parts above themſelves; to make a firm and proper juncture of the other parts of the body with the thighs; to ſerve for the place of origin to ſeveral muſcles; to form the cavity of the pelvis, and to defend its contents from external injuries.

INNUENDO, a word that was frequently uſed in declarations of ſlander, and law pleadings, when theſe were in Latin, in order to aſcertain a perſon or thing beforementioned; but now, inſtead of the word innuendo, we ſay, meaning ſo and ſo.

INOCULATION, in medicine, the art of tranſplanting a diſtemper from one ſubject to another, by inciſion, particularly uſed for engrafting the ſmall-pox. See the article Pox.

The deſign of this operation is to communicate by art a milder ſpecies of the ſmall-pox to the infant or adult patient, than that received by the natural infection; and this by engrafting ſome of the variolous matter, in order to which a ſmall inciſion is to be firſt made, with a ſcalpel or lancet, through the ſkin of the arm; and having inſerted a ſmall particle of the purulent matter, taken from a mild kind of the pock, the little wound is then to be dreſſed with ſome dry lint, and covered with a plaſter. After the operation, the patient muſt conſtantly keep his chamber, the air of which ſhould be moderately warm, and his diet regulated by ſome prudent phyſician, by which means this diſorder will ſhew itſelf in ſeven or eight days, without any malignant ſymptoms and if aſſiſted by a proper regimen, and a moderate warmth, it uſually runs gently through its ſeveral ſtages. When the patient has once had the diſorder this way, though ever ſo mild, it is certain, from experience, that they never have it again; and therefore the opinion of thoſe ſeems to be well grounded, who think that the propagation of the ſmall-pox by inoculation might be of general uſe and benefit to mankind in preſerving the lives of ſome, and the moſt important members of others, as the face, eyes, hearing, viſcera, &c.

Hiſtory informs us, that the diſorder was this way propagated many hundred years ago, among the Greeks, Turks, and Chineſe; whereas it is but of late years that the European nations have come into it, among which the Engliſh ſeem to have approved and followed it moſt. The experiment ſucceeded ſo well in the hands of the Britiſh phyſicians, that king George I. countenanced the ſame in all his dominions, and from thence the practice prevailed with ſucceſs in Germany, particularly in the dominions of Hanover.

It muſt, however, be confeſſed, that there were many, both among the French and Engliſh, who endeavoured to ſuppreſs and vilify the practice in their writings; but it is thought by Heiſter, that all their objections have been ſufficiently anſwered and obviated by Dr. Jurin and other able phyſicians.

Heiſter declares himſelf of opinion, that ſo far from thinking the practice fatal or miſchievous, he rather firmly believes it might, under a proper management, be of the greateſt uſe and benefit to the lives and healths of mankind; for, as he judges, the ſmall pox ariſe from a peſtilential virus or matter lodged in the blood, from the very firſt day of the birth, which breaks out almoſt in every perſon, ſooner or later, and the more early uſually the better, as it is ſeldom we obſerve the pox favourable in thoſe more advanced in years; ſo that the matter ſeems to multiply itſelf in the blood, and augment with the patient's age. If, therefore, the diſorder be procured of a mild kind by this operation, and the blood cleared of its latent virus, while ſmall in quantity, and the infant young, he doubts not but many might by this means be not only preſerved from death, but even conducted ſafely through the ſeveral ſtages of the diſeaſe, without the inſults of its moſt malignant ſymptoms. We are convinced from experience, as well as reaſon, that the diſorder which breaks out from a natural infection, is generally more ſevere and fatal than that produced by art; and no wonder it ſhould be ſo, ſince in the laſt, the phyſician has the opportunity of chooſing the moſt favourable ſeaſon, and of preparing his patient before-hand, by a proper regimen, diet, and medicines.

In the Phil. Tranſ. vol. xlvii. we have a new method of inoculation, diſcovered by Mr. Brooke, and communicated by him, in a letter read before the Royal Society, May 14, 1752, to Dr. Parſons, ſecretary to the ſociety for foreign correſpondence, ſhewing by experiments, that the pock may be engrafted without making any inciſion, only by the application of a little lint impregnated with variolous matter, and confining it with an adheſive plaſter. Mr. Brooke tried the experiment upon ſeveral patients, and always with ſucceſs; the abſorbent veſſels, he believes, in young ſubjects eſpecially, will always take in a ſufficient quantity of the matter to contaminate the whole maſs of the circulating fluids; and though the denſity of the pores, or ſcaly inſpiſſations of the materia perſpirabilis, in adults, may in ſome meaſure prevent the diſorder from being communicated by contact; yet friction will eaſily remove that obſtacle; for by this means the cuticle is made as thin as is required, and the warmth induced by friction will dilate the mouths of the abſorbent veſſels, and draw a moderate flux of juices to that part, ſo that they may take in a ſufficient quantity of variolous matter to bring on the diſorder.

INOCULATION, or BUDDING, in gardening, is commonly practiſed upon all ſorts of ſtone-fruit, as nectarines, peaches, apricots, plums, cherries, as alſo upon oranges and jaſmines; and, indeed, this is preferable to any ſort of grafting for moſt ſorts of fruit. The method of performing it is as follows: you muſt be provided with a ſharp penkniſe with a flat haft, which is to raiſe the bark of

of the ſtock, to admit the bud; and ſome ſound baſs mat, which ſhould be ſoaked in water, to increaſe its ſtrength, and render it more pliable; then having taken off the cuttings from the trees you would propagate, you muſt chooſe a ſmooth part of the ſtock, about five or ſix inches above the ſurface of the ground, if deſigned for dwarfs; but if for ſtandards, they ſhould be budded ſix feet above ground. Then with your knife make an horizontal cut acroſs the rind of the ſtock, and from the middle of that cut make a ſlit downwards, about two inches in length, ſo that it may be in the form of a T; but you muſt be careful not to cut too deep, leſt you wound the ſtock; then having cut off the leaf from the bud, leaving the foot ſtalk remaining, you ſhould make a croſs cut, about half an inch below the eye, and with your knife ſlit off the bud, with part of the wood to it: this done, you muſt with your knife pull off that part of the wood which was taken with the bud, obſerving whether the eye of the bud be left to it or not; for all thoſe buds which loſe their eyes in ſtripping, are good for nothing: then having gently raiſed the bark of the ſtock with the flat haſt of your penknife clear to the wood, thruſt the bud therein, obſerving to place it ſmooth between the rind and wood of the ſtock, cutting off any part of the rind belonging to the bud, that may be too long for the ſlit made in the ſtock; and ſo having exactly fitted the bud to the ſtock, tie them cloſely round with baſs mat, beginning at the under part of the ſlit, and ſo proceeding to the top, taking care not to bind round the eye of the bud, which ſhould be left open.

When your buds have been inoculated three weeks or a month, thoſe which are freſh and plump, you may be ſure are joined; and at this time you ſhould looſen the bandage, which if it be not done in time, will injure if not deſtroy the bud. The March following cut off the ſtock ſloping, about three inches above the bud, and to what is left faſten the ſhoot which proceeds from the bud: but this muſt continue no longer than one year; after which the ſtock muſt be cut off cloſe above the bud. The time for inoculating is from the middle of June to the middle of Auguſt; but the moſt general rule is, when you obſerve the buds formed at the extremity of the ſame year's ſhoot, which is a ſign of their having finiſhed their ſpring growth. The firſt ſort commonly inoculated is the apricot, and the laſt the orange-tree, which ſhould never be done till the latter end of Auguſt: and in doing this work, you ſhould always make choice of cloudy weather; for if it be done in the middle of the day, when the weather is hot, the ſhoots will perſpire ſo faſt, as to leave the buds deſtitute of moiſture.

INORDINATE PROPORTION is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus, ſuppoſe the numbers in one rank to be 2, 3, 9; and thoſe of the other rank 8, 24, 36; which are compared in a different order, viz. 2 : 3 :: 24 : 36; and 3 : 9 :: 8 : 24. Then rejecting the mean terms of each rank, you conclude 2 : 9 :: 8 : 36.

INOSCULATION, in anatomy, the ſame with anaſtomaſis. See ANASTOMASIS.

INQUEST, in law, ſignifies an enquiry made by a jury, in a civil or criminal cauſe, by examining witneſſes. See the article JURY.

INQUIRENDO, in law, an authority given to one or more perſons, to enquire into ſomething for the advantage of the king.

INQUISITION, in law, a manner of proceeding by way of ſearch or examination uſed on the king's behalf, in caſes of out-lawry, treaſon, felony, ſelf-murder, &c. to diſcover lands, goods, and the like, forfeited to the crown.

INQUISITION, in the church of Rome, a tribunal in ſeveral Roman-catholic countries, erected by the popes for the examination and puniſhment of heretics.

This court was founded in the twelfth century by father Dominic and his followers, who were ſent by pope Innocent III. with orders to excite the Catholic princes and people to extirpate heretics, to ſearch into their number and quality, and to tranſmit a faithful account thereof to Rome. Hence they were called inquiſitors; and this gave birth to the formidable tribunal of the inquiſition, which was received in all Italy, and the dominions of Spain, except the kingdom of Naples and the Low-Countries.

This diabolical tribunal takes cognizance of hereſy, judaiſm, mahometaniſm, ſodomy, and polygamy; and the people ſtand in ſo much fear of it, that parents deliver up their children, huſbands their wives, and maſters their ſervants, to its officers, without daring in the leaſt to murmur. The priſoners are kept for a long time, till they themſelves turn their own accuſers, and declare the cauſe of their impriſonment; for they are neither told their crime, nor confronted with witneſſes. As ſoon as they are impriſoned their friends go into mourning, and ſpeak of them as dead, not daring to ſollicit their pardon, leſt they ſhould be brought in as accomplices. When there is no ſhadow of proof againſt the pretended criminal, he is diſcharged, after ſuffering the moſt cruel tortures, a tedious and dreadful impriſonment, and the loſs of the greateſt part of his effects. The ſentence againſt the priſoners is pronounced publicly, and with extraordinary ſolemnity. In Portugal they erect a theatre capable of holding three thouſand perſons, in which they place a rich altar, and raiſe ſeats on each ſide in the form of an amphitheatre. There the priſoners are placed, and over-againſt them is a high chair, whither they are called, one by one, to hear their doom, from one of the inquiſitors.

Theſe unhappy people know what they are to ſuffer, by the cloaths they wear that day. Thoſe who appear in their own cloaths, are diſcharged upon payment of a fine: thoſe who have a ſanto benito, or ſtrait yellow coat without ſleeves, charged with St. Andrew's croſs, have their lives, but forfeit all their effects: thoſe who have the reſemblance of flames, made of red ſerge, ſewed upon their ſanto benito, without any croſs, are pardoned, but threatened to be burnt if ever they relapſe: but thoſe who, beſides theſe flames, have on their ſanto benito, their own picture, ſurrounded with figures of devils, are condemned to expire in the flames. The inquiſitors, who are eccleſiaſtics, do not pronouce the ſentence of death; but form and read an act, in which they ſay, that the criminal being convicted of ſuch a crime, by his own confeſſion, is with much reluctance delivered to the ſecular power to be puniſhed according to his demerits: and this writing they give to the ſeven judges, who attend at the right ſide of the altar, who immediately paſs ſentence. For the concluſion of this horrid ſcene, ſee the article ACT *of Faith*.

INQUISITORS, in law, perſons who have power by their office to make inquiry in certain caſes; as ſheriffs, and coroners on view of the body, &c.

INROLLMENT, in law, is regiſtering any lawful act, as a ſtatute or recognizance acknowledged, a deed of bargain and ſale, &c. in the rolls of chancery, king's bench, common pleas, or exchequer, at the huſtings of Guildhall, London, or at the quarter-ſeſſions.

INSCONSED, in the military art, part of an army that have fortified themſelves with a ſconce or ſmall fort, in order to defend ſome paſs, &c.

INSCRIBED, in geometry. A figure is ſaid to be inſcribed in another, when all its angles touch the ſides or planes of the other figure. See HEXAGON, PENTAGON, &c.

INSCRIPTION, a title or writing carved, engraved, or affixed to any thing, to give a more diſtinct knowledge of it, or to tranſmit ſome important truth to poſterity.

INSECTS, *Inſecta*, in natural hiſtory, a ſmaller kind of animals, that commonly are exſanguinous.

The word is Latin, and derived from *in*, and *ſeco*, to cut, becauſe in ſome inſects, as ants, the body ſeems divided into two; or becauſe the bodies of ſeveral of them, as worms, &c. conſiſt of divers rings, which are a ſort of inciſure.

Mr. Ray, in his *Methodus Inſectorum*, divides inſects into ſuch as do not change their form; and into ſuch as really do.

Inſects which do not change their form are either without feet, or with feet: and of theſe there are ſome kinds that caſt their ſkins, and others that do not.

Inſects without feet are either terreſtrial or aquatic. The terreſtrial are ſuch as are produced on the earth, as

the lumbrici terreſtres, which are either of the larger ſort, and called dew-worms, or of a ſmaller ſize: and of theſe there are ſome red, and others green with yellow tails; which laſt are commonly called gilt-tails: or, ſecondly, ſuch as are found in the bowels of animals, of which ſome are found in the inteſtines of men, as the lumbrici teretes. 2. The lumbrici lati, which are alſo called tæniæ. 3. Cucurbitini, which ſome take to be only fragments of the tæniæ. 4. Aſcarides, which are chiefly found in the rectum. Others are found in the inteſtines of beaſts, which are of two ſorts; the oblongi and pellucidi, of the thickneſs of a horſe-hair, and therefore called vermiculi ſetiformes: and the breves and craſſiores which are found in horſes, and called the botts.

To the genus of terreſtrial inſects many refer ſnails, whether with or without ſhells.

Aquatic inſects without feet, that do not change their form, are either, 1. Of the larger ſort, that, by fixing their heads to the ground, draw up their tails towards them, &c. Of theſe ſome are round and ſmooth, and are of three ſorts, as the medicinal hirundines or leeches, the common black horſe-leeches, and the aſh-coloured ſea-leeches; but there is alſo a ſmaller and flatter kind that ſtick to the ſtones in the bottom of ſmall brooks. Or of the leſſer ſort that move differently from the former; theſe are alſo either round or flat; of the round ſort there is one that is black with two ſmall horns on its head, found ſticking to wet ſtones on the tops of the hills; and another that is red, about a finger's length, with a forceps at the tail, found at the bottom of fiſh-ponds and ſtagnant waters. The flat ſort are very ſmall and thin, and called flukes, being ſometimes found in waters, and ſometimes in the branches of the porus biliarius in ſheep.

Inſects that do not change form, and have feet, are, 1. Thoſe with ſix feet. 2. Thoſe with eight feet. 3. Thoſe with fourteen feet; and, 4. Thoſe with many feet.

Thoſe of ſix feet are terreſtrial or aquatic: the terreſtrial are either of a larger kind, as 1. The yellowiſh inſect found in decaying oaks. 2. The black one on the ground, called vermivorous by Mouffet. 3. The black one living under ground, with a forceps at the tail. 4. A white ſort with ſquare black ſpots on its back. 5. The farinarium, that is bred in meal, of a whitiſh colour. Or, ſecondly, a ſmaller ſort, ſome of which are found about the bodies of animals, as 1. The cimex, bug, or wall-louſe, of a ſtinking ſmell. 2. Ricinus, the tick. 3. Pediculus, the common louſe. 4. Pediculus, the ferus ſeu inguinalis, the crab-louſe. 5. Pulex, the flea, of which there are various kinds. Others are not found on the bodies of animals; as, 1. One that reſembles a common louſe in bigneſs and figure, but is very nimble, and found in books and rotten paper. 2. Another with a very long body and a forcipital tail. 3. The black inſect found often in the flowers of the chelidonium. 4. A ſubterraneous ſort, a little whitiſh. 5. One that ſkips like a graſs-hopper, but much leſs.

The aquatic are, 1. The pediculus marinus grandis, which adheres to fiſhes. 2. The ſquilla fluviatilis, with a pyramidal tail, and two hairs or briſtles at the end.

Inſects that do not change form with eight feet, either have a tail, as the ſcorpion; or are without, as, 1. The ſpider; of which ſome ſpin no web, have but two eyes, and very long legs, as the opilio or ſhepherd: others ſpin a web; and of theſe they reckon three ſorts, 1. The aranea colceſtrenſis abdomine tumido, ſubrotundo, et elato. 2. The ſpider, with the thorax or middle part of the body as big as the abdomen. 3. The ſpider, with the long abdomen, found among reeds, ruſhes, graſs, &c. Secondly, the ticks with eight feet, of which ſome are more flat, as the rambling ticks that run over the bodies of animals, but do not faſten; and ſome more round and thick, which adhere to the ſkin. Thirdly, the ſyrones or mites. Inſects that do not change form, and with fourteen feet, are the aſelli; of which there are three ſorts, as, 1. The ſea aſellus, the longeſt and largeſt of all, living among the rocks, 2. Aſellus lividus, which rolls itſelf up into a ball. The common wood-lice, ſows, or cheſs-bugs. 3. Aſellus aſininus with a forked tail, not rolling itſelf up. To theſe ſpecies may likewiſe be added, 1. The aſellus marinus figuræ brevioris, rolling itſelf up. 2. Aſellus aquarum dulcium, with long legs and two briſtles on its tail. 3. Pulex aquaticus, both in freſh and ſalt water. 4. Pediculus aquaticus, which faſtens upon fiſh.

Inſects that do not change form, and with twenty-four feet, have the eight fore-feet leſſer, and the ſixteen hinder ones larger; there are two kinds of them, both with long bodies; the one larger, and of a dark colour, among the rocks by the ſea-ſide; the other of a ſilver colour, found in houſes.

There is a kind with thirty feet, of an oblong ſhape, cheſnut colour, and full flattiſh body, uſually lying under logs and trunks of trees; it is very agile.

Inſects that do not change form, and have many feet, are ſome on land, and either roundiſh in body, with all their legs riſing out of the middle of the belly nearly, as the julus; or more flat, with their legs not riſing as before from a point in the middle of their body, but growing along on the ſides, as the ſcolopendra. Others are aquatic, of which Mr. Ray makes three differences; 1. The Corniſh lugs, uſed as a bait for catching fiſh, with thirty-eight legs, and a ſmooth roundiſh body. 2. The ſcolopendra marina corpore plano. 3. The animalculum bicorpor, or rather bicaudatum, lying in the cleſts of ſtones under ſalt water.

Inſects which undergo a change, are improperly ſo denominated, as Swammerdam ſhews that there is only an explication of the parts of the animal, latent both in miniature, like the plant in the ſeed, and an increaſe of all the parts by proper degrees. The firſt ſpecies of tranſmutation is inſtantaneous. The inſects of this order do not loſe their motion at the time they ſhift their pellicles, at leaſt not to appearance. This is when the vermiculus, leaving the former ſhape of the nympha, with which it appeared in the egg, and ſubſiſted without food, now beginning to feed, has its parts viſibly ſtretched out, and takes the form of a new nympha, which is not without motion, and from thence becomes a flying inſect. Of this ſort are, 1. The libellæ or perlæ, which are produced from an inſect of ſix feet, and which Mouffet takes for the pulex marinus, or locuſta aquatica. Out of the cruſtaceous huſk of this inſect, the libella breaks by a fiſſure which begins between the eyes, and is continued to the roots of the wings, and is there joined to the lateral fiſſures. 2. The cimices ſilveſtres, whoſe characteriſtics, according to Willughby, are, 1. A long proboſcis, not ſpiral but ſtraight. 2. Their upper wings to the middle are thick and like leather, and thence to the extremities thin and membranous. 3. The figure of St. Andrew's croſs on the back. 4. The locuſta which Willughby refers to thoſe inſects that are not transformed. 5. The grylli campeſtres. 6. Grylli domeſtici or crickets. 7. Gryllo-talpa, the mole-cricket. 8. Cicada or graſshopper. 9. Blatta, according to Swammerdam. 10. Tipulæ aquaticæ, which run ſwiftly on the ſurface of the water, and have a ſting in their mouths, like the ticks or cimices. 11. Scorpius aquaticus, with a ſting in its mouth. 12. Muſcæ aquaticæ, which Aldrovandus calls apes amphibiæ. 13. Hemerobius or ephemera, or diaria of Swammerdam. 14. The forficula or auricularia.

The ſecond ſpecies of tranſmutation includes ſuch inſects as undergo a double metamorphoſis. 1. Into a chryſalis, or ſomething analogous thereto. 2. A flying inſect.

Theſe inſects, a while before they change, lie quite ſtill, and, with regard to their wings, are vaginipennes as the ſcarabæi or beetles. Secondly, thoſe whoſe wings are open, and theſe are either farinaceous, as the papiliones &c. or membranous, as the apes, muſcæ, &c. and they are either with two wings or with four. The ſcarabæ may be divided, 1. In reſpect of their horns, into the naſicornis, bucerota, and cervus volans or taurus. 2. In reſpect of their antennæ, which are of divers kinds, of which the moſt conſiderable are the capricorni. 3. With regard to their motion, as the ſaltatrices. 4. With reſpect to their colour, as the cantharides.

To the beetle kind may likewiſe be referred the cicindela or glow-worm; the ſtaphylinus; the proſcarabæus or oil-beetle, as, upon ſqueezing, a kind of oil is emitted from its joints: the anelytra with mealy wings, called papiliones, butterflies; and theſe are either diurnal or nocturnal: the characteriſtic of the diurnal is, that they always

always ſettle with their wings erect, are produced from an angular aurelia, and have their antennæ ſtudded; of theſe there are about fifty ſorts obſerved in England. The nocturnal butterflies or phalenæ are very numerous, and cannot be clearly methodized: but they may be divided into, 1. Geometrigenæ, which come from an eruca called geometra, from the manner of its walking, which is anſatinous, by curling up its back like the handle of a cup, with eight or ten feet. 2. Such as come from erucæ with fourteen feet: of this kind, which is very numerous, there hath been diſtinguiſhed the phalæna faſciata, whoſe wings are in areas of divers colours; phalæna lineata, whoſe wings are marked with tranſverſe lines; phalæna punctata, whoſe wings are marked with points; and, except theſe, all the others are diſtinguiſhed into greater, leſſer, and of a middling ſize. One of the larger kinds may be diſtinguiſhed likewiſe by their inner wings running out beyond the upper, when they reſt; and another by the appearance of eyes upon the wings; and a third by their long nails and narrow ſharp wings, which ſome call phalænæ prædatrices, or accipitrinæ.

The anelytra, with membranous wings, are bees, flies, waſps, bombylii, crabrones, &c. and to this kind Swammerdam refers the culex vulgaris or gnat, as alſo the formica or ant.

Hitherto alſo muſt be referred ſuch water inſects as are covered with a theca or caſe, according to Willughby. Theſe are, firſt, an immoveable caſe fixed to the ſtones; and this is either of a round figure, or one more compreſſed. Secondly, a moveable, portable caſe; and theſe are commonly called phryganæa; and their theca is, 1. Straight, and that either compoſed of ſtraws and little feſtucæ, lying parallel to one another; of which there are two kinds; a larger, where the feſtucæ are two inches long; and a leſſer, which are very common, and called ſtraw-worms. Or elſe the feſtucæ lie tranſverſely, and are ſhorter, having ſometimes pieces of ſhells or ſtones intermixed with them; others, whoſe caſes are ſtraight, have no feſtucæ, but always, either ſand or gravel; and of theſe ſome have the theca round, and called cod-baits; others are flat. 2. Crooked or horned, which run tapering; of theſe Mr. Ray reckons four kinds; a greater and leſs black ſort, and a greater and leſs aſh-coloured one. Theſe all produce flies with large wings, like butterflies.

The third ſpecies of tranſmutation is a ſimple change from a vermiculus to a flying inſect, but with a ſenſible ſtop between one form and the other of this kind are our fleſh flies, and all the nymphæ vermiformes, the veſpæ, ichneumones, &c.

As to the generation of inſects, the world is now generally convinced that they are not bred of corruption, but *ex ovo*, though the contrary was believed by the ancients.

Malpighi, Swammerdam, and Redi, have abundantly confuted the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly; and have ſhewn, that all the members of the butterfly were incloſed under the nympha or ſkin of the caterpillar, as the parts of a plant are in the ſeed.

Inſects take particular care to depoſit their eggs or ſemen in ſuch places where they may have a ſufficient incubation, and where the young, when hatched, may have proper food till they can ſhift for themſelves. Thoſe whoſe food is in the water, lay their eggs there: thoſe to whom fleſh is a proper food, in fleſh; and thoſe to whom the fruits or leaves of vegetables are food, are accordingly depoſited there, but conſtantly the ſame kind in the ſame tree. As for others that require a greater degree of warmth, they are provided by the parent with ſome place in or about the body of other animals, as the feathers of birds, hair of beaſts, ſcales of fiſh, in the noſe, in the fleſh, nay ſome in the bowels of man, and other creatures. And as for others, they make them neſts, by digging into the earth, wood, &c. carrying in and ſealing up proviſions that ſerve for the production of their young, and for their food, when produced.

There is obſerved in flies, butterflies, &c. a kind of glue, by which the female faſtens her eggs to the bearing buds of trees, &c. ſo as not to be hurt by rain or froſt.

Mr. Andry, in his Treatiſe *de la generation des vers dans le corps de l'homme*, takes notice that the ancients were miſtaken in denying that inſects breathed, on account of their wanting lungs; for modern obſervations convince us, that inſects have a greater number of lungs than other animals; they alſo thought that they had no blood, as many of them had no red liquor like ours; but it is not the colour, but the uſe of the liquor, that is to be regarded. They alſo believed that they had no hearts; whereas our microſcopes now diſcover that, when inſects have ſeveral lungs, they have alſo ſeveral hearts; and this in particular is obſervable in ſilk-worms, who have a continued chain of hearts from the head almoſt to the extremity of the tail; and, as is apparent from ſeveral inſects, who give ſigns of life, long after they are divided into ſeveral parts.

Inſects want no parts that are either neceſſary or convenient for their uſe, or to render them complete in their kind. Some affirm that earth worms, and thoſe round-tailed worms, which are found in the inteſtines of men, horſes, &c. as alſo ſnails and horſe-leeches, are hermaphrodites; but that ſuch worms as become flies, and that ſilk-worms, are not ſo, being of no ſex, but neſts full of real animals, which in time come out with wings.

INSIDIANT DISEASES, thoſe which ſhew no evident ſymptom, but lie concealed in the body, ready to break forth on the leaſt provocation, as it were by ſurpriſe.

INSITION, in gardening, the ſame with grafting. See GRAFTING.

INSOLATION, in chemiſtry, the ſuffering matters to ſtand and digeſt in the heat of the ſun, inſtead of that of a furnace. See FIRE and HEAT.

INSOLVENT, a term applied to perſons unable to pay their debts. See DEBT and DEBTOR.

INSPIRATION, *Inſpiratio*, the conveying certain ſupernatural notices to the ſoul. This is ſuch an overpowering impreſſion made of any propoſition upon the mind by God himſelf, as gives an indubitable evidence of the truth and divinity of it.

INSPIRATION, in phyſic, that part of reſpiration, whereby the air is drawn into the lungs, and ſtands contradiſtinguiſhed from exſpiration.

This admiſſion of the air depends immediately on its elaſticity, when the cavity of the breaſt is enlarged by the elevation of the thorax and abdomen, and particularly by the motion of the diaphragm downwards. This dilatation of the breaſt does not draw in the air, though it be a condition abſolutely neceſſary to inſpiration, but it is an actual intruſion of the air into the lungs.

INSPISSATING, INSPISSATION, or CONDENSATION, in pharmacy, the reducing a liquor to a thicker conſiſtence by evaporating the thinner parts. See INCRASSATING.

INSTALLMENT, the inſtating a perſon in any dignity.

The word is derived from the Latin *inſtallo*, which is compounded of *in*, and *ſtallum*, a ſeat in a church, bench in a court of juſtice, &c.

It chiefly denotes the induction of a dean, prebendary, or other eccleſiaſtic dignitary, into the poſſeſſion of his proper ſeat in a cathedral church. This is ſometimes called inſtallation.

INSTALLMENT likewiſe denotes the ceremony, whereby the knights of the garter are placed in their rank in the chapel of St. George at Windſor.

INSTANT, ſuch a part of duration wherein we perceive no ſucceſſion, or it is that which takes up the time of one idea in our minds.

The ſchoolmen diſtinguiſh three kinds of inſtants; a temporary, a natural, and a rational inſtant.

Temporary inſtant is a part of time immediately preceding another: thus the laſt inſtant of a day precedes, immediately and really, the firſt inſtant of the following day.

Natural inſtant is what we otherwiſe call a priority of nature, which obtains in things that are ſubordinated in acting, as firſt and ſecond cauſes, or cauſes and their effects: for the nature of things requires, that if there be a ſecond cauſe there muſt be a firſt; and that there muſt be a cauſe, if there be an effect. See CAUSE.

Rational inſtant is not any real inſtant, but a point which the underſtanding conceives to have been before ſome other inſtant, founded on the nature of the thing which occaſioned it to be conceived: for inſtance, if God made ſeveral things voluntarily, which he could otherwiſe have let alone, there is a reaſonable foundation to conceive God ſuch as he is in himſelf, before he had made any of theſe voluntary determinations: but as there was no real inſtant when God had not formed any determination, this inſtant is called a rational inſtant, by way of oppoſition to an inſtant of time.

INSTAURATION, the re-eſtabliſhment or reſtauration of a religion, a church, or the like, to its former ſtate.

INSTEP, in the manege, is that part of a horſe's hind leg which reaches from the ham to the paſtern-joint; and which, when the horſe is in his natural poſture of ſtanding, ſhould be large, flat, and in a perpendicular line with the ground: for when the inſteps do not ſtand perpendicularly, it is a certain ſign of weakneſs either in the reins or hinder quarters.

INSTINCT, an appellation given to the ſagacity and natural inclinations of brutes, which ſupplies the place of reaſon in mankind. See the articles REASON and BRUTE.

INSTITUTES, in literary hiſtory, a book containing the elements of the Roman law, and conſtitutes the laſt part of the civil law. See CIVIL LAW.

INSTITUTION, in general, ſignifies the eſtabliſhing or founding ſomething.

INSTRUMENT, in general, whatever is ſubſervient to a cauſe in producing any effect.

A common caſe of mathematical inſtruments contains ſeveral compaſſes, a ſector, ſcale, drawing-pen, and protractor. See the articles COMPASSES, SECTOR, SCALE, &c.

INSTRUMENT, in law, ſome public act, or authentic deed, by which any truth is made apparent, or any right or title eſtabliſhed in a court of juſtice. See the article DEED.

INSULATED, *Inſulatus*, in architecture, an appellation given to ſuch columns as ſtand alone, or free from any contiguous wall, &c. like an iſland in the ſea, whence its name.

INSULT, *Inſultus*, in medicine, ſignifies the acceſs of the paroxyſm of intermitting diſeaſes.

INSULT, in the art of war, the ſame with aſſault. See ASSAULT.

INSURANCE, or ASSURANCE, a contract or ſecurity, which is commonly called policy, given by one or more perſons, whereby they oblige themſelves, in conſideration of a ſum of money paid down, to make good ſhips, merchandizes, houſes, &c. to the value of that for which the premium is received, in caſe of loſs by ſtorm, pirates, fire, &c.

We have in London ſeveral offices of inſurance from fire, which are erected into corporations, as the Royal Exchange-aſſurance, the Sun-fire-office, the Hand in-Hand fire-office, the London-aſſurance, the Phœnix-office, &c. ſome for houſes, others for goods, and ſome for both.

There are alſo offices wherein private merchants grant inſurances for ſhips, and theſe are called inſurance-brokers.

We have alſo aſſurances for life, by virtue of which, when the perſon aſſured dies, a ſum of money, according as he inſured, becomes payable to the perſon in favour of whom the policy of aſſurance was granted. See POLICY *of Aſſurance*.

INTACTÆ, in conics, an appellation ſometimes given to the aſymptotes. See the article ASYMPTOTES.

INTAGLIOS, precious ſtones on which are engraved the heads of great men, inſcriptions, and the like; ſuch as we frequently ſee ſet in rings, ſeals, &c.

INTEGER, in arithmetic, a whole number, in contradiſtinction to a fraction. See NUMBER and FRACTION.

INTEGRAL, or INTEGRANT, in the ſchools, denotes thoſe parts which are neceſſary to the integrity of any whole, and ſo ſtand contradiſtinguiſhed from eſſential parts. The arms, &c. are integral parts of a man; body and ſoul are eſſential parts.

INTEGRAL *Calculus*, in the new analyſis, is the counter part to the differential calculus. The latter hath been fully explained by M. l'Hoſpital; but the former hath been but little cultivated.

The integral calculus of Leibnitz and others anſwers to the inverſe method of fluxions among the Engliſh. See FLUXIONS.

INTENDMENT, in law, is the intention, deſign, or true meaning of a perſon or thing, which frequently ſupplies what is not fully expreſſed: but though the intent of parties in deeds and contracts is much regarded by the law, yet it cannot take place againſt the rules of law.

INTENDMENT *of Crimes*; this in caſe of treaſon, where the intention is proved by circumſtances, is puniſhable in the ſame manner as if it was put in execution.

INTERCALARY DAY, in chronology, the odd day inſerted in a leap-year. See the article BISSEXTILE.

The word is Latin, *intercalaris*, and derived from *inter*, and *calo*, which anciently ſignified to call with a loud voice: an intercalary day among the Romans, ſignifying a day inſerted between two other days, which for that reaſon was proclaimed by the prieſts with a loud voice.

INTERCEPTED AXIS, in conic ſections, the ſame with abſciſs. See ABSCISS.

INTERCOLUMNIATION, in architecture, implies the ſpace between two columns, which is always to be proportioned to the height and bulk of the columns.

INTERCOMMONING, in law, is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, cauſed their cattle to feed promiſcuouſly on them.

INTERCOSTAL, in anatomy, an appellation given to ſuch muſcles, nerves, arteries, and veins, as lie between the ribs. See RIB.

INTERDICT, an eccleſiaſtical cenſure, by which the church of Rome forbids the performance of divine ſervice in a kingdom, province, town, &c.

INTEREST, a ſum of money which is reckoned for the loan and forbearance of ſome other ſum lent for, or due at, a certain time, according to a certain rate in the hundred pounds. The ſum lent or forborne is called the principal, becauſe it produces the intereſt, or from which the intereſt is reckoned. Intereſt is either ſimple or compound.

Simple INTEREST is that which is paid for the loan of any principal or ſum of money lent out for ſome time at any rate, per cent. agreed on between the borrower and the lender; which, according to the laws of England, ought to be but 5 l. for the uſe of 100 l. for one year, and 10 l. for the uſe of 100 l. for two years; and ſo on for a greater or leſs ſum, proportionable to the time propoſed.

There are ſeveral ways of computing or anſwering queſtions about ſimple intereſt; as by the ſingle and double rule of three; others make uſe of tables compoſed of ſeveral rates per cent.

But we ſhall ſhew, that all computations, relating to ſimple intereſt, are grounded upon arithmetical progreſſion; and from thence raiſe ſuch general theorems as will ſuit with all caſes. In order to that,

Let $\begin{cases} P = \text{any principal or ſum put to intereſt.} \\ R = \text{the ratio of the rate per cent. per annum.} \\ t = \text{the time of the principal's continuing at intereſt.} \\ A = \text{the amount of the principal and its intereſt.} \end{cases}$

Note. The ratio of the rate is only the ſimple intereſt of 1 l. for one year, at any given rate; and it is found thus: viz.

100 : 5 : : 1 : 0.05 = the rate at 5 per cent. per annum.
100 : 6 : : 1 : 0.06 = the rate at 6 per cent. &c. Again,
100 : 6.5 : : 1 : 0.065 = the ratio 6 and $\frac{1}{2}$ per cent.

And if the given time be whole years, then t = the number of thoſe years: but if the time given be either pure parts of a year, or parts of a year mixed with years, thoſe parts muſt be turned into decimals; and then t = thoſe decimals, &c.

Now

Now the common parts of a year may be eaſily turned or converted into decimal parts, if it be conſidered,

That one { Day is the $\frac{1}{365}$ part of a year = 0.00274. / Month is the $\frac{1}{12}$ part of a year = 0.08333. / Quarter is the $\frac{1}{4}$ of a year = 0.25.

Half a year = 0.5, and three quarters = 0.75.

Theſe things being premiſed, we may proceed to raiſing the theorems:

Let R = the intereſt of 1 l. for one year, as before.

Then 2 R = the intereſt of 1 l. for two years.

And 3 R = the intereſt of 1 l. for three years.

4 R = the intereſt of 1 l. for four years; and ſo on for any number of years propoſed.

Hence it is plain that the ſimple intereſt of 1 l. is a ſeries of terms in arithmetical progreſſion increaſing, whoſe firſt term and common difference is R; and the number of all the terms is t: therefore the laſt term will always be tR = the intereſt of 1 l. for any given time ſignified by t.

Then { As 1 l. is to the intereſt of 1 l. ſo is any principal or given ſum to its intereſt.

That is, 1 l. : tR :: P : tR P = the intereſt of P. Then the principal being added to its intereſt, their ſum will be = A, the amount required: which gives this general theorem:

Theorem tR P + P = A.

From whence the three following theorems are eaſily deduced.

Theorem 2. $\frac{A}{tR+1} = P.$

Theorem 3. $\frac{A-P}{tP} = R.$

Theorem 4. $\frac{A-P}{RP} = t.$

Theſe four theorems reſolve all queſtions about ſimple intereſt. Thus if it were to be required to find what 256 l. 10 s. will amount to in three years, one quarter, two months, and eighteen days, at 6 per cent. per annum.

Here is given P = 256.5, R = 0.06, and t = 3.46599. Quere A, per theorem 1.

For three years = 3.
One quarter = 0.25
Two months = 0.16667 = 0.08333 × 2
Eighteeen days = 0.04932 = 0.00274 × 18

Hence t = 3.46599: × 0.06 = 0.2079594 = tR.
Then 0.207594 × 256.5 = 53.341586 = t R P.
And 53.341586 + 256.5 = 309.841586 = tR P + P = A.
That is, 309.841586 = 309 l. 16 s. 10 d. being the anſwer required.

And thus may all queſtions, relating to ſimple intereſt, be reſolved, due regard being had to the theorem relating to the queſtion.

Annuities, or penſions in arrears, may be computed by ſimple intereſt, as follows.

When annuities, payable yearly, half yearly, &c. are not paid as they become due, ſuch annuities are ſaid to be in arrears; and, therefore, to find the value of an annuity in arrears, we muſt calculate what all thoſe payments will amount to, allowing any rate of ſimple intereſt for their forbearance, from the time each particular payment became due. In order to this, put u = the annuity, t = the time it has continued unpaid, R = the ratio, or intereſt for 1 l. for one year, and A = the amount of the annuity and its intereſt.

Then if u = the firſt year's rent due with intereſt, Ru will = the intereſt, and 2 u = the rent due at the end of the ſecond year: and conſequently, 2Ru = the intereſt, and 3u = the rent due at the end of the third year; and 3Ru = the intereſt, and 4 u = the rent due at the end of the fourth year: and ſo on for any number of years.

Hence it is evident, that Ru + 2Ru + 3Ru + 4Ru + 5u = A, the ſum of all their rents and their intereſts being forborn five years: from whence it follows, that Ru + 2Ru + 3Ru + 4Ru = A − tu. Here t = 5. Divide the equation by u, and we have R + 2R + 3R + 4R = $\frac{A-tu}{u}$. In order to find the ſum of this progreſſion, put z = R + 2R + 3R + 4R, &c. Then 1 + 2 + 3 + 4, &c. = $\frac{z}{R}$. Here the ſum of the firſt and laſt terms is 4 + 1 = 5 = t. And the number of all the terms is 4 = t − 1: therefore $\frac{t-1}{2} \times t$ = the ſum of all the terms. That is, $\frac{tt-t}{2} = \frac{Z}{R}$. Hence $\frac{ttR-tR}{2} = z$. Conſequently $\frac{ttR-tR}{2} = \frac{A-tu}{u}$.

From this equation the three following theorems are eaſily and naturally deduced.

Theorem 1. $\frac{ttRu-tRu+2tu}{2} = A.$ Or, $\frac{ttu-tu}{2} \times R : + tu = A.$

Theorem 2. $\frac{2A}{ttR+tR+2t} = u.$ Theorem 3. $\frac{2A-2tu}{ttu-tu} = R.$ Let $\frac{2}{R} = x + 1.$ Then $t = \sqrt{\frac{2A}{Ru} + \frac{xx}{4}} - \frac{1}{2}x.$ Theorem 4.

By the help of theſe four theorems, all queſtions of this nature may be eaſily ſolved. Thus for example:

Suppoſe 250 l. yearly annuity, be forborn or unpaid ſeven years, what will it amount to in that time at ſix per cent. for each payment as it becomes due?

Here u = 250, t = 7, and R = 0,06, are given, to find A; which is eaſilyperformed by theorem 1. For, firſt 250 × 7 = 1750 = tu; and 1750 × 7 = 12250 = ttu. Again, 12250 − 1750 = 10500 = ttu − tu. And $\frac{10500}{2}$ × 0,06 = 315. Laſtly, 315 + 1750 = A = 2065 l. the anſwer required.

Having ſhewn the method of finding the value of annuities in arrears, we ſhall proceed to explain the manner of finding the preſent worth of annuities, computed at ſimple intereſt.

The whole buſineſs of purchaſing annuities, or taking of leaſes, &c. for any aſſigned time, depends upon the purchaſe, with the annuity or yearly rent, by allowing the ſame rate of intereſt to both parties, which may be eaſily performed by carefully attending to what has been already ſaid. For example, What is 75 l. yearly rent, to continue nine years, worth in ready money at 6 per cent. per ann. ſimple intereſt?

Firſt, by theorem 1, find what the propoſed yearly rent would amount to, if it were forborn nine years at 6 per cent. which by the ſaid theorem will amount to 837 = A.

Then find what principal being put out to intereſt, for the ſame time, and at the ſame rate, will amount to 837 l. = A.

Thus tR = 0.54 = 9 × 0.06, tR + 1 = 1.54, by which divide 837, and we have 543.5064 = 543 l. 10 s. 1 d. $\frac{1}{2}$, the preſent worth of the annuity required.

Compound INTEREST is that which ariſes from any principal and its intereſt put together, as the intereſt ſtill becomes due; ſo that at every payment, or at the time when the payments become due, there is created a new principal; and for that reaſon it is called intereſt upon intereſt, or compound intereſt.

As for inſtance, ſuppoſe 100 l. were lent out for two years at 6 per cent. per annum, compound intereſt; then at the end of the firſt year, it will only amount to 106 l. as in ſimple intereſt. But for the ſecond year this 106 l. becomes principal, which will amount to 112 l. 7 s. 2 d. $\frac{1}{2}$. at the ſecond year's end; whereas by ſimple intereſt it would have amounted to but 112 l. And although it be not lawful to let out money at compound intereſt, yet in purchaſing annuities or penſions, &c. and taking leaſes in reverſion, it is very uſual to allow compound intereſt to the purchaſer for his ready money, and therefore it is very requiſite to underſtand it.

Let R be the amount of one pound in one year, viz. principal and intereſt; P any ſum put out at intereſt for any number n of years, a its amount, A any annuity forborn n years, m its amount, and v its worth in preſent money, for the ſame time.

Therefore, ſince one pound put out at intereſt, in the firſt year is increaſed to R, it will be as 1 to R, ſo is R, the ſum forborn the ſecond year, to R^2, the amount of one pound in two years; and therefore as 1 to R, ſo is R^2, the ſum forborn the third year, to R^3, the amount in three years: whence it appears that R^n, or R, raiſed to the power whoſe exponent is the number of years, will be the amount of one pound in thoſe years: but as 1 l. to its amount R^n, ſo is P to a its amount in the ſame time; whence we have P × R^n = a. And becauſe the amount of one pound in n years is R^n, its increaſe in that

time will be R^n-1; but its intereſt for one ſingle year, or the annuity anſwering to that increaſe, is $R-1$; therefore as $R-1$ to R^n-1, ſo is A to m. Hence we get $\frac{A\times R^n-1}{R-1}=m$. But as it appears that one pound, ready money, is equivalent to R^n, to be received at the expiration of n years, we have as R^n to 1, ſo is $\frac{A\times R^n-1}{R-1}$ (the ſum in arrear) to v, its preſent worth in ready money; whence $\frac{A\times 1-R^{\frac{1}{n}}}{R-1}=v$. From theſe theorems the various queſtions relating to compound intereſt, annuities in arrears, and purchaſing of annuities, are reſpectively reſolved.

Several ingenious mathematicians, as Dr. Halley, De Moivre, Simpſon, &c. have explained the method of computing the expectation or eſtimate of life; we ſhall therefore here ſubjoin a curious and uſeful table, that ſhews the value of annuities for every fifth year of age to the 75th at 3, 4, and 5 per cent. as given by the laſt mentioned gentleman in his Doctrine of Annuities upon Lives.

Age	Year's purch. at 5 per cent.	Year's purch. at 4 per cent.	Year's purch. at 3 per cent.
6	14.1	16.2	18.8
10	14.3	16.4	19.0
15	13.9	15.8	18.3
20	13.0	14.8	17.2
25	12.3	14.0	16.1
30	11.6	13.1	15.0
35	10.9	12.3	14.1
40	10.3	11.5	13.2
45	9.8	10.8	12.3
50	9.2	10.1	11.4
55	8.5	9.3	10.3
60	7.9	8.4	9.2
65	7.1	7.5	8.0
70	6.2	6.5	6.9
75	5.2	5.4	5.6

INTEREST, in law, is generally taken for a chattel real, or a leaſe for years, &c. but more for a future term.

INTERJECTION, in grammar, an indeclinable part of ſpeech, ſignifying ſome paſſion or emotion of the mind.

As the greateſt part of the expreſſions uſed on theſe occaſions are taken from nature alone, the real interjections, in moſt languages, are monoſyllables; and as all nations agree in theſe natural paſſions, ſo do they agree in the ſigns and indications of them, as of love, mirth, &c.

The Greeks confound their interjections with adverbs, and the Hebrews confound them with their adverbs and prepoſitions, calling them all by the general name particle.

INTERIM, a name given to a formulary, or kind of confeſſion of the articles of faith, obtruded upon the proteſtants after Luther's death by the emperor Charles V. when he had defeated their forces; ſo called becauſe it was only to take place in the interim, mean time, till a general council ſhould have decided all points in diſpute between the proteſtants and the Romaniſts.

INTERLOCUTORY ORDER, in law, an order that does not decide the cauſe, but only ſome matter incident thereto, which happens between the beginning and end of a cauſe; as when in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cauſe; which order, not being final, is called interlocutory.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play, to amuſe the ſpectators while the actors ſhift their dreſs, or to give time of changing the ſcenes and decorations.

INTERMITTENT or INTERMITTING FEVERS, ſuch fevers as go off and ſoon return again, in oppoſition to thoſe which are continual. See the article *Intermitting* FEVER.

INTERNAL, in general, denotes whatever is within a thing.

INTERNODIUM, among botaniſts, implies the ſpace between two knots or joints of the ſtalks of barley, oats, and the like plants.

INTEROSSEUS, in anatomy, an appellation given to the muſcles which move the fingers and toes, from their being ſituated between the bones of thoſe parts. See the articles MUSCLE, FLEXOR, &c.

INTERPRETATION, among critics, denotes a ſpurious paſſage, inſerted into the writings of ſome ancient author.

INTERPRETER, in general, denotes a perſon who explains the words or writings of another, ſo as to make them intelligible to thoſe who did not underſtand them before.

INTERREGNUM, the time during which the throne is vacant, in elective kingdoms; for in ſuch as are hereditary, like ours, there is no ſuch thing as an interregnum.

INTERREX, the magiſtrate who governs during an interregnum.

INTERROGATION, *or Point of* INTERROGATION, in grammar, a character of this form (?) ſerving to denote a queſtion.

INTERROGATION, in rhetoric, is a figure, whereby the orator propoſes ſomething by way of queſtion; which, it muſt be owned, greatly enlivens the diſcourſe.

INTERROGATORIES, in law, are queſtions wrote down, and demanded of the witneſſes examined in a cauſe, more eſpecially in the court of chancery.

INTERRUPTION denotes the ſame thing with diſjunction in proportion, and is noted thus (:·:) ſignifying the breaking of the ratio in the middle of four diſcrete proportionals, as A : B :· C : D; that is, as A to B, ſo is C to D.

INTERRUPTION, in rhetoric, when a perſon breaks off his diſcourſe ſuddenly to ſhew ſome paſſion.

INTERSECTION, in mathematics, the cutting of a line or plane by another, or the point or line wherein two lines, or two planes, cut each other.

The word is derived from the Latin *inter*, and *ſeco*, to cut.

The mutual interſection of two planes is a right line. The center of a circle is in the interſection of two diameters, &c. The equinoxes happen, when the ſun is in the interſections of the equator and ecliptic.

INTERSPINALES *Colli*, in anatomy, ſmall fleſhy muſcles of the neck, ariſing from the ſuperior parts of each double ſpinal proceſs of the neck, except of the ſecond vertebra; and inſerted into the inferior parts of all the double ſpines. When theſe muſcles act, they draw the ſpines of the vertebra of the neck nearer each other.

INTERSTELLAR, a word uſed by ſome authors to expreſs thoſe parts of the univerſe that are without and beyond our ſolar ſyſtem.

INTERTIES, in architecture, thoſe ſmall pieces of timber that lie horizontally between the ſommers, or between them and the ſell, or reſon.

INTERTRANSVERSALES *Colli*, in anatomy, certain muſcles ſituated among the tranſverſe apophyſes of the vertebræ: they ariſe from the lower vertebra, and are inſerted into that next above: they are of the ſame ſize and figure with the interſpinales.

INTERVAL, in muſic, the difference between two ſounds, in reſpect of acute and grave; or, that imaginary ſpace terminated by two ſounds, differing in acuteneſs or gravity.

Mr. Euler, in his *Nov. Theor. Muſ.* defines an interval, the meaſure of the difference of an acute and grave ſound: thus, ſuppoſe three ſounds a, b, c, of which c is the moſt acute, a the moſt grave, and b the intermediate ſound. It appears, that the interval between the ſound a and c, is the aggregate of the intervals between a and b, and between b and c. Therefore, if the interval between a and b, be equal to that between b and c, which happens when $a:b::c:d$; the interval between a to c, will be double the interval a to b, or b to c. This being conſidered, it will appear that intervals ought to be expreſſed by the meaſures of the ratios, conſtituting the ſounds forming thoſe intervals: but ratios are meaſured by the logarithms of fractions, the numerators of which denote the acute ſounds,

ſounds, and the denominators the grave. Hence the interval between the ſounds *a* and *b*, will be expreſſed by the logarithm of the fraction $\frac{b}{a}$, which is uſually denoted by L $\frac{b}{a}$; or, which comes to the ſame, by L *b* — L *a*. The interval therefore of equal ſounds, *a* to *a*, will be null, as L *a* — L *a* = *o*. The interval called an octave, or diapaſon, will be expreſſed by the logarithm of 2; and the interval of the fifth or diapente, will be L $\frac{3}{2}$ = L 3 — L 2. From whence it appears, that thoſe intervals are incommenſurable; ſo that no interval, however ſmall, can be an aliquot part, both of the octave and fifth. The like may be ſaid of the intervals L $\frac{4}{3}$ and L $\frac{5}{4}$, and others whoſe logarithms are diſſimilar. But intervals expounded by logarithms of numbers, which are powers of the ſame root, may be compared. Thus the interval of the ſounds 27 : 8, will be the interval of the ſounds 9 : 4, as 3 is to 2: for L $\frac{27}{8}$ = 3 L $\frac{3}{2}$, and L $\frac{9}{4}$ = 2 L $\frac{3}{2}$. Euler. *ibid.* p. 74. But though the logarithms of numbers, which are not powers of the ſame root, be incommenſurable, yet an approximating ratio of ſuch may be found. Thus, the meaſure of the octave is L 2 = 0.3010300, and the meaſure of the fifth is L 3 — L 2 = 0.1760913. Hence the interval of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio being reduced to ſmaller terms, will give us theſe ſimpler expreſſions for the ratio of the octave and fifth, 2 : 1, 3 : 2, 5 : 3, 7 : 4, 12 : 7, 17 : 10, 29 : 17, 41 : 24, 53 : 31, which laſt is very near the truth. Euler. *ibid.* p. 75.

In like manner intervals may be divided into any number of equal parts: for this purpoſe we need only divide the logarithm of the propoſed interval into the ſame number of parts, and then find its correſponding number by the tables. The ratio of the number ſo found, to unity, will give the required ratio of the dividend interval to its propoſed part. Thus let the third part of an octave be required; its logarithm will be = 0.1003433 = $\frac{1}{3}$ L 2: the ratio correſponding nearly to this, will be 63 : 50, or leſs accurately, 29 : 23, or 5 : 4, which laſt expreſſes the third major; and this is by the leſs knowing taken for the third part of an octave, and ſeems to be ſuch on our harpſichord and organs, where from C to E is a third, from E to G♯ another, and from G♯ or A♭ to *c*, another third. But the more intelligent know that G♯ and A♭ ought not to be reputed the ſame ſound, ſince they differ by a dieſis enharmonica, which is nearly equal to two commas.

INTERVALS, in gardening and huſbandry, the ſpaces left between the ſeveral rows of plants ſown or ſet in gardens or fields. See HUSBANDRY.

INTESTATE, in law, a perſon that dies without making a will; in which caſe, a diſtribution of his perſonal eſtate, after his debts and funeral charges are paid, is to be made among the wife and children of the deceaſed, or for want of ſuch, among the next of kin.

INTESTINES, in anatomy, long, cylindrical, hollow, and membranaceous bodies; or rather, one ſuch continued body, or tube, reaching from the ſtomach to the anus.

The ſtructure and ſubſtance of the inteſtines are membranaceous; being formed, in every part, of five coats or tunics. The firſt is the common coat, from the peritonæum, and is membranaceous. The ſecond is cellular, and is called by late writers, tunica celluloſa Ruyſchii: it is continuous with the meſentery, and is to be diſcovered by inflating it: this coat, in flat animals, frequently contains abundance of fat. The third is muſcular; it is compoſed of a double ſeries of fibres, in part longitudinal, and in part annular; and theſe aſſiſt the motion of the guts. The fourth coat is nervous: it is furniſhed with abundance of cellules, vaſcules, and glands, and is thicker than the others: from this ariſe the rugæ, and the valves of the inteſtines. The fifth is the villoſe coat, which ſuſtains the terminations of the excretory veſſels, and the beginnings of the lacteals: hence, when nicely examined, it has the appearance of a ſieve: it is the organ of percolation of the chyle.

The inteſtines have veſſels in great abundance, running over every part of their ſubſtance. Their arteries are from the meſeraic ones; the upper meſeraic ſerving for the ſmaller inteſtines, the lower for the larger; and theſe make a multitude of very ſingular and ſuprizing anaſtomoſes. The veins are meſeraics, and go off to the vena portæ and the liver. The nerves are ſent from the intercoſtals, and the par vagum. And beſide theſe we are to obſerve the lacteal veſſels. See the article LACTEAL.

The rectum, it is to be obſerved, receives blood-veſſels alſo from the hypogaſtrics. There are alſo, beſides the Brunnerian glands of the duodenum, other glands in the inteſtines, called from the name of the perſon who diſcovered them, glandulæ Peyeri. Theſe, in the ſmall guts, are uſually little, congregrate, and miliary; but ſometimes they are ſingle. They are larger as they are nearer to the duodenum, and ſmaller as they approach towards the great guts. Their office is to diſcharge into the inteſtines a liquor, which ſerves for the attenuation of the chyle, and for the lubricating of the inteſtines. In the larger guts, and in the vermiform appendage, they are ſingle and large, of a lenticular figure; and they are largeſt of all in the rectum. They have mouths, out of which there is ſecreted a fluid, which ſerves to lubricate the ſides of the inteſtines, and to ſoften the fæces, that they may be evacuated without pain.

The uſe of the ſmaller guts is to promote the formation of the chyle, to perfect its ſecretions, and to propel the remaining fæces to the larger. The office of the larger guts is to receive and collect the matter of the fæces, and at a proper time to expel it. See CHYLE.

INTESTINAL, ſomething belonging to, or ſeated in the inteſtines.

INTRADA, ENTRY, in the Italian muſic, is much the ſame with prelude or overture.

INTRENCHMENT, or RETRENCHMENT, in the art of war. See the article RETRENCHMENT.

INTRIGUE, or INTREAGUE, an aſſemblage of events or circumſtances, occurring in an affair, and perplexing the perſons concerned in it.

In this ſenſe, it is uſed to ſignify the nodus or plot of a play or romance; or that point wherein the principal characters are moſt embarraſſed, through the artifice and oppoſition of certain perſons, or the unfortunate falling out of certain accidents and circumſtances.

In tragedy, or an epic poem, there are always two deſigns; the firſt and principal is that of the hero of the piece. The ſecond contains the deſigns of all thoſe who oppoſe him: theſe oppoſite cauſes produce oppoſite effects; to wit, the efforts of the hero for the execution of his deſign, and the efforts of thoſe who thwart it. As thoſe cauſes and deſigns are the beginning of the action, ſo theſe efforts are the middle, and there form a knot or difficulty which we call the intrigue, that makes the greateſt part of the poem. It laſts as long as the mind of the reader or hearer is ſuſpended about the event of thoſe oppoſite efforts: the ſolution or cataſtrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up.

INTRINSIC, a term applied to the inner, real, and genuine values, properties, &c. of any thing, in oppoſition to their extrinſic or apparent values, &c.

INTRUSION, in law, obtains where an anceſtor dies ſeiſed of an eſtate, or inheritance, which is expectant upon an eſtate for life, and the tenant for life dies; after which a ſtranger enters before the heir, in which caſe he is ſaid to intrude.

INTUITION, among logicians, the act whereby the mind perceives the agreement or diſagreement of two ideas, immediately by themſelves, without the intervention of any other; in which caſe, the mind perceives the truth as the eye doth the light, only by being directed towards it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. See IDEA.

This part of knowledge, ſays Mr. Locke, is irreſiſtible, and, like the ſun-ſhine, forces itſelf immediately to be perceived as ſoon as ever the mind turns its view that way. It is on this intuition that all the certainty and evidence of our other knowledge depends; this certainty every one finds to be ſo great, that he cannot imagine, and therefore cannot require, a greater. See the articles

ticles JUDGMENT, KNOWLEDGE, DEMONSTRATION, &c.

INVALID, a perſon wounded, maimed, or diſabled for action by age, &c.

INVECTED, in heraldry, denotes a thing fluted or furrowed.

INVECTIVE, in rhetoric, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the perſon reproved; whereas the invective is the work of an enemy, and entirely deſigned to vex and give uneaſineſs to the perſon againſt whom it is directed.

INVENTION denotes the act of finding any thing new, or even the thing thus found.

INVENTION, in rhetoric, being one of the ſecond diviſions of invention, according to Bacon, ſignifies the finding out and chooſing of arguments which the orator is to uſe for proving his point, or moving his hearers paſſions.

INVENTION, in poetry, is applied to whatever the poet adds to the hiſtory of the ſubject he has choſen, as well as to the new turn he gives it.

INVENTION, in painting, is the choice which the painter makes of the objects that are to enter the compoſition of his piece.

INVENTORY, in law, &c. is a ſchedule containing all the goods and chattels of a deceaſed perſon that belonged to him at the time of his death, together with the value of the ſame, as appraiſed by two or more indifferent perſons.

INVERSE is applied to a manner of working the rule of three, or proportion, which ſeems to go backward, or contrary to the order of the common or direct rule. See the articles RULE *of Three* and PROPORTION.

INVERSE *Method of Fluxions*. See FLUXIONS.

INVERSION, in grammar, is where the words of a phraſe are ranged in a manner not ſo natural as they might be.

It is a conſiderable beauty either in verſe or proſe, when we have it from an able hand; it gives vigour and variety to a ſentence, and keeps the mind in an agreeable ſuſpence and expectation of a marvellous turn and concluſion.

INVESTIGATION properly denotes the finding any thing out by the prints of the feet.

Mathematicians, &c. have hence applied the word to the reſpective reſearches in which they are employed.

INVESTIGATION *of a Theme*, in grammar, the finding out the primitive ſenſe, mood, and perſon of any verb that is remote from its ſource.

It is abſolutely neceſſary to be acquainted with this method of inveſtigation, in order to underſtand a Greek author.

Clenard was the firſt who introduced the term into grammar.

INVESTITURE, in law, a giving livery of ſeiſin or poſſeſſion.

INVOCATION, in theology, the act of adoring God, and eſpecially of addreſſing him in prayer for his aſſiſtance and protection.

INVOCATION, in poetry, an addreſs at the beginning of a poem, wherein the poet calls for the aſſiſtance of ſome divinity, particularly of his muſe, or the deity of poetry.

INVOICE, an account in writing of the particulars of merchandize, with their value, cuſtom, charges, &c. tranſmitted by one merchant to another in a diſtant country.

One copy of every invoice is to be inſerted verbatim in the invoice-book, for the merchant's private uſe; and another copy muſt, immediately upon ſhipping off the goods, be diſpatched by poſt, or otherwiſe, to the correſpondent. This copy is commonly drawn out upon a ſheet of large poſt paper, to the end of which is ſubjoined a letter of advice.

INVOICE-BOOK. This book is paged, and contains copies of the invoices of goods ſent to ſea: for as a merchant is obliged to ſend his correſpondent an invoice of all the goods he conſigns to him, ſo it is reaſonable that he ſhould keep a copy of it for himſelf.

INVOLUCRUM, among botaniſts, that ſort of calyx, or cup, which ſurrounds a number of flowers together, every one of which has, beſides this general cup, its own particular perianthium.

The involucrum conſiſts of a number of little leaves, diſpoſed in a radiated manner.

INVOLUTION, in algebra, the raiſing any quantity from its root to any height or power aſſigned.

The quantity a^m expreſſes any power of a in general; the exponent (m) being undetermined; and a^{-m} expreſſes $\frac{1}{a^m}$, or a negative power of a of an equal exponent: and $a^m \times a^{-m} = a^{m-m} = a^0 = 1$ is their product, a^0 expreſſes any other power of a; $a^m \times a^n = a^{m \times n}$ is the product of the powers a^m and a^n, and a^{m-n} is their quotient.

To raiſe any ſimple quantity to its 2d, 3d, or 4th power, is to add its exponent twice or four times to itſelf; therefore, the 2d power of any quantity is had by doubling its exponent, and the 3d by trebling its exponent; and in general the power expreſſed by m of any quantity is had by multiplying the exponent by m, as is obvious from the multiplication of powers.

Thus, the 2d power or ſquare of a is $a^{2 \times 1} = a^2$; its third power or cube is $a^{3 \times 1} = a^3$; and the m^{th} power of a is $a^{m \times 1} = a^m$. Alſo the ſquare of a^4 is $a^{2 \times 4} = a^8$; the cube of a^4 is $a^{3 \times 4} = a^{12}$; and the m^{th} power of a^4 is $a^{4 \times m}$. The ſquare of abc is $a^2 b^2 c^2$, the cube is $a^3 b^3 c^3$, the m^{th} power $a^m b^m c^m$.

The co-efficient muſt alſo be raiſed to the ſame power by a continual multiplication of itſelf, as often as an unit by itſelf, is contained in the exponent of the power required. Thus the cube of $3ab$ is $3 \times 3 \times 3 \times a^3 b^3 = 27 a^3 b^3$.

As to the ſigns when the quantity to be involved is poſitive, it is obvious that all its powers muſt be poſitive. And, when the quantity to be involved is negative, yet all its powers whoſe exponents are even numbers muſt be poſitive; for any number of multiplications of a negative, if the number is even, gives a poſitive.

The power then only can be negative, when its exponent is an odd number, though the quantity to be involved be negative.

The powers of $-a$ are $-a$, $+a^2$, $-a^3$, $+a^4$, $-a^5$, &c.

Thoſe whoſe exponents are 2, 4, 6, &c. are poſitive; but thoſe whoſe exponents are 1, 3, 5, &c. are negative.

The involution of compound quantities is a more difficult operation. The powers of any binomial $a+b$ are found by a continual multiplication of it by itſelf; as follows:

$a + b =$ the root.

$\times\ a + b$

$a^2 + ab$

$+ ab + b^2$

$a^2 + 2ab + b^2 =$ the ſquare or 2d power.

$\times\ a + b$

$a^3 + 2a^2 b + ab^2$

$+ a^2 b + 2ab^2 + b^3$

$a^3 + 3a^2 b + 3ab^2 + b^3$

$\times\ a + b$

$a^4 + 3a^3 b + 3a^2 b^2 + ab^3$

$+ a^3 b + 3a^2 b^2 + 3ab^3 + b^4$

$a^4 + 4a^3 b + 6a^2 b^2 + 4ab^3 + b^4 =$ the biquadrate or 4th power.

If the powers of $a-b$ are required, they will be found the ſame as the preceding, only the terms in which the exponent of b is an odd number will be found negative; becauſe an odd number of multiplications of a negative produces a negative. Thus the cube of $a-b$ will be found to be $a^3 - 3a^2 b + 3ab^2 - b^3$; where the 2d and 4th terms are negative, the exponent of b being an odd number in theſe terms. In general, the terms of any power of $a-b$ are poſitive and negative by turns.

If it be obſerved, that, in the firſt term of any power of $a \mp b$, the quantity a has the exponent of the power required; that, in the following terms, the exponents of a decreaſe gradually by the ſame difference (viz. an unit) and that in the laſt terms it is never found; the powers of b are in the contrary order: it is not found in the firſt term, but its exponent in the 2d term is an unit, in the

3d term its exponent is 2; and thus its exponent increaſes, till in the laſt term it becomes equal to the exponent of the power required.

As the exponents of a thus decreaſe, and at the ſame time thoſe of b increaſe, the ſum of their exponents is always the ſame, and is equal to the exponent of the power required.

To find the co-efficient of any term, the co-efficient of the preceding term being known, you are to divide the co-efficient of the preceding term by the exponent of b in the given term, and to multiply the quotient by the exponent of a in the ſame term, increaſed by an unit.

In general, if $a + b$ is to be raiſed to any power m, the terms, without their co-efficients, will be a^m, $a^{m-1}b$, $a^{m-2}b^2$, $a^{-3}b^3$, $a^{m-4}b^4$, $a^{m-5}b^5$, &c. continued till the exponent of b becomes equal to m.

The co-efficients of the reſpective terms, according to the laſt rules, will be $1, m, m \times \frac{m-1}{2}, m \times \frac{m-1}{2} \times \frac{m-2}{3}, m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4}, m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times \frac{m-4}{5}$, &c. continued until you have one co-efficient more than there are units in m.

JOACHIMITES, in church hiſtory, the diſciples of Joachim, a Ciſtercian monk, who was an abbot of Flora in Calabria, and a great pretender to inſpiration.

The Joachimites were particularly fond of certain ternaries: the Father, they ſaid, operated from the beginning till the coming of the Son; the Son, from that time to theirs, which was the year 1260; and from that time the Holy Spirit was to operate in his turn. They alſo divided every thing relating to men, to doctrine, and the manner of living, into three claſſes, according to the three perſons in the Trinity: the firſt ternary was that of men; of whom the firſt claſs was that of married men, which had laſted during the whole period of the Father; the ſecond was that of clerks, which had laſted during the time of the Son; and the laſt was that of the monks, in which there was to be an uncommon effuſion of grace by the Holy Spirit: the ſecond ternary was that of doctrine, viz. the Old Teſtament, the New, and the everlaſting Goſpel; the firſt they aſcribed to the Father, the ſecond to the Son, and the third to the Holy Spirit: a third ternary conſiſted in the manner of living, viz. under the Father, men lived according to the fleſh; under the Son, they lived according to the fleſh and the ſpirit; and under the Holy Ghoſt, they were to live according to the ſpirit only.

JOB, or *Book of* JOB, a canonical book of the Old Teſtament, containing a narrative of a ſeries of misfortunes which happened to a man whoſe name was Job, as a trial of his virtue and patience; together with the conferences he had with his cruel friends, on the ſubject of his misfortunes, and the manner in which he was reſtored to eaſe and happineſs. This book is filled with thoſe noble, bold, and figurative expreſſions, which conſtitute the very ſoul of poetry.

Many of the Jewiſh rabbins pretend that this relation is altogether a fiction: others think it a ſimple narrative of a matter of fact, juſt as it happened: while a third ſort of critics acknowledge that the ground-work of the ſtory is true, but that it is wrote in a poetical ſtrain, and decorated with peculiar circumſtances, to render the narration more profitable and entertaining.

The time is not ſet down, in which Job lived. Some have thought that he was much ancienter than Moſes, becauſe the law is never cited by Job or his friends, and becauſe it is related that Job himſelf offered ſacrifices. Some imagine that this book was wrote by himſelf; others ſay, that Job wrote it originally in Syriac or Arabic, and that Moſes tranſlated it into Hebrew: but the rabbins generally pronounce Moſes to be the author of it, and many Chriſtian writers are of the ſame opinion.

JOBBER, in law, a perſon that buys and ſells cattle for others. Hence ſtock-jobbers are perſons who buy and ſell ſtocks for other perſons.

IOGUIS, among the Eaſt-Indians, a kind of hermits, who generally ſtand under trees, or near their pagods. Some of them go ſtark naked, holding their arms acroſs over their heads, and continue in that poſture all their lives: others lie on the ground, with one leg higher than the other, and their arms raiſed above their head; and theſe wretched penitents inſenſibly loſe the uſe of their arms and legs: ſome confine themſelves in cages, ſet on the top of a thick ſtake, fixed in the ground, and theſe cages are ſo ſmall, that they put the penitent to prodigious torture: ſome holding a ſabre in one hand, and a kind of ſhield in the other, go up a kind of crane, where hooking themſelves to an iron, which runs a conſiderable way into their backs, they ſpring forward into the air, flouriſhing their ſabres, and launching out into extravagant praiſes of their idols: and others plunge into the Ganges, in hopes of being devoured by a crocodile, fancying that by this means they ſhall obtain the happineſs of the next life.

Theſe miſerable wretches are conſidered by the Indians as perfect models of piety and holineſs: they are followed by perſons of both ſexes, who make a vow of devoting themſelves to their ſervice, and are wholly employed in ſoothing their voluntary ſufferings by offering them alms and refreſhments. They call the pious to their devotions by ringing a little bell; and when they hold their ſpiritual converſations, they ſit cloſe in a ring, and ſet up a banner, made of ſeveral pieces of ſtuff, faſtened at the end of a ſtick.

JOHN, or *Goſpel of St.* JOHN, a canonical book of the New Teſtament, containing a recital of the life, actions, doctrine, and death of our Saviour Jeſus Chriſt, written by St. John the apoſtle and evangeliſt. See the article GOSPEL.

St. John wrote his goſpel at Epheſus, after his return from the Iſle of Patmos, at the deſire of the Chriſtians of Aſia. St. Jerom ſays, he would not undertake it, but on condition they ſhould appoint a public faſt, to implore the aſſiſtance of God; and that the faſt being ended, St. John, filled with the Holy Ghoſt, broke out into theſe words, "In the beginning was the word, &c." The ancients aſſign two reaſons for this undertaking: the firſt is, becauſe, in the other three goſpels, there was wanting the hiſtory of the beginning of Jeſus Chriſt's preaching, till the impriſonment of John the Baptiſt; which, therefore, he applied himſelf particularly to relate. The ſecond reaſon was, in order to remove the errors of the Corinthians, Ebionites, and other ſects.

St. JOHN'S DAY, the name of two Chriſtian feſtivals, one obſerved on the twenty-fourth of June, kept in commemoration of the wonderful circumſtances attending the birth of St. John the Baptiſt; and the other on the twenty-ſeventh of December, in honour of St. John the Evangeliſt.

St. JOHN'S WORT, a plant called by authors hypericum. See HYPERICUM.

JOINDER, or JOYNDER, in law, ſignifies the joining of two perſons in one ſuit againſt another; as for inſtance, if there are two joint-poſſeſſors of goods, and theſe are taken from one of them, they may both join in an action to recover them.

JOINERY, the art of working in wood, or of fitting various pieces of timber together.

JOINT, in general, denotes the juncture of two or more things.

The joints of the human body are called by anatomiſts articulations. See ARTICULATION.

The term joint is alſo applied to the ſeparation between the ſtones or bricks of a building, uſually filled with mortar, plaſter, or cement: alſo by carpenters, to the ſeveral manners of aſſembling or fitting pieces of wood together; as a dove-tail joint, &c.

Stiffneſs of the JOINTS, in ſurgery and medicine, ſometimes proceeds from the bones being broken, bruiſed, or wounded, eſpecially about the extreme parts, which being kept in one poſture, in order for cure, the ſynovia of the joints becomes thick, and depraves or quite aboliſhes its motion; or it may proceed from the bony juice proceeding from broken bones, and inſinuating itſelf into the joint. Hoffman ſays, diſeaſes of the joints ſometimes proceed from ſpaſms of the ligament.

JOINT-EXECUTORS, in law, are when two or more perſons are appointed ſuch by will; in which caſe they are accounted but as one ſingle perſon; ſo that the actions done by one of them are taken to be the acts of all, becauſe they all repreſent the perſon of the teſtator.

JOINT LIVES, in law, is where any thing is granted or given to two or more during their lives.

JOINT-TENANTS are ſuch as hold lands or tenements jointly by one title; as where a man grants lands, &c. to perſons and their heirs; ſuch perſons, during their joint tenancy, muſt jointly plead, as well as be jointly ſued, which is common to them with coparceners of lands.

JOINTURE, in law, generally implies a ſettlement of lands and tenements made on a woman in conſideration of marriage.

It alſo ſignifies a covenant, by which the huſband, or ſome friends of his, aſſures lands, &c. to his wife, for the term of her life.

JOINTURESS, or JOINTRESS, the perſon on whom a jointure is ſettled.

JOISTS, or JOYSTS, in architecture, thoſe pieces of timber framed into the girders and ſommers, on which the boards of the floor are laid.

Joiſts are from ſix to eight inches ſquare, and ought ſeldom to lie at a greater diſtance from each other than ten, or at moſt twelve inches, nor ought they ever to bear a greater length than ten feet, or to be leſs into the wall than eight inches. All joiſts on the back of a chimney ought to be laid with a trimmer, at ſix inches diſtance from the back.

Some carpenters furr their joiſts, as they call it; that is, they lay two rows of joiſts, one over another, the undermoſt of which are framed level with the under ſide of the girder; and the uppermoſt, which lie croſs the lower ones, lie level with the upper ſide of the girder.

JONAH, or *Prophecy of* JONAH, a canonical book of the Old Teſtament, in which is related, that Jonah was ordered to go and propheſy the deſtruction of the Ninevites; but that diſobediently attempting a voyage another way, he was diſcovered by the riſing of a ſudden tempeſt, and caſt into the ſea, where he was ſwallowed up by a whale, which having lodged him three days and three nights in his belly, diſgorged him upon the ſhore; whereupon being ſenſible of his paſt danger and ſurpriſing deliverance, he betook himſelf to the journey and embaſſy to which he was appointed; and arriving at Nineveh, the metropolis of Aſſyria, he, according to his commiſſion, boldly laid open to the inhabitants, their ſins and miſcarriages, and proclaimed their ſudden overthrow; upon which the whole city, by prayer and faſting, and a ſpeedy repentance, happily averted the divine vengeance, and eſcaped the threatened ruin.

IONIC ORDER, the third of the five orders of architecture, being a kind of mean between the robuſt and delicate orders. See plate XLIII. *fig.* 3.

The firſt idea of this order was given by the people of Ionia, who, according to Vitruvius, formed it on the model of a young woman of an elegant ſhape, dreſſed in her hair; whereas the Doric had been formed on the model of a ſtrong robuſt man. The Ionic order is diſtinguiſhed from the Compoſite, in that it has none of the acanthus-leaves in its capital; and from the Tuſcan and Doric, by the channels and flutings in its ſhaft.

The capital of this order is adorned with volutes, and its corniche with dentiles. The proportions of the Ionic pillar, as they are taken from the famous one in the temple of Fortuna Virilis at Rome, now the church of St. Mary the Egyptian, are theſe: 1. The entire order from the ſuperficies of the area to the corniche, are twenty-two modules, or eleven diameters. 2. The column with its baſe contains eighteen modules. 3. The entablature contains four modules. 4. The volute of the capital is of an oval form. 5. The columns in this order are often hollowed, and furrowed with twenty-four gutters or channels, called flutings: theſe flutings are not always concave from the top of the ſhaft to the bottom, but for that third of it next the baſe, they are filled up with a kind of rods or canes; and in the other two thirds they are left hollow, or ſtriated, in imitation of the folds or plaits of a garment.

When this order was firſt invented, its height was but ſixteen modules; but the ancients, to render it ſtill more beautiful than the Doric, augmented its height, by adding a baſe to it.

Mr. Le Clerc makes its entablement four modules and ten minutes, and its pedeſtal ſix entire modules; ſo that the whole order makes twenty-eight modules ten minutes.

This order is at preſent uſed properly in churches and religious houſes, courts of juſtice, and other places of tranquility and devotion.

This order has one advantage above any of the reſt, which conſiſts in this, that the fore and hind parts of its capital are different from its ſides; but this is attended with an inconvenience, when the ordonnance is to turn from the front of the building to the ſide; to obviate which, the capital may be made angular, as is done in the temple of Fortuna Virilis.

Scamozzi, and ſome other modern architects, have introduced the upper part of the Compoſite capital, in lieu of the Ionic, imitating that of the temple of Concord, whoſe four ſides are alike. To render it a little more beautiful, the volute may be made a little oval and inclining.

For the baſe, corniche, freeze, and pedeſtal of this order, ſee the articles BASE, CORNICHE, &c.

IONIC DIALECT, in grammar, a manner of ſpeaking peculiar to the people of Ionia.

IONIC SECT was the firſt of the ancient ſects of philoſophers; the others were the Italic and Ileatic. The founder of this ſect was Thales, who being a native of Miletus in Ionia, occaſioned his followers to aſſume the appellation of Ionic: Thales was ſucceeded by Anaximander, and he by Anaximenes, both of Miletus; Anaxagoras Clazomenius ſucceeded them, and removed his ſchool from Aſia to Athens, where Socrates was his ſcholar. It was the diſtinguiſhing tenet of this ſect that water was the principle of all natural things.

IONIC TRANSMIGRATION was anciently a very celebrated epocha; it took its riſe from the retreat of the Athenian colonies, who upon the death of Codrus, put themſelves under the command of his ſon Neleus, and eſtabliſhed the twelve cities of Ionia in Aſia. Theſe colonies, according to Eratoſthenes, were eſtabliſhed fifty years after the return of the Heraclidæ; and, according to Marſham, ſeventy-ſeven years after the taking of Troy.

JOSHUA, a canonical book of the Old Teſtament, containing a hiſtory of the wars and tranſactions of the perſon whoſe name it bears. This book may be divided into three parts; the firſt of which is a hiſtory of the conqueſt of the land of Canaan; the ſecond, which begins at the twelfth chapter, is a deſcription of that country, and the diviſion of it among the tribes; and the third, compriſed in the two laſt chapters, contains the renewal of the covenant he cauſed the Iſraelites to make, and the death of their victorious leader and governor. The whole comprehends a term of ſeventeen, or, according to others, of twenty-ſeven years.

JOURNAL, a day-book, regiſter, or account of what paſſes daily.

JOURNAL, or DAY-BOOK, among merchants, is that wherein the tranſactions recorded in the waſte-book, are prepared to be carried to the ledger, by having their proper debtors and creditors aſcertained and pointed out; for a more diſtinct account of which ſee the article BOOK-KEEPING.

JOURNAL, among ſeamen, a certain diary, or daily compact, of the occurrences that happen from noon to noon in the courſe of the voyage, as winds, weather, ſetting and ſhifting of ſails, and remarking the various courſes and diſtances run, which are reduced into one, and corrected by a ſolar obſervation. Every thing material that happens to the ſhip or her crew is alſo obſerved particularly in this journal.

IPECACUANHA, in pharmacy, a ſlender root, brought from the Spaniſh Weſt-Indies, in ſhort pieces, variouſly bent and contorted, full of wrinkles and deep circular fiſſures, which reach quite down to a ſmall whitiſh woody fibre, that runs in the middle of each piece: the cortical part is compact, brittle, and looks ſmooth and reſinous on breaking. Two ſorts of this root are met with in the ſhops, one brought from Peru, the other from Braſil; uſually denominated from their external colour, the firſt whitiſh, grey, or aſh-coloured, the other brown. The firſt is generally preferred, being found to operate with the greateſt certainty and mildneſs.

A root has been brought over under the name of white ipecacuanha, which has little or nothing of the virtues of the two foregoing: this is eaſily diſtinguiſhed by its yellowiſh

yellowiſh white colour, woody texture, and having no fiſſures or wrinkles. More dangerous abuſes have ſometimes been committed, by the ſubſtitution or mixture of the roots of an American apocynum, which have been found to operate with great violence, both upwards and downwards, and in ſome inſtances, as is ſaid, to prove fatal: theſe may be known by their being larger than the true ipecacuanha, the fiſſures more diſtant, the intermediate ſpaces ſmoother, and more particularly by the colour of the medullary fibre, which in the poiſonous roots is a deep reddiſh yellow, in the true ipecacuanha, a whitiſh or pale greyiſh.

Ipecacuanha has ſcarcely any ſmell, unleſs during its pulverization or infuſion in liquors, in which circumſtances it emits a faint nauſeous one: in chewing, the wrinkled cortical part proves bitteriſh and ſubacrid, and covers the tongue as it were with a kind of mucilage; the medullary woody fibre is nearly inſipid. Geoffroy obſerves, that in pulverizing conſiderable quantities, the finer powder that flies off, unleſs great care be taken to avoid it, is apt to affect the operator with a difficulty of breathing, a ſpitting of blood, a bleeding at the noſe, or a ſwelling and inflammation of the eyes and face, and ſometimes of the throat; and that theſe ſymptoms go off in a few days, either ſpontaneouſly, or by the aſſiſtance of venæſection.

This root is the mildeſt and ſafeſt emetic that has yet been diſcovered; and may be ventured on almoſt in the loweſt circumſtances, where the ſtomach requires to be unloaded. The common doſe is from ten grains to a ſcruple, and upwards. In the Medical Obſervations and Enquiries, publiſhed by a ſociety of phyſicians in London, a great number of caſes is mentioned, in which two grains operated ſufficiently: in conſtitutions which bore vomiting ill, and which were greatly ruffled by the uſual doſes, two or three grains operated with great eaſe. Where it fails of operating upwards, it commonly purges, and ſometimes conſiderably; in this intention it may be employed, in ſeveral caſes, to advantage, in conjunction with other purgatives, to determine its action downwards: fifteen grains of jalap with two or three of ipecacuanha have been found to purge more than twice the quantity of jalap by itſelf.

The ipecacuanha was firſt introduced, about the middle of the laſt century, as a ſpecific in dyſenteries; and repeated experience has confirmed its efficacy in this diſtemper, not only when uſed as an emetic, but likewiſe when given in ſuch ſmall doſes as ſcarcely to affect the groſſer emunctories. In common dyſenteric fluxes, it frequently performs a cure in a very ſhort ſpace of time; not by its exerting an aſtringent power, as ſome have ſuppoſed, for it does not appear to have any real aſtringency; nor by its mucilaginous ſubſtance covering the inteſtines, and incraſſating thin humours, as others, with more plauſibility, have inferred both from its mucilaginous taſte, and from the ropineſs and ſlimineſs which it manifeſtly communicates to the contents of the ſtomach; but apparently by promoting perſpiration, the freedom of which is in theſe caſes of the utmoſt importance; and an increaſe of which, even in a ſtate of health, is generally obſerved to diminiſh the evacuation by ſtool. In common dyſenteries, the ſkin is for the moſt part dry and tenſe, and perſpiration obſtructed; and indeed this obſtruction, and the converſion of the perſpirable matter upon the inteſtines, is very frequently the immediate cauſe of the diſeaſe. Moſt of the common diaphoretics paſs off, in theſe caſes, without effect: but ipecacuanha, if the patient after a puke or two be covered up warm in bed, brings on a free diaphoreſis, or a plentiful ſweat, by which means the diſtemper has often terminated at once. In putrid or malignant dyſenteries, or where the patient breathes a tainted air, it has not been found equally ſucceſsful: it requires here to be continued for ſeveral days, or repeated as an evacuant, with the further aſſiſtance of rhubarb, cordial antiſeptics, and mild opiates or aſtringents. Where plentiful evacuation is neceſſary, or the offending matter lodged deep, and the operation can be borne without inconvenience, the ipecacuanha is moſt advantageouſly given in ſmall quantities at a time, and repeated at proper intervals, till a vomiting or purging comes on.

The emetic virtue of ipecacuanha reſides in its reſinous parts. By digeſting the root in freſh quantities of rectified ſpirit, and inſpiſſating the filtered tinctures, a reſinous extract is obtained, to the quantity of about three ounces from ſixteen, which, by itſelf, vomits ſtrongly, and with great irritation; the reſiduum yields to water nearly four ounces of a ſoft tenacious mucilage, which has ſcarcely any ſenſible operation. If only a part of the reſin be extracted by ſlight digeſtion in a little highly rectified ſpirit, the remaining root proves more gentle, and rather purgative than emetic: in this ſtate it is recommended by ſome in dyſenteries accompanied with a conſiderable fever, where the root with its natural quantity of reſin might irritate too much; but as ſmall doſes of the root itſelf operate with all the eaſe and gentleneſs that can be wiſhed for, this precarious method of weakening it does not appear adviſeable.

By boiling in water, a part of the reſin is taken up with the mucilage; the extract amounting to about ſix ounces from ſixteen, and proving mildly emetic. The beſt menſtruum for extracting the entire virtue of the root appears to be a mixture of one part of pure ſpirit, with two or rather three parts of water: after ſufficient digeſtion in this menſtruum, neither water nor ſpirit took up any thing conſiderable from the remainder. In the ſhops, wine is employed: an ounce of the root is macerated or digeſted in a pint of canary or mountain; to which ſome add a quarter of an ounce of dried orange peel, to cover the unpleaſant flavour of the ipecacuanha. Theſe tinctures, in doſes of from half an ounce or leſs to an ounce and upwards, prove mildly emetic. *Lewis's Materia Medica.*

IPOMÆA, American jaſmine, in botany, a genus of plants, the corolla of which conſiſts of a ſingle infundibuliform petal; the tube is nearly cylindric, and very long; the limb is patent, and divided into five ſemi-lanceolated plane ſegments; the fruit is a roundiſh capſule, containing three cells; the ſeeds, of which there are ſeveral in each cell, are of an oval figure. This plant is by ſome reckoned a ſpecies of the convolvulus.

IRELAND, an iſland of the Atlantic ocean, ſubject to Great Britain, ſituated between 5° and 10° weſt longit. and between 51° and 56° north latitude; being bounded by the Northern ocean on the north, by St. George's channel, which divides it from Great Britain, on the eaſt, and by the Atlantic and Weſtern ocean on the ſouth and weſt. This country is two hundred and fifty miles long, and one hundred and fifty broad; diſtant from Holyhead, in North Wales, fifty miles, and from Galloway, in Scotland, fifteen miles. It is divided into four large provinces, viz. Ulſter on the north, Leinſter on the eaſt, Munſter on the ſouth, and Connaught on the weſt.

IRIS, the RAINBOW, in phyſiology. See the article RAINBOW.

IRIS, in anatomy, the anterior coloured part of the uvea of the eye. See EYE.

IRIS, in botany, a perennial plant with long narrow leaves, ſtanding edgewiſe to the ſtalk; and large naked flowers, divided deeply into ſix ſegments, of which, alternately, one is erect and another arched downwards, with three ſmaller productions in the middle, incloſing the ſtamina and piſtil: the roots are tuberous, irregular, and full of joints.

IRIS, the flower-de-luce, common iris, or orrice, in botany, a plant with blue flowers, whoſe arched ſegments are bearded with a yellowiſh matter, ſtanding ſeveral on one ſtalk higher than the leaves. It is a native of the mountainous parts of Germany, common in our gardens, and flowers in June.

The roots of this plant have, when freſh, a diſagreeable ſmell, and an acrid nauſeous taſte. They are a ſtrong irritating cathartic; in which intention, their expreſſed juice has been given in hydropic caſes, from one or two drams to three or four ounces, diluted largely with watery or vinous liquors to prevent its inflaming the throat.

The bluiſh expreſſed juice of the flowers changes on being inſpiſſated, eſpecially if a little lime water is added, to a fine green; and in this form is directed, in foreign pharmacopœias, for tinging ſome of the unctuous compoſitions called odoriferous or apoplectic balſams.

IRIS,

IRIS, Florence orrice, ſuppoſed to be only a variety of the foregoing, occaſioned by difference of climate; diſtinguiſhable from it in our gardens, by the flowers being white, and the leaves inclining more to bluiſh. The ſhops are ſupplied from Italy with dried roots ſuperior to thoſe of our own growth, in oblong flattiſh pieces freed from the fibres and browniſh bark, externally of a whitiſh colour, with browniſh ſpecks, internally inclining to yellowiſh, eaſily reducible into farinaceous yellowiſh white powder.

This root, in its recent ſtate, does not ſeem to differ much from the preceding; being, like it, nauſeous, acrimonious, and purgative, though not quite in ſo great a degree, and loſing theſe qualities on being dried. The dry root, as met with in the ſhops, has an unctuous, biterish, pungent taſte, not very ſtrong, but very durable in the mouth: and a light agreeable ſmell, approaching to that of violets. It is uſed in perfumes; in ſternutatory powders, for communicating a grateful flavour, ſomewhat like raſpberries, to wines and to ſpirits; and medicinally in diſorders of the breaſt, for attenuating viſcid phlegm, and promoting expectoration.

IRON, *Mars*, in natural hiſtory, a greyiſh metal, ſoon tarniſhing in the air to a duſky blackiſh hue, and in no long time contracting a yellowiſh or reddiſh ruſt. It is the moſt ſonorous of the metals except copper; the hardeſt and moſt elaſtic of them all; hence its excellence for mechanic inſtruments: it is made into tools, by which all the others are filed, drilled, and cut; and is the only one that ſtrikes ſparks with flint. It ſpreads difficultly under the hammer, but may be extended to a great degree, drawn into wire, as ſlender as the fineſt hairs: it is more eaſily malleable when ignited than when cold; whilſt ſome of the other metals, though ductile when cold, become quite brittle by heat. It is lighter, conſiderably, than copper; and a little heavier than tin. It is the only metallic body which attracts, or is attracted by, the magnet, one of its own ores.

Iron grows red-hot much ſooner than any other metal, and this not only from the application of actual fire, but likewiſe from ſtrong hammering, friction, or other mechanic violence. It nevertheleſs melts the moſt difficultly of all the metals; requiring, in its moſt fuſible ſtate, an intenſe bright white heat. When perfectly malleable, it is not fuſible at all, without additions, or the immediate contact of the burning fuel; and when melted, it loſes that quality, which deprive it at the ſame time of the other, as if fuſibility and malleability were in this metal incompatible.

Solutions of iron made in acids give a yellow ſtain to linen, &c. and ſtrike a black colour with galls and other vegetable aſtringents. Theſe are very valuable properties of iron to the calico-printer, the ſtainer of leather, wood, &c. and the dyer. For linen and leather, the metal is commonly diſſolved in ſour whey or ſmall beer; for dyeing, the vitriol is made uſe of. This metal affords alſo, in its calces, red and yellow pigments to the painter; and a fine blue in the preparation, called from the place where it was firſt diſcovered, Berlin or Pruſſian blue. A ſlight ſolution of vitriol has been employed by ſome as an aſſay liquor for diſtinguiſhing French brandies from common ſpirits prepared in imitation of them; French brandy having uſually an aſtringent impregnation from the oaken caſks in which it has been kept, and hence ſtriking a bluiſh or black colour with the chalybeate ſolution; whilſt ſpirits tinctured only with molaſſes, burnt ſugar, &c. give no ſuch colour. The principle on which the blue colour depends, ſhews that it is no certain teſt: all ſpirits will exhibit it if impregnated with aſtringents; and French brandies will not, without ſuch impregnation.

Iron is exceeding rarely, if ever, found native in the earth. Mr. Lewis ſays he never ſaw a ſpecimen of pure native iron; but the maſſes which have been ſhewn him for ſuch, were either not attracted by the magnet, or not diſſoluble in aqua-fortis. Its ores on the other hand are extremely plentiful in almoſt all parts of Europe: but South America, ſo rich in gold and ſilver, has little of this moſt uſeful metal. The richeſt ores of iron are compact and ponderous, of a browniſh, reddiſh brown, or red colour: they ſcarcely ever participate of perfect ſulphur, the pyritæ excepted, and contain but little foreign matter: ſuch are, the magnet, the hæmatites or blood-ſtone, the common iron-ſtone, and ruddle. The running down of the iron-ſtone requires no particular management, a ſtrong charcoal fire being the principal point.

Smelting of IRON *Ores.*—The ores of iron are commonly calcined previous to the fuſion; the harder ones, though they ſhould contain nothing ſulphureous or arſenical, requiring that proceſs to render them pulverable. In the large works, a quantity of the ore is placed on a bottom of wood or charcoal, intermingled with ſtrata of the ſame kind of fuel; the pile carried up to a conſiderable height, and ſet on fire.

The fuſion is performed in furnaces twenty or thirty feet high, and eight or ten feet wide in the middle, but narrower above and below. The furnace is charged at top with charcoal, and the fire excited by large bellows moved by water. When the whole internal ſurface appears of a ſtrong white heat, the ore is thrown in, by little at a time, with charcoal over it, and commonly a portion of limeſtone, the true uſe of which is probably, not as has been generally ſuppoſed, to abſorb ſulphur, but to promote the fuſion. The ore, gradually melting, drops down through the fuel into the receiver or bottom of the furnace, where a paſſage is open for taking off the ſcum or droſs. The metal, now in ſtrong fuſion, is let out, by a tap-hole, into furrows made in a bed of ſand: the large maſs, which ſets in the main furrow, is called by the workmen a ſow, and the leſſer ones pigs of iron. Chimney-backs, ſtoves, garden-rollers, &c. are formed of this rough metal taken out of the receivers with ladles, and caſt into moulds made of fine ſand. Two or three tons of iron are run off in twenty-four hours: before the force of water was called in aid to work the bellows, ſcarce an hundred weight could be obtained in a day, and a large quantity of the metal was left in the droſs: hence, in ſome places, the ſlags of the old works are now remelted to advantage along with freſh ore. From the richneſs of the ſlags of different ores left by former times, ſome have been miſled into an opinion, that the metal was regenerated in them.

From the great conſumption of wood in this buſineſs, and its ſcarcity in ſome places where there are rich mines of iron, attempts have been made to ſubſtitute other fuels. Peat has been found to anſwer tolerably well: in ſome parts of England, a quantity of this has for a conſiderable time been mixed with the charcoal; and a patent has been lately obtained for running down the ore with peat alone. Pit-coal renders the iron hard and brittle: this inconvenience is ſaid to be in a good meaſure prevented, by previouſly coaking the coal, as is cuſtomary to fit it for the drying of malt.

The impure iron, as run from the ore, is melted down in another furnace, intermixed with charcoal; a ſtrong blaſt of air being impelled on the ſurface of the metal, by which its fuſion is remarkably promoted. On diſcontinuing the action of the bellows, the iron thickens into a maſs called a loop, which is conveyed under a large hammer raiſed by the motion of a water-mill. The iron, beat into a thick ſquare, is heated till ready to melt, and forged again: by a few repetitions of this proceſs, it becomes completely malleable, and is at length formed into bars for ſale. A large quantity of vitreous ſcoria ſeparates both in the fuſion and the forging: the rough caſt iron, obtained from ſome ores, loſes more than half its weight in being made into bars.

Preparation of IRON, in medicine, are, 1. The crude filings, reduced to an impalpable powder, greatly recommended in female diſorders.

2. The crocus martis. See CROCUS.

3. The flores martiales, or flowers of iron, See the article FLOS.

4. The ſal martis, or ſalt of iron, which is prepared thus: mix together a quart of water, and eight ounces of the oil of vitriol; pour the oil of vitriol in by a little at a time: put the mixed liquor into a glaſs-veſſel, and add to it four ounces of the filings of iron: when the ebullition is over, evaporate the liquor to a pellicle, and ſet it to ſhoot, there will then be a green vitriol or ſalt found in fair cryſtals; dry them for uſe.

This ſalt is one of the moſt powerful preparations of this metal; it opens obſtructions of all kinds, ſtrengthens the viſcera, is an excellent medicine in cachexies, and deſtroys worms.

5. Tincture of iron, with ſpirit of ſalt, is made thus: take filings of iron, half a pound; Glauber's ſpirit of ſea ſalt, three pounds; rectified ſpirit of wine three pints: digeſt the ſpirit of ſalt and the filings together, without heat, as long as the ſpirit will work upon them; then after the fæces have ſubſided, pour off the clear liquor, evaporate it to one pound, and to this add the ſpirit of wine.

This has the ſame virtues as the crocus martis. See the article CROCUS.

6. Chalybeate, or ſteel-wine, is made in the following manner: take filings of iron, four ounces; cinnamon and mace, of each half an ounce; of rheniſh wine, two quarts; infuſe them a month, without heat, often ſhaking the veſſel, and then filter it off for uſe.

This wine is an excellent ſtomachic and aperient; a moderate glaſs may be drank once or twice a day, or it may be mixed in apozems of the aperient vegetables.

IRONY, in rhetoric, is when a perſon ſpeaks contrary to his thoughts, in order to add force to his diſcourſe; whence Quintilian calls it *diverſiloquium*.

Thus, when a notorious villain is ſcornfully complimented with the titles of a very honeſt and excellent perſon; the character of the perſon commended, the air of contempt that appears in the ſpeaker, and the exorbitancy of the commendations, ſufficiently diſcover the diſſimulation or irony.

IRRADIATION, the act of emitting ſubtile effluvia, like the rays of the ſun every way.

IRRATIONAL, an appellation given to ſurd numbers and quantities. See the article NUMBER, QUANTITY, and SURD.

IRREGULAR, ſomething that deviates from the common forms, or rules; thus we ſay an irregular fortification, an irregular figure, &c. See the article FORTIFICATION, &c.

IRREGULAR, in grammar, ſuch inflections of words as vary from the general rules; thus we ſay, irregular nouns, irregular verbs, &c.

IRREGULAR BODIES are ſolids not terminated by equal and ſimilar ſurfaces.

IRREGULAR COLUMN, in architecture, a column which does not only deviate from the proportions of any of the five orders, but whoſe ornaments, whether in the ſhaft or capital, are abſurd and ill choſen.

ISAIAH, or *Prophecy of* ISAIAH, a canonical book of the Old Teſtament. Iſaiah is the firſt of the four greater prophets, the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood, his father Amos being brother to Azariah, king of Judah. The five firſt chapters of this prophecy relate to the reign of Uzziah; the viſion, in the ſixth chapter, happened in the time of Jotham: the next chapters to the fifteenth, include his prophecies under the reign of Ahaz; and thoſe that were made under the reigns of Hezekiah and Manaſſeh, are related in the next chapters to the end. The ſtile of this prophet is noble, ſublime, and florid. Grotius calls him the Demoſthenes of the Hebrews. He had the advantage, above the other prophets, of improving his diction by converſing with men of the greateſt parts and elocution, and this added a ſublimity, force, and majeſty to what he ſaid. He impartially reproved the vices of the age in which he lived, and openly diſplayed the judgments of God that were hanging over the Jewiſh nation; at the ſame time denouncing vengeance on the Aſſyrians, Egyptians, Ethiopians, Moabites, Edomites, Syrians, and Arabians, who were inſtrumental in inflicting thoſe judgments. He foretold the deliverance of the Jews from their captivity in Babylon, by the hand of Cyrus king of Perſia, an hundred years before it came to paſs; but the moſt remarkable of his predictions are thoſe concerning the Meſſiah, in which he not only foretold his coming in the fleſh, but all the great and memorable circumſtances of his life and death.

ISATIS, Woad. See the article WOAD.

ISCHIADIC, in anatomy, a name given to two crural veins, called the greater and leſſer iſchias. See the article VEIN.

ISCHIUM, in anatomy, the name of a bone deſcribed under the article innominata oſſa. See the article INNOMINATA.

ISCHURY, *Iſchuria*, in phyſic, a ſuppreſſion of urine.

The word is Greek, ἰσχυρία, and formed from ἰσχω, to retain, and ὑρον, urine.

Women with child are often troubled with an entire ſuppreſſion of urine; the moſt general cauſes of which are gravel and ſtone, an inflammation of the neck of the bladder, owing to the piles; or a ſtrangulation of the neck of the bladder betwixt the os pubis and head of the child, when it is ſunk down very low.

In the two firſt caſes, general remedies, as bleeding, emollient clyſters, and gentle purges with ſoftening decoctions, are of great uſe; but nothing gives ſo ſpeedy a relief as a catheter. But when the head of the child is ſunk very low, and preſſes ſtrongly againſt the os pubis, the catheter will not paſs; and then the remedy is to put back the child's head, which immediately gives liberty to the urine to come away without uſing the catheter.

La Motte makes a diſtinction betwixt a ſuppreſſion and retention of urine. In the latter caſe the patient has frequent motions to make water, without being able to do it. But in a total ſuppreſſion of urine the patient has ſeldom or never any inclination to make water, and if any happen, it is done in a moment: this laſt is the moſt dangerous.

To diſcharge the urine by a puncture of the bladder is never undertaken, when relief can be had from internal medicines, or the introduction of the catheter. Now the catheter cannot be introduced in the following caſes: 1. When the neck of the bladder is greatly inflamed, whereby the urethra is contracted. 2. A caruncle, cicatrix, or hard tubercle may obſtruct the paſſage. 3. The introduction of the catheter in old men is ſometimes impracticable from the ſtricture or wrinkles of the urethra. 4. From the diſtention of its ſpongy ſubſtance with blood. 5. From a ſcirrhoſity or preternatural tumor of the proſtate gland. Laſtly, from a ſtone lodged in the neck of the bladder. Upon ſuch occaſions recourſe muſt be had to this operation; and among the various methods made uſe of, Heiſter prefers the following, namely, to make an inciſion on the left ſide of the future of the peritonæum into the body of the bladder, ſo as not to injure its neck, with a trochar and cannula. After which the perforator is extracted, but the cannula remains there for the more ready diſcharge of the urine, by which means both the operation and cure are greatly facilitated. Nor is it improper to paſs one or two fingers into the anus for the better direction of the inſtrument into the bladder, and the preſervation of the rectum.

When the cauſe is removed, the tube may be extracted, and the wound healed by the application of balſam of capivi.

ISIA, feaſts and ſacrifices anciently ſolemnized in honour of the goddeſs Iſis.

ISINGLASS, *Ichthyocolla*, in the materia medica, &c. See ICHTHYOCOLLA.

ISLAND, a tract of dry land, encompaſſed with water, in which ſenſe it ſtands contradiſtinguiſhed from continent, or terra firma.

ISLE, in general, denotes the ſame with iſland, only frequently uſed in a diminutive ſenſe.

ISLES, in architecture, denote the ſides or wings of a building.

ISOCHRONAL, ISOCHRONE, or ISOCHRONOUS, is applied to ſuch vibrations of a pendulum, as are performed in the ſame ſpace of time, as all the vibrations or ſwings of the ſame pendulum are, whether the arches it deſcribes be longer or ſhorter: for when it deſcribes a ſhorter arch, it moves ſo much the ſlower, and when a long one proportionably faſter.

ISOCHRONAL LINE, that in which a heavy body is ſuppoſed to deſcend without any acceleration. See the article ACCELERATION.

ISOPERIMETICAL FIGURES. See MAXIMUM and MINIMUM.

ISOSCELES, TRIANGLE, in geometry, a triangle which hath two equal ſides, as A B C (plate LXXVII. *fig.* 1.) where the ſide A B is equal to A C.

ISPIDA, the king fiſher, in ornithology, a genus of the picæ-order of birds, with a bill of a trigonal figure, ſomewhat arcuated, compreſſed, and its two chaps equal: there are four toes on each foot, with only one of them placed behind.

This is a very numerous genus, the ſpecies of which are chiefly diſtinguiſhed by their ſize and different colours.

ISSUE, in law, has ſeveral ſignifications, it being ſometimes taken for the children begotten between a man and his wife; ſometimes, for profits ariſing from amercements and fines; and ſometimes, for the profits iſſuing out of lands or tenements: but this word generally implies the concluſion, or point of matter, that iſſues from the allegations and pleas of the plaintiff and defendant in a cauſe tried by a jury of twelve men.

ISSUES, in ſurgery, ſmall artificial apertures made in a fleſhy part of the body, to drain off ſuperfluous or noxious humours.

An iſſue ſhould be made in the middle of a muſcle, that the neceſſary motion of the part may not incommode or put the patient to pain. The beſt way of making iſſues in children is by applying a ſmall piece of bliſtering plaſter, as big as a pea, to the part; and letting it lie on for a few hours, it will cauſe a bliſter: upon raiſing the ſkin, apply a pea and compreſs it tight with a bandage, till by degrees it ſinks in and forms an iſſue.

ISTHMIA, or ISTHMIAN GAMES, ἰσθμια, one of the four ſolemn games which were celebrated every fifth year in Greece; ſo called from the Corinthian iſthmus, where they were kept.

Theſe games, according to ſome, were inſtituted in honour of Palæmon, or Melicertes, the ſon of Athamas king of Thebes, and Ino. Others report, that they were inſtituted by Theſeus, in honour of Neptune: others again are of opinion, that there were two diſtinct ſolemnities obſerved in the Iſthmus, one to Melicertes, and another to Neptune. Theſe games were held ſo ſacred and inviolable, that when they had been intermitted for ſome time, through the oppreſſion and tyranny of Cypſelus, king of Corinth, after the tyrant's death the Corinthians, to renew the memory of them, employed their utmoſt power and induſtry. The victors were rewarded with garlands of pine-leaves; afterwards parſley was given them; but at length, the pine was reſumed, and to this was added the reward of one hundred ſilver drachmæ. Theſe games were ſo celebrated, and the concourſe at them ſo great, that only the principals of the moſt remarkable cities could have place in them. The Athenians had only as much room allowed them as the ſail of a ſhip, which they ſent yearly to Delos, could cover.

ISTHMUS, in geography, a narrow neck of land that joins two continents, or joins a peninſula to the terra firma, and ſeparates two ſeas. The moſt celebrated iſthmuſes are thoſe of Panama, or Darien, which joins North and South America; and that of Suez, which connects Aſia and Africa; that of Corinth, of Crim Tartary, &c.

ITALIAN, the language ſpoken in Italy.

This tongue is derived principally from the Latin; and of all the languages formed from the Latin, there is none which carries with it more viſible marks of its original than the Italian. It is accounted one of the moſt perfect among the modern tongues, containing words and phraſes to repreſent all ideas, to expreſs all ſentiments, to deliver one's ſelf on all ſubjects, to name all the inſtruments and parts of arts, &c. It is however complained, that it has too many diminutives and ſuperlatives, or rather augmentatives, but without any great reaſon: for if theſe words convey nothing farther to the mind than the juſt ideas of things, they are no more faulty than our pleonaſms and hyperboles. The language correſponds to the genius of the people; they are ſlow and thoughtful, and accordingly their language runs heavily, though ſmoothly, and many of their words are lengthened out to a great degree. They have a great taſte for muſic, and to gratify their paſſion this way, have altered abundance of their primitive words, leaving out conſonants, taking in vowels, ſoftening and lengthening out their terminations for the ſake of the cadence. Hence the language is extremely muſical, and ſucceeds better than any other in operas, and ſome parts of poetry; but it fails in ſtrength and nerves: hence alſo, a great part of its words borrowed from the Latin, become ſo far diſguiſed, that they are not eaſily known again.

ITALIC CHARACTERS, in printing. See the article LETTER.

ITALIC or ITALIAN HOURS, the twenty-fours of the natural day, accounted from the ſun-ſetting of one day, to the ſame again the next day. See HOUR.

ITALIC SECT, a party of ancient philoſophers, founded by Pythagoras, ſo called, becauſe that philoſopher taught in Tarentum, Metapontus, Heraclea, Naples, &c. in Italy.

ITALY, a country, ſituated between ſeven and nineteen degrees eaſt long. and between thirty-eight and forty-ſeven degrees north latitude, bounded by Switzerland, and the Alps, which ſeparate it from Germany, on the north; by the gulph of Venice, on the eaſt; by the Mediterranean ſea, on the ſouth; and by the ſame ſea and the Alps, which ſeparate it from France, on the weſt; and if we include Savoy, which lies indeed on the weſt-ſide of the Alps, between Italy and France, we muſt extend it a degree farther weſt: this is uſually deſcribed however with Italy, as it is contiguous to Piedmont, and has the ſame ſovereign, being a province of the king of Sardinia's dominions. Italy is ſaid to reſemble a boot, and is in length from north-weſt to ſouth-eaſt 600 miles; the breadth is very unequal; in the north, which may be called the top of the boot, it is 400 miles broad from eaſt to weſt; in the calf of the leg, or middle, it is about 120 miles broad; and towards the ſouth, about the inſtep, eighty miles broad; and comprehends the following countries or ſubdiviſions. 1. In the north are the duchies of Savoy, Piedmont, and Montſerrat; the territories of Genoa; the duchies of Milan, Mantua, Parma, Modena, and the territories of Venice. 2. In the middle of Italy, are the duchy of Tuſcan, the pope's dominions, and the ſtate of Lucca. 3. And in the ſouth is the kingdom of Naples.

ITCH, a diſeaſe of the ſkin which is corrupted by the oozing out of certain ſharp humours, which gather into puſtules, and occaſion a prurigo or itching.

The itch is either moiſt or dry, which, appearing in the joints principally at firſt, gradually ſpreads through the reſt of the body, except the head.

This diſeaſe firſt appears in a reddiſh roughneſs of the ſkin; which is ſucceeded by pimples, that let out matter or a ſharp ichor; and the exulceration is attended with itching, and ſpreads by contagion. It may juſtly be called an animated diſeaſe, as owing its origin to ſmall animals. For there are certain inſects, ſo very ſmall as hardly to be ſeen, without the aſſiſtance of a microſcope, which depoſit their eggs in the furrows of the cuticle, as in proper neſts; where, by the warmth of the place, they are hatched in a ſhort time, and the young ones coming to full growth penetrate into the very cutis with their ſharp heads, and gnaw and tear the fibres. Their bitings cauſe an intolerable itching, which brings on a neceſſity of ſcratching; whereby the part is torn, and emits a thin humour, which concretes into hard ſcabs; whilſt the little worms conſtantly burrowing under the cuticle, and laying their eggs in different places, ſpread the diſeaſe.

Hence the reaſon manifeſtly appears why the diſeaſe is communicated by the linen, wearing apparel, gloves, &c. which were uſed by infected perſons: for the eggs which had ſtuck to ſoft ſubſtances of this kind, are rubbed into the furrows of the cuticle, and are there hatched and nouriſhed.

Now what is of greateſt moment in this theory is, that the knowledge of the true cauſe of the diſeaſe naturally points out the cure: for neither cathartics nor ſweeteners of the blood are of any ſervice here; the whole management conſiſts in external applications, in order to deſtroy theſe corroding worms, and this is eaſily effected: wherefore,

fore, firſt let the patient go into a warm bath, and then let the parts affected be anointed every day, either with the ointment of ſulphur, or the ointment with precipitate of mercury, which is leſs offenſive to the olfactory organs; inſtead of which a liniment may be made of orange flowers, or red roſes, the mercurial red corroſive, and hogs-lard, pounded together, which is of a very pleaſant ſmell, and of equal efficacy. *Mead.*

ITINERANT JUDGES, a name formerly given to thoſe judges who were ſent into ſeveral counties to hear cauſes.

JUBILEE, among the Jews, denoted every fiftieth year, being that which followed the revolution of ſeven weeks of years; at which time all ſlaves were made free, all debts annihilated, and all lands, &c. reverted to their ancient poſſeſſors; all agriculture was forbid, and the poor intitled to all the productions of the earth that year. The privilege extended only to original Iſraelites.

According to Maſius, the word is derived from Jubal, the inventor of muſical inſtruments; whence the words Jobel, and Jubilee, ſignified the year of deliverance and remiſſion, becauſe proclaimed with the ſound of one of thoſe inſtruments, which at firſt was no more than the horn of a ram.

The Chriſtians, in imitation of the Jews, have likewiſe eſtabliſhed jubilees, which began in the time of pope Boniface VIII. in the year 1300, and are now practiſed every twenty-five years; but theſe relate only to the pretended forgiveneſs of ſins, and the indulgences granted by the church of Rome: together with the privilege of performing a thouſand frolics in maſquerade. The ceremony of the jubilee obſerved at Rome, begins in the following manner: the pope goes to St. Peter's church, to open the holy gate, which is walled up, and opened only on this occaſion; and, holding a golden hammer in his hand, he knocks at the gate three times, repeating theſe words, *aperite mihi portas juſtitiæ*, &c. *Open to me the gates of righteouſneſs; I will go into them, and I will praiſe the Lord*, Pſal. cxviii. 19. upon which the maſons fall to work, and break down the wall that ſtops up the gate: which done, the pope kneels down before it, and the penitentiaries ſprinkle him with holy water. Then, taking up the croſs, he begins to ſing te deum, and enters the church, followed by the clergy. In the mean time, three cardinal-legates are ſent to open the three other holy gates which are in the churches of St. John of Lateran, St. Paul, and St. Mary the Greater. When the holy year is expired, the holy gates are ſhut in this manner: the pope, after he has bleſſed the ſtones and mortar, lays the firſt ſtone, and leaves there twelve boxes of gold and ſilver medals; after which the holy gates are walled up as before, and continue ſo till the next jubilee.

JUDAISM, the religious doctrines and rites of the Jews. See JEWS.

JUDE, *or the general Epiſtle of* JUDE, a canonical book of the New Teſtament, written againſt the heretics, who by their diſorderly lives and impious doctrines, corrupted the faith and good morals of the Chriſtians. St. Jude draws them in lively colours, as men given up to their paſſions, full of vanity, conducting themſelves by worldly wiſdom, and not by the ſpirit of God.

In the early ages of Chriſtianity, ſeveral rejected this Epiſtle becauſe the apocryphal books of Enoch and the aſcenſion of Moſes are quoted in it. Nevertheleſs, it is to be found in all the ancient catalogues of the ſacred writings; and Clement of Alexandria, Tertullian and Origen, quote it as written by Jude, and reckon it among the books of ſacred Scripture.

St. JUDE'S DAY, the ſame with that of St. Simon. See the article SIMON.

JUDGE, an officer appointed by the ſovereign powers of any country to diſtribute juſtice to their ſubjects which they themſelves cannot do in perſon.

Book of JUDGES, a canonical book of the Old Teſtament, ſo called from its relating the ſtate of the Iſraelites under the adminiſtration of many illuſtrious perſons who were called judges, from their being both the civil and military governors of the people, and who were raiſed up by God upon ſpecial occaſions, after the death of Joſhua, till the time of their making a king. In the time of this peculiar polity, there were ſeveral remarkable occurrences, which are recorded in this book. It acquaints us with the groſs impiety of a new generation which ſprung up after the death of Joſhua, and gives us a ſhort view of the diſpenſations of heaven towards this people, ſometimes relieving and delivering them, and at others, ſeverely chaſtiſing them by the hands of their enemies.

The book of Judges is uſually divided into two parts; the one containing the hiſtory of the judges from Othniel to Sampſon; which ends with the ſixteenth chapter: the other containing ſeveral memorable actions, which were performed in or about the time of the judges, from the ſeventeenth chapter to the end of the book. The author of this book is wholly unknown; ſome aſcribe it to Samuel, others to Hezekiah, and others to Ezra.

JUDGMENT, among logicians, a faculty or rather act of the human ſoul, whereby it compares its ideas, and perceives their agreement or diſagreement. See the article KNOWLEDGE.

JUDGMENT, in law, the ſentence of the judges upon a ſuit, &c.

JUDGMENTS *for crimes*, in caſe of treaſon or felony, muſt be by an expreſs ſentence, an out-lawry, or abjuration: and no judgment can be inflicted contrary to law, or that is not appointed by act of parliament.

JUDGMENTS *for debts*, are acknowledged by a perſon's giving a general warrant of attorney to any attorney of the court in which it is to be acknowledged, to appear for him at the ſuit of the party to whom the ſame is to be done, and to file common bail, receive a declaration, and then to plead, *non ſum informatus*, I am not informed; or to let it paſs *nihil dicit*, he ſays nothing; upon which judgment is entered for want of a plea.

JUGALE, in anatomy the cheek bone. See the article MALA.

JUGERUM, in Roman antiquity, a ſquare of one hundred and twenty Roman feet; its proportion to the Engliſh acre being as ten thouſand to ſixteen thouſand and ninety-ſeven. See MEASURE.

JUGULAR, in anatomy, an appellation given to two veins of the neck, which ariſe from the ſubclavians. 1. The external jugular, diſtributed over the external parts of the head; and which, in its ſeveral parts, receives different denominations from them, as the frontal, temporal, occipital, &c. vein. 2. The internal jugular, which gives ramifications to the larynx, the pharynx, the muſcles of the os hyoides, and to the tongue; thoſe which are under its vertex being called raninæ. But beſides theſe branches, its trunk terminates in a diverticulum, called the jugular ſack, and brings back the blood from the ſinuſes of the dura mater, and from the brain. See the article VEIN.

There are alſo certain glands in the anterior part of the neck, called jugular. See GLAND.

JUICE denotes the ſap of vegetables when expreſſed. See SAP.

JUICE is alſo uſed to denote the liquors of animals, as the nervous juice, the pancreatic juice, &c.

JUJUBES, *Jujubæ*, in pharmacy, a fruit of the plum kind, about the ſize and ſhape of an olive, conſiſting of a pretty thick reddiſh yellow ſkin, a whitiſh fungous pulp, and a wrinkled ſtone of an oblong figure. It is the produce of a prickly tree, with three-ribbed leaves, and herbaceous or yellowiſh flowers, ſometimes found wild, and commonly cultivated in the ſouthern parts of Europe.

This fruit has an agreeable ſweet taſte; and in thoſe countries where it is common, makes an article of food in its recent ſtate, and of medicine when half dried; decoctions of it being uſed, like other glutinous ſweets, as incraſſants, and demulcents in defluxions on the breaſt.

The jujubes have been made a general ingredient in pectoral decoctions; but they are now become a ſtranger to the ſhops, the tree not producing fruit in this climate; and that which we received from abroad being commonly mouldy or carious.

JULEP, in pharmacy, an alterative medicine, unknown to the ancient Greeks, and invented by the Arabians, compoſed chiefly of diſtilled waters, &c. and ſweetened with ſugar or proper ſyrups.

It was ſo called becauſe uſually prepared of ſweet ingredients, julep ſignifying, in the Perſian language, a ſweet potion.

JULIAN PERIOD, in chronology, a period ſo called as being adapted to the Julian year.

It is made to commence before the creation of the world. Its principal advantage lies here, that the ſame years of the cycles of the ſun, moon, and indiction, of which three cycles it was made to conſiſt by Joſeph Scaliger in 1580, belonging to any year of this period, will never fall together again till after the expiration of ſeven thouſand nine hundred and eighty years. There is taken for the firſt year of this period, that which hath the firſt of the cycle of the ſun, the firſt of the cycle of the moon, and the firſt of the indiction cycle, and ſo reckoning on.

The firſt year of the Chriſtian æra is always, in our ſyſtems of chronology, the 4714th of the Julian period.

To find what year of the Julian period any given year of Chriſt anſwers to: to the given year of Chriſt add 4713, becauſe ſo many years of the Julian period were expired A. D. 1; and the ſum gives the year of the Julian period ſought.

On the contrary, having the year of the Julian period given, to find what year of Chriſt anſwers thereto: from the year of the Julian period given ſubſtract 4713, and the remainder will be the year ſought.

JULUS, in botany, the ſame with what is otherwiſe called catkins or amentaceous flowers.

JULUS is alſo the name of an inſect very common among rubbiſh, and called in Engliſh the gally-worm: it is furniſhed with a great number of feet, has the power of rolling itſelf up like a ball when touched, and is eſteemed a very valuable medicine in the jaundice and ſuppreſſion of urine.

JULY, the ſeventh month of the year, during which the ſun enters Leo.

It was called Julius, by Marc Anthony, from the ſurname of the dictator C. Cæſar, who was born in this month. It was before called Quintilis, as being the fifth month of the year in Romulus's calendar, which began in March.

JUMENTA, in zoology, the name by which Linnæus calls the fifth order of quadrupeds, the characteriſtic of which is, that the teeth of all the animals belonging to it are placed in a different manner from the other five orders. See the article QUADRUPED.

To this order belong the elephant, rhinoceros, hippopotamus, horſe, and hog. See ELEPHANT, RHINOCEROS, &c.

JUNCUS, the ruſh, in botany, a genus of plants which has no corolla; but the perianthium, when freſh and coloured, greatly imitates one: the fruit is a coloured capſule, of a triquetrous figure, and formed of three valves, containing a few roundiſh ſeeds.

Authors have divided the ſeveral ſpecies of juncus into what they call ruſhes, and ruſh-graſſes, from their having or wanting leaves; but the fructifications in both are the ſame.

JUNCUS ODORATUS, a name ſometimes given to ſchoenanth. See SCHOENANTH.

JUNIPER, in botany, an ever-green tree or buſh, clothed with ſlender, narrow, ſtiff, ſharp leaves, like prickles, which ſtand generally three together: the flowers are a kind of ſmall ſcaly catkins, growing on one plant; the fruit, round berries, growing on a different one, containing each three oblong irregular ſeeds. It is common on heaths in different parts of Europe; and is found, at all ſeaſons of the year, both with unripe green or red berries, and with ripe bluiſh black ones.

The berries are brought chiefly from Holland and Italy: they ſhould be choſen freſh, not much ſhrivelled, and free from mouldineſs, which they are very ſubject to contract in keeping. They have a moderately ſtrong, not diſagreeable, ſmell, and a warm pungent ſweetiſh taſte, which, if they are long chewed or previouſly well bruiſed, is followed by a conſiderable bitterneſs. Diſtilled with water, they yield a yellowiſh eſſential oil, very ſubtile and pungent, in ſmell greatly reſembling the berries; in quantity, if they have been ſufficiently bruiſed, about one ounce from forty: the remaining decoction, inſpiſſated to the conſiſtence of a rob or extract, has a pleaſant, balſamic, ſweet taſte, with a greater or leſs degree of bitterneſs. A part of the flavour of the berries ariſes alſo in diſtillation with rectified ſpirit: the inſpiſſated tincture conſiſts of two diſtinct ſubſtances; one oily and ſweet; the other tenacious, reſinous, and aromatic.

Theſe berries are uſeful carminatives, detergents, and diuretics. The diſtilled oil is a very ſtimulating diuretic, approaching in quality to that of turpentine, like which, it impregnates the urine with a violet ſmell: the ſpirituous extract gives the ſame kind of ſmell; as does likewiſe the berry in ſubſtance, in a lower degree; but the watery extract or rob, as being diveſted of the oil, has no ſuch effect. This laſt may be uſed with advantage in caſes where the more ſtimulating preparations would be improper; as in catarrhs, debilities of the ſtomach and inteſtines, and difficulties of the urinary excretions, in perſons of an advanced age. Among the aromatics that have been tried in conjunction with juniper berries, ſweet fennel ſeeds and carraway ſeeds ſeem the beſt adapted to improve their flavour: a cordial water is prepared in the ſhops by drawing off a gallon of proof ſpirit from a pound of the berries, and an ounce and a half of each of the ſeeds. The water is ſtrongly impregnated with the volatile virtue of the berry; to which the more fixed ones may in many caſes be uſefully ſuperadded, by mixing with it a proper quantity of rob.

We uſed to keep a diſtilled ſpirituous water of juniper in the ſhops; but the vulgar got an opinion of its being a pleaſant dram, and conſequently the making it became the buſineſs, not of the apothecary, but the diſtiller, who ſold it under the name of geneva; but at preſent it is only a better kind that is made with the juniper-berry; what they commonly ſell is made with no better ingredient than oil of turpentine, put into the ſtill with a little common ſalt, and with the coarſeſt ſpirit they have, which is drawn off much below proof ſtrength, and is conſequently a liquor that one would wonder any people could accuſtom themſelves to drink for pleaſure.

JUNK, among ſailors, certain pieces of old cable cut into different lengths.

JUNO, in aſtronomy, the name by which ſome call the ſecond of Jupiter's ſatellites. See the article JUPITER.

JUNTA, JUNTO, or JUNCTO, in matters of government, denotes a ſelect council for taking cognizance of affairs of great conſequence, which require ſecrecy.

IVORY, *Ebur*, the tuſk, or dens exertus of an elephant, growing on each ſide of his trunk, in form of a horn. Each tuſk is ſix or ſeven feet in length, and as thick as a man's thigh at the baſe, and almoſt ſolid; and both together ſometimes weigh about three hundred and thirty pounds.

It is much eſteemed for its colour, poliſh, and the fineneſs of its grain when wrought.

The ivory of the iſles of Ceylon and Achem never becomes yellow, as that of the terra firma and the Eaſt-Indies does; on which account the former is dearer.

We have alſo fine ivory brought from Angola, Sumatra, &c. Large quantities of it are not taken in the Eaſt-Indies immediately from the head of the animal, but found buried in the earth.

The preparations of ivory have all the ſame virtues with thoſe of harts-horn, and its raſpings, in the ſame manner as ſhavings of harts-horn boiled into a jelly with water, and have the ſame reſtorative qualities.

Staining and marbling of IVORY *yellow.* —Boil it firſt in a ſolution of alum, in the proportion of one pound to two quarts of water: and then prepare a tincture of the French berries, by boiling half a pound of the berries, pounded, in a gallon of water with a quarter of a pound of pearl aſhes. After this tincture has boiled about an hour, put the ivory, previouſly boiled in the alum water into it; and let it remain there half an hour.

If turmeric root be uſed inſtead of the French berries, a brighter yellow may be obtained; but the ivory muſt in that caſe be again dipped in alum water after it is taken out of the tincture; otherwiſe an orange-colour, not a yellow, will be produced from the effect of the pearl-aſhes on the tumeric.

Staining IVORY *green.* —It muſt be boiled in a ſolution of

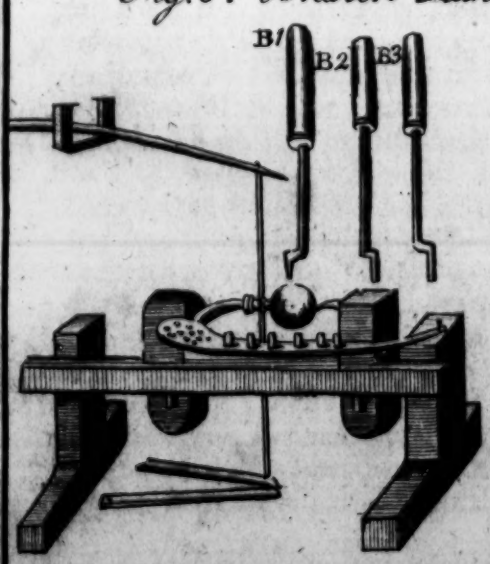

Fig. 9. An Iron Lathe for turning small Work in Metal.

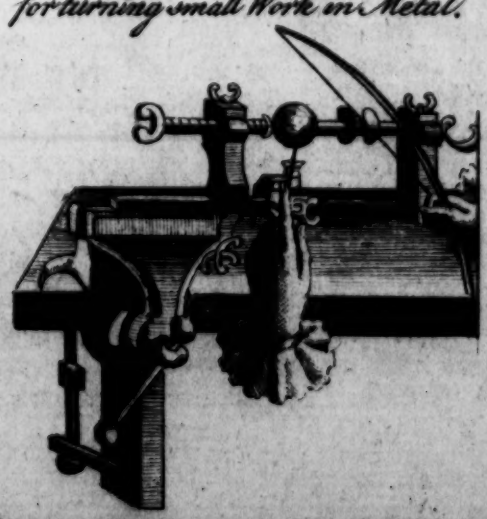

of verdigriſe in vinegar; or of copper in aqua-fortis, prepared as above directed, a veſſel of glaſs or earthen ware being employed for this purpoſe, till it be of the colour deſired.

Staining IVORY *red.* — Take ſtrong lime-water, prepared as for other purpoſes; and the raſpings of Braſil-wood, in the proportion of half a pound to a gallon. Let them boil for an hour; and then put in the ivory, prepared by boiling in alum-water in the manner beforementioned for the yellow; and continue it there till it be ſufficiently coloured. If it be too crimſon, or verge toward the purple, it may be rendered more ſcarlet, by dipping again in the alum-water.

Staining IVORY *blue.* — Stain the ivory firſt green, according to the manner above deſcribed; and then dip it in a ſolution of pearl-aſhes, made ſtrong and boiling hot: but it muſt not be continued longer, nor dipped oftner, than is neceſſary to convert the green to blue.

The ivory may otherwiſe be boiled in the tincture of indigo, prepared as by the dyers; and afterwards in the ſolution of tartar.

Staining IVORY *purple.* — This colour is to be treated in the ſame manner as was directed for the red, except that log-wood muſt be ſubſtituted in the place of Braſil-wood; and the uſe of the alum-water muſt be omitted wholly.

If a redder purple be wanted, a mixture of the log-wood and Braſil muſt be employed, inſtead of the log-wood alone. The proportion may be equal parts; or any leſs proportion of the Brazil, according to the colour deſired.

By this method you may alſo imitate tortoiſe-ſhell and ſeveral other ſubſtances in ivory.

JUPITER, ♃, in aſtronomy, one of the ſuperior planets, remarkable for his brightneſs.

This planet is ſituated between Saturn and Mars, and revolves about his own axis in 9 hours 56 minutes. His periodical revolution round the ſun is performed in 4332 days, 12 hours, 20 minutes, or almoſt 12 years, in an orbit whoſe radius or ſemi-diameter is equal to 424 millions of miles. The inclination of the orbit to the plane of the ecliptic is 1°. 20′. The place of the node ☋ 7° 39′ 54″; and of the aphelion ♎ 9° 9′ 54″.

Jupiter is the largeſt of all the planets, his diameter being 81155 Engliſh miles. See PLANET.

Jupiter has had his ſpots obſervable, ever ſince the invention and uſe of large teleſcopes; and from repeated obſervations they ſhew Jupiter's revolution about his axis is in 9 hours and 56 minutes. Beſides theſe ſpots, Jupiter has the appearance of three zones or belts encompaſſing his body. (See plate LXXVII. *fig.* 2.) Sometimes more, ſo that his diſk ſeems clouded with them: what they are, no body yet can tell. The axis of this planet is alſo nearly perpendicular to the plane of his orbit.

Conſidering the large magnitude of Jupiter, and his ſhort diurnal rotation, the equatorial parts of his ſurface muſt have a prodigious velocity, which of conſequence muſt cauſe him to be of a ſpheroidical figure (as was ſhewn of the earth.) Accordingly Caſſini found the axis of the equator to be to that of the poles as 14 to 15; but Mr. Pound afterwards more exactly determined them to be as 12 to 13, agreeable to Sir Iſaac Newton's computation.

Jupiter is obſerved with a teleſcope to have four ſatellites, which move about him in the times and diſtances following, viz. The firſt in 1 day, 18 hours, 27 minutes, at the diſtance of 5.6 ſemi-diameters of Jupiter's body from his center, as meaſured by a micrometer. The ſecond in 3 days, 13 hours, 13 minutes, at the diſtance of 9 ſemi-diameters. The third in 7 days, 3 hours, 42 minutes, at the diſtance of 14.3 ſemi-diameters. The fourth in 16 days, 16 hours, 32 minutes, at the diſtance of 25.3 ſemi-diameters.

Galileo firſt diſcovered the ſatellites or moons of Jupiter, in the year 1610; and called them Medicea ſidera, or Medicean ſtars, in honour of the family of the Medici, his patrons. The famous piece called Sidereus Nuncius, in which he particularly deſcribes the diſcovery of theſe ſtars, he dedicated to Coſmus Medicis II. the fourth great duke of Hetruria.

The orbits of Jupiter's moons lie nearly in the plane of the ecliptic, which is the reaſon why their motion is apparently in a right line, and not circular, as it really is. To underſtand this, let S (plate LXXVII. *fig.* 3.) be the ſun, T the earth in its orbit T H, I the planet Jupiter in his orbit A I B, and in the center of the 4 orbits of his moons. Then, becauſe the plane of thoſe orbits does nearly paſs through the eye, the real motion of the ſatellite in the periphery will be apparently in the diameter of the orbit, which is at right angles to the line joining the center of the earth and Jupiter.

Thus ſuppoſing the earth at R, if D C be drawn through the center of Jupiter perpendicular to R I, the motion of each moon and their places will appear to be in that line. Thus, if the exterior moon be at E or F, it will appear to be at I either upon or behind the center of Jupiter; if the moon moves from E to K, it will appear to have moved from I to L; and when it moves from K to C, it will appear to move from L to C. Again, while the ſatellite moves from C to M, it will appear to move from C to L; and as it goes from thence to F, it apparently moves from L to I. Thus alſo on the other ſide the orbit, while the ſatellite deſcribes the quadrant F D, its apparent motion will be from I to D; and then from D to I again, as it comes from D to E.

Whence, ſince this is the caſe of each ſatellite, it appears that while each ſatellite deſcribes the remote half of its orbit C F D, its apparent motion will be direct, or from weſt to eaſt along the line C D; and while it deſcribes the other half D E C, its apparent motion is retrograde, or from eaſt to weſt back again along the ſame line from D to C; ſo that each ſatellite traverſes the diameter of its orbit twice in each revolution.

The moons of Jupiter ſeverally ſhew the ſame phaſes to him as ours does to us. They diſappear from our ſight ſometimes, ſo that it is very rare to have all the four in view at once; nor is it poſſible to know which ſatellite in order you ſee, but from the knowledge of the theory and calculation; becauſe the remoteſt ſatellite may appear neareſt to Jupiter, and the contrary, as is evident from a view of the figure.

Theſe moons, like our own, ſuffer an eclipſe every time they come into the ſhadow of Jupiter, as at F. Alſo ſuppoſing the earth at T, the ſatellite at G will undergo an occultation behind the body of Jupiter, as is evident from the ſcheme. Again a ſatellite will ſometimes loſe its luſtre, as it paſſes over the enlightened diſk of its primary; as when it is at E and N, and the earth in R and T. Laſtly, one ſatellite at O may diſappear behind another at K, or cauſe another to diſappear behind it at M.

The obſervations by teleſcopes have been carried ſo far as to make it very probable, that all the ſatellites do really revolve about their own axis, by means of ſpots which they have diſcovered to belong to them, and which by their motion cauſe a great variety in the brightneſs of the ſatellites, and ſometimes do almoſt obſcure them: For which ſee Mr. Pound's obſervations on Jones's Abridgment of the *Philoſophical Tranſactions*, vol. IV. p. 307.

By means of Jupiter's ſatellites ſeveral noble problems in natural philoſophy have an eaſy and elegant ſolution; the firſt of which is to determine the ratio of the velocity of light: for the manner how this is done, ſee the article LIGHT. The ſecond is to determine the longitude of a place from any propoſed meridian; which is eaſily done by the following method: Let the moment of time in which the ſatellite enters the ſhadow of Jupiter be calculated for the given meridian from tables of its motion: then let the moment of time be well obſerved, when this immerſion happens at the propoſed place; the difference of theſe two moments turned into motion will give the longitude of the place, allowing 15 degrees for every hour, 1 degree for every 4 minutes of time, or 15 minutes of a degree for every minute of time. See LONGITUDE.

The third problem is to find the diſtance of Jupiter from the ſun. This is done as follows: Let the middle moment of the occulation of a ſatellite, as at G, be obſerved; and again the middle moment of the following at F; this will give the time in which the arch G F is deſcribed. Then ſay, as the time of the whole revolution is to the time now found, ſo is the whole circle of 360 degrees to the degrees and minutes contained in the arch

TIS; which is therefore the measure of the angle FIG, or its equal TIS, which is the parallactic angle at Jupiter; which being known at this distance of Jupiter from the sun, IS is easily found.

JURISDICTION, in law, signifies the power and authority with which any person is invested in administering justice in cases of complaint laid before him.

Jurisdictions are either ecclesiastical or secular; ecclesiastical belongs to bishops and their deputies.

Secular jurisdiction belongs to the king and his judges. The courts and judges at Westminster are not restrained to any county or place, they having jurisdiction all over England; but other courts are confined to their particular jurisdictions, which if they go beyond, all their proceedings become erroneous: as to inferior jurisdictions, they are of several sorts; one of which is to hold pleas, and the plaintiff may either sue there or in the king's courts. Another is the conusance of pleas; where a right is invested in the lord of the franchise to hold pleas. A third kind is an exempt jurisdiction, as where the king grants to the inhabitants of a particular city or corporation, the privilege of being sued only within their own city, &c.

JURISPRUDENCE, the science of what is just or unjust; or the knowledge of laws, rights, customs, statutes, &c. necessary for the administration of justice.

JURIS UTRUM, in law, is a writ in behalf of a clergyman, whose predecessor has alienated the lands belonging to his church.

JUROR, in law, signifies any person sworn on a jury.

JURY, a certain number of men sworn to enquire into and try a matter of fact, and to declare the truth upon such evidence as shall appear before them.

Juries are, in these kingdoms, the supreme judges in all courts and in all causes in which either the life, property, or reputation of any man is concerned: this is the distinguishing privilege of every Briton, and one of the most glorious advantages of our constitution; for as every one is tried by his peers, the meanest subject is as safe and as free as the greatest.

All criminal causes must first be tried by a grand jury, which commonly consists of twenty-four men of greater note than the petit jury, who are chosen indifferently out of the whole country, and no man can suffer the disgrace of being tried in any ignominious cause, without their first finding him guilty; if they find him innocent, he is immediately discharged; but if otherwise, they only find an indictment, on which he is tried, and finally acquitted or convicted by the verdict of the petit-jury, who are not only to be returned from the county, where the fact was done, but near neighbours, such as are most sufficient and least suspicious; to prevent partiality, the names of the persons impannelled are wrote on several pieces of paper of equal size, and delivered by the under-sheriff to the judge's marshal, who causes them to be rolled up, all in the same manner, and put together in a box, and when any cause is brought to trial, some indifferent person is to draw out twelve of these papers, and the persons whose names are drawn, if not challenged, are to be the jury to try the cause; and in case any are challenged, and set aside, or do not appear, then a further number is to be drawn till there is a full jury. See CHALLENGE.

When a juryman is sworn, he must not depart from the bar on any account whatsoever, till the evidence is given, without leave of the court; and if that be obtained, he must have a keeper with him. As soon as the whole evidence is summed up, the jury are to be kept together till they are all of one mind, and unanimous in bringing in their verdict, without being admitted to the speech of any person, and without meat, drink, fire, or candle. They are fineable if they agree to cast lots for their verdict, and also for being tampered with in relation to it: but as they are the sole judges of the fact, they are not fineable for giving a verdict contrary to what may appear plain evidence, because the law presumes that they may have some other evidence besides what is given in court; but where any corruption appears, a jury may be attainted for going contrary to evidence; and if a juror takes any thing either of the plaintiff or defendant for giving a verdict, he is to pay ten times as much as he has taken, or suffer a year's imprisonment; yet in trying causes, juries are to have their charges allowed them by the court. In all cases of difficulty it is safest for the jury to find the essential matter, and to leave it to the judge to determine how the law stands upon the fact.

Infants, persons of seventy years of age, and upwards, clergymen, apothecaries, &c. are exempted from serving upon juries; and barons, and all above them, are not to serve in any ordinary jury. Jurors, in London, must not only be housekeepers, but must have land or goods with one hundred pounds; and they may be examined on oath as to that point. 3 Geo. II. c. 25.

The qualifications of a jury-man for a county, is ten pounds per annum, either in freehold or copyhold-estate within the same county; but cities, boroughs, and corporate towns, are excepted by the statutes: however, no jury is obliged to appear upon a trial at Westminster, where the offence was committed thirty miles off, except it be required by the king's attorney-general. According to usage, the sheriff should return twenty-four jurors, in order to speed the trial in case of challenge, sickness, &c. and should he only return twelve, pursuant to the writ, he is liable to be amerced. By 4 and 5 W. and M. no sheriff, bailiff, &c. under the penalty of ten pounds, shall return any person to serve on a jury, who has not been duly summoned six days before his appearance, nor under the like penalty shall he accept of money or other reward for excusing the appearance of a juryman: jurymen neglecting to appear, shall be fined in a sum not exceeding five pounds, nor less than forty shillings, except they can give a reasonable excuse for their non-appearance; and in case a juryman does appear, but refuses to be sworn, or to give a verdict, an attachment may be issued against him.

Lists of jurors, according to the statutes of 4 and 5 W. and M. and 7 and 8 W. III. are now to be made from the rates of each parish, and fixed on the doors of churches, &c. twenty days before Michaelmas, that public notice may be given of persons omitted who are qualified, or of persons inserted who are not so; after which, the lists being settled by the justices of the peace at the quarter-sessions, duplicates are to be delivered to the sheriffs by the clerks of the peace; and the names contained in these lists must be entered alphabetically by the sheriffs in a book to be kept for that purpose, together with their additions and places of abode. The sheriffs are liable to be fined for returning other persons; and also if they return jurors that have served two years before. Sheriffs, on the return of writs of *venire facias*, are to annex a pannel of the names of a competent number of jurors, mentioned in the lists, and not less than forty-eight in any county, nor more than seventy-two, unless they are otherwise directed by the judges, which jurors shall be summoned to serve at the assizes, &c.

When it is conceived that an indifferent and impartial jury will not be returned by the sheriff, a special jury is allowed; in which case the court, upon a motion made, will order the sheriff to attend the secondary of the king's bench with his book of freeholders of the county, and the secondary is to mark a jury, in the presence of the attornies on both sides: also, if a cause of consequence is to be tried, the court of king's bench, on a motion upon an affidavit made, will make a rule for the secondary to name forty-eight freeholders, out of which each party is to strike out twelve, one at a time, the plaintiff's attorney beginning first, and the remainder of the jurors will be the jury for the trial: though the nomination of a special jury ought to be in the presence of the attornies on each side; yet in case either of them neglects, or refuses to attend, the secondary may proceed, and strike out twelve for the attorney that makes default. By 3 G. II. c. 25. on the motion of the prosecutor, plaintiff or defendant, on trials of issues on indictments, and in all actions whatsoever, the courts of Westminster are authorised to order a special jury to be struck in the same manner as upon trials at bar. Where a special jury is ordered by a rule of court, in any cause arising in a city, corporation, &c. this jury is to be taken out of the lists or books of the persons qualified, which are to be produced by the sheriffs, &c. before the proper officer. The same indulgence is granted both to merchants and foreigners; for where

where two merchants are plaintiff and defendant, the court may be moved for a jury of merchants to try the iſſue between them; and if either of the parties in the ſuit be an alien, the jury, at the deſire of the party, is to be compoſed of half foreigners and half Engliſh. See the articles PEERS and VERDICT.

JURY-MASTS, in the marine, certain ſpare maſts which are erected in a ſhip, when the others are carried away by the violence of a ſtorm, or otherwiſe.

JUST, a ſportive combat on horſeback, man againſt man, armed with lances.

JUSTICE, *Juſtitia*, in a moral ſenſe, is one of the four cardinal virtues, which gives every perſon his due.

JUSTICE, *Juſticiarius*, in a legal ſenſe, a perſon deputed by the king to adminiſter juſtice to his ſubjects, whoſe authority ariſes from his deputation, and not by right of magiſtracy.

JUSTICES *of the Peace* are perſons appointed by the king's commiſſion to keep the peace of the county in which they reſide; and ſome of theſe, who are of ſuperior rank or quality, are called juſtices of the quorum, and without the preſence or aſſent of theſe, or at leaſt one of them, no buſineſs of importance can be diſpatched.

JUSTICES *within Liberties*, are juſtices of the peace who have the ſame authority in cities or other corporate towns, as the others have in counties, and their power is the ſame, only theſe laſt have the aſſize of ale and beer, wood, and victuals, &c.

JUSTICE-SEAT is the higheſt foreſt court, always held before the lord chief juſtice in eyre of the foreſt; in which court fines are ſet for offences, and judgments given.

JUSTICIARY, or *Court of* JUSTICIARY, in Scotland, a court of ſupreme juriſdiction in all criminal caſes.

JUSTIFICATION, in law, ſignifies a maintaining, or ſhewing a ſufficient reaſon in court, why the defendant did what he is called to anſwer.

IVY, *hedera*, in botany, an evergreen plant, climbing and ſpreading on trees and old walls; with numerous ſlender twigs, and angular leaves. When grown old, the angles of the leaves diſappear, the plant becomes erect, produces flowers, ſmall and herbaceous, in autumn; and cluſters of black berries in winter.

The leaves of ivy have a very nauſeous taſte, and little or no ſmell. Haller ſays, they are commended in Germany againſt the atrophy of children. Among us, they are ſometimes applied externally by the common people, for drawing and healing running ſores, and keeping iſſues open.

The berries were ſuppoſed by the ancients to have a purgative and emetic quality; and later writers have recommended them, in ſmall doſes, as alexipharmic and ſudorific. It is ſaid, that in the London plague, the powder of them was given in vinegar or white wine with good ſucceſs. It is probable, however, that the virtue of this compound was rather owing to the vehicle than to the ivy-berries.

JYNX, the wry-neck, in ornithology, a genus of birds of the pye-kind, the beak of which is ſmooth, and the noſtrils hollowed: the tongue is very long, and of a rounded form, reſembling a worm: the toes are four in number, two before and two behind.

Of this genus there is only one known ſpecies, called, from its ſingular manner of twiſting its head about, the wry-neck. It is about the ſize of a lark, and is called by authors jynx, torquilla, turbo, &c.

K.

KAL — KAO

K, A double conſonant, and the tenth letter of the alphabet. It is borrowed from the Greek K, Kappa, which was made from the old Hebrew Caph, when reverted. It was but little uſed among the Latins; and Priſcian looked on it as ſuperfluous, and ſays it was never uſed except in words borrowed from the Greek; we ſeldom, it is true, meet with it in Latin authors, except in *kalendæ*.

This letter is formed in the voice by a guttural expreſſion of the breath through the mouth, together with a depreſſion of the lower jaw, and opening of the lips and teeth. It has much the ſame ſound as the hard ſound of C, and is generally uſed only before *i*, *e*, and *n*, in the beginning of words, where the hard ſound of *c* is formed, as in *kill*, *ken*, *knave*, &c.

K is alſo a numeral letter, denoting 250, according to this following verſe.

K quoque ducentos & quinquaginta tenebit.

When it had a ſtroke at top $\overline{K}$, it ſtood for 250,000.

KAABA, or CAABA. See CAABA.

KABBALA, or CABBALA. See CABBALA.

KÆMPFERIA, in botany, a genus of plants, the flower of which conſiſts of a ſingle petal, with a long ſlender tube, and the limb is divided into ſix ſegments: the fruit is a roundiſh and ſomewhat trigonal capſule, with three cells, each containing a conſiderable number of ſeeds.

The roots of this plant are the galangals of the ſhops. See GALANGALS.

KALI, glaſſwort, in botany, a plant with ſpreading, reddiſh, pretty thick branches; oblong, narrow, pointed, fleſhy leaves, like thoſe of the houſe-leeks; and imperfect flowers in the boſoms of the leaves, followed each by one ſeed ſpirally curled and incloſed in the cup. It is annual, and grows wild on the ſea-coaſts in the ſouthern parts of Europe, particularly of the Mediterranean.

This herb is very juicy, in taſte bitteriſh and remarkably ſaline. The expreſſed juice, and infuſions or decoctions of the leaves, are ſaid to be powerfully aperient and diuretic; and in this intention have by ſome been greatly recommended in hydropic caſes: half a dram of the juice is reckoned a ſufficient doſe. But the kali is principally regarded, on account of its yielding copiouſly, when burnt, the fixed alkaline ſalt called ſoda, or ſouda: an impure ſoda is prepared from it about Montpelier, where the plant is ſaid to be cultivated for this uſe in the ſalt marſhes; and a purer kind at Alicant in Spain, from a ſomewhat different ſpecies of kali. The ſalt called kelp, prepared among ourſelves from different marine plants, contains an alkali of the ſame kind, but more impure.

The ſoda is much milder in taſte than the common vegetable alkalies, and is in ſeveral other reſpects alſo very conſiderably different from them, being of the ſame nature with the mineral alkali or baſis of ſea-ſalt. It promiſes to be an uſeful article of the materia medica, and now begins to be introduced into practice in this country, as it has long been among the French.

Of the aſhes of kali is made ſope, glaſs, alkali-ſalt, potaſh, &c. See SOPE, GLASS, &c.

The method of preparing it is this: when dry, they burn it in certain pits, dug in the ground, which are cloſe covered up with earth, ſo that no air can come at the fire: by this means the matter is not only reduced to aſhes, but made into a very hard ſtone, like rock ſalt, which they are forced to break with hammers to get it out. The beſt ſort is in little dry ſtones, of a bluiſh grey colour, and full of little eyes or holes. See the article ALCALI.

KAOLIN, the name of one of the two ſubſtances, which are the ingredients of China-ware. The other, which is called petuntſe, is eaſily vitrifiable, and this kaolin is ſcarce at all ſo. Whence the fire compoſes, from a mixture of them both, a ſemivitrification, which is China-ware.

Mr. Reaumur had an opportunity of examining this ſubſtance, not in its native ſtate, but only in form of ſmall bricks, made out of a paſte of the powder of the native kaolin and water. He found it of a white colour, and ſprinkled all over with fine glittering particles; but theſe he did not judge to be fragments of a different ſubſtance mixed among the maſs, as are the ſmall flakes of talc in our clays and ſands; but that the whole maſs was compoſed of ſome ſtone reduced to powder and made into a paſte with water, and that theſe larger ſpangles were only coarſer particles of the powder; the examination of which he promiſed himſelf would diſcover what the ſtone was of which they were formed. And this was the more worthy a diligent enquiry, ſince the pentuntſe might eaſily be ſupplied by many of our own earths and ſands; nothing being required of that but a ſubſtance eaſily running into a white glaſs. But the difficulty of vitrifying this other ingredient renders it a thing much more difficult to be ſupplied by one of the ſame nature among ourſelves. The compariſon of theſe with other mineral ſubſtances ſoon proved that they were of the nature of talc; or, in other words, that kaolin was talc powdered, and made up into a paſte with water. And, to be aſſured whether the whole maſs was talc powdered, or any thing elſe with a mixture of talc, he ſeparated the particles of the kaolin by water, and found the ſmall ones wholly the ſame with the larger, and that the larger, when reduced to powder alone, made with water a paſte wholly the ſame with the kaolin.

It is well known that the fragments of talc have a great reſemblance to the pearly part of ſome ſhell-fiſhes; and hence unqueſtionably has ariſen the opinion of porcelain being made of ſea-ſhells; ignorant perſons having ſeen the talc or kaolin, and taken it for ſhelly matter. Talc has not yet been ſucceſsfully uſed in any of our European manufactures of porcelain; but it is eaſy to ſee, from many unanſwerable reaſons, that ſince China porcelain is made of a mixture of vitrifiable and an unvitrifiable matter, nothing is ſo likely to ſucceed with us, in the place of the laſt of theſe, as talc.

1. We know no ſubſtance in the foſſil world ſo difficult to reduce to glaſs as talc, which, if put into the ſtrongeſt

ſtrongeſt of our fires, in a crucible, is not to be vitrified, nor even calcined. 2. We know no ſubſtance which keeps ſo much brightneſs after having paſſed the fire as talc, or is of ſo pure a white; whence we may alſo learn that it is not to the petuntſe alone, that the China ware owes its whiteneſs, but that the kaolin is inſtrumental to the giving it that colour. 3. Talc is tranſparent, nay, and in ſome degree keeps its tranſparence after the action of the moſt violent fire. If we are to make porcelain of a vitrifiable and an unvitrifiable matter, mixed together, yet it is neceſſary that the unvitrifiable matter ſhould retain its tranſparence, otherwiſe it would obſcure the maſs; and talc is therefore the only known ſubſtance qualified for this purpoſe. Perſons who have been at the China works, ſay, that the porcelain is made of equal quantities of petuntſe and kaolin, and it is therefore a juſt and exact ſemi-vitrification. 4. Talc is well known to have a great flexibility and toughneſs, and, as it is found to preſerve this even after it has paſſed the fire, it is very probable, that it is owing to this property of the kaolin, that the China-ware is ſo much leſs brittle than glaſs. *Mem. Acad. Par.*

KEBLA, an appellation given by the Mahometans to that part of the world where the temple of Mecca is ſituated, towards which they are obliged to turn themſelves when they pray.

KECKLING, among ſailors, certain pieces of rope wound about the cable, to prevent it from being fretted or chafed by the ſhip's ſtem or bow.

KEDGE-ANCHOR, among ſailors, a ſmall anchor uſed in harbours and rivers, either to remove the ſhip from one place to another, by the help of certain tranſporting ropes, called warps, or to keep her ſteady as ſhe rides at anchor, eſpecially at the turn of the tide, when ſhe may come ſo nigh it as to entangle the flooks of it with her cable, if not kept from it by the kedge. See the article ANCHOR.

KEEL, in naval architecture, the principal piece of timber firſt laid upon the blocks, which ſupports the whole fabric of a ſhip in the ſame manner as the backbone ſuſtains the human body. When this cannot be had of a ſufficient depth in one piece, there is a ſtrong thick plank faſtened to the bottom, called the falſe-keel, which alſo ſerves to ſave the bottom of the main keel.

The keel of a ſhip of war is generally compoſed of four pieces bolted together lengthwiſe, and clinched. See the article SHIP-BUILDING.

The keels of the ſhips of war of the ancients were defended by pieces of wood nailed on the bilges, on either ſide, to prevent the keel from receiving damage when the ſhip was firſt launched into the water, or afterward ſtruck againſt any rock or ſand: theſe were called χελευσμάτα, in Latin *cunei*; according to Ovid,

Jamque labant cunei, ſpoliataque tegminæ ceræ
Rima patet.

The wedges break, and loſing all its wax,
A hole lets in the water.

KEEL is alſo a veſſel employed in divers parts of Northumberland to bring coals down the rivers to the ſhips into which they diſcharge them for tranſportation: theſe veſſels reſemble the coal barges on the river Thames, but are generally much ſtronger.

KEELSON, or KELSON, is the upper part of the keel, or that part of it which is within the ſhip. It is layed over the floor timbers, and bolted through them to the keel; this is alſo made like the keel of three or four pieces of timber ſcarfed together. See the article SHIP-BUILDING.

KEEPER *of the Foreſt*, an officer that has the chief management of every thing belonging to a royal foreſt, as well as the government of all the other officers. See FOREST.

KEEPER *of the Great Seal* is a lord by his office, is ſtiled lord-keeper of the great ſeal of Great Britain, and is always one of the privy council. All grants, charters and commiſſions of the king under the great ſeal, paſs through the hands of the lord-keeper, for without that ſeal, many of thoſe grants, &c. would be of no force; the king being, in the interpretation of the law, a corporation, and therefore paſſes nothing but by the great ſeal, which is alſo ſaid to be the public faith of the kingdom, being in the higheſt eſteem and reputation.

Whenever there is a lord-keeper, he is inveſted with the ſame place, authority, prehemmence, juriſdiction, or execution of laws, as the lord chancellor of Great Britain is veſted with.

KEEPER *of the Privy Seal* is alſo a lord by his office, through whoſe hands all grants, pardons, &c. paſs before they come to the great ſeal, and even ſome things paſs this officer's hands which do not paſs the great ſeal at all. This officer is likewiſe one of the privy-council, yet was anciently called clerk of the privy ſeal. His duty is to put the ſeal to no grant, &c. without a proper warrant, nor with warrant where it is againſt law, or inconvenient, but ſhall firſt acquaint the king therewith.

KELP, a fixed ſalt, or particular ſpecies of pot-aſh, procured by burning the weed kali. See the article KALI.

KERMES, round reddiſh-brown grains, about the ſize of peas; found in Spain, Italy, and the ſouthern parts of France, adhering to the branches of the ſcarlet oak. Theſe grains appear, when freſh, full of minute reddiſh ova or animalcules, of which they are the nidus, and which in long keeping change to a browniſh red powdery ſubſtance. They are cured by ſprinkling with vinegar before exſiccation: this prevents the exclution of the ova, and kills ſuch of the animals as are already hatched; which would otherwiſe become winged inſects, and leave the grain an empty huſk.

Freſh kermes yields upon expreſſion a red juice, of a light pleaſant ſmell, and a bitteriſh, ſubaſtringent, ſomewhat pungent taſte: this juice or ſyrup made from it, are brought from the ſouth of France, and ſometimes made uſe of as mild reſtringents and corroborants. An elegant cordial confection, for theſe intentions, is prepared in the ſhops, by diſſolving in the heat of a water bath, ſix ounces of fine ſugar in ſix ounces by meaſure of damaſk roſe water, then adding three pounds of the juice of kermes warmed and ſtrained, and after the whole has grown cold, mixing in half a ſcruple of oil of cinnamon: this confection is taken from a ſcruple to a dram or more; either by itſelf, or in juleps, with which it mingles uniformly without injuring their tranſparency. The dried grains, if they have not been too long kept, give out, both to water and to rectified ſpirit, the ſame deep red colour, and nearly the ſame kind of ſmell and taſte, with thoſe of the expreſſed juice.

KERMES-MINERAL.—The kermes mineral was a preparation of Glauber, which the king of France bought of Mr. de la Ligerie, and made public in 1720. That receipt was in the following form: take a pound of Hungarian antimony, broken into thin pieces, according to the direction of its ſpicula; four ounces of nitre, fixed by charcoal; and a pint of rain water: boil them two hours: then filtre the warm liquor, and, when it cools, the kermes precipitates. The ſame antimony undergoes the ſame operations with the remaining liquor, to which three ounces of fixed nitre, and a pint of water, are added. In a third boiling, two ounces of nitre, and a pint of water, are to be added to the former lixivium. The kermes thus obtained is about a drachm, which after being well edulcorated by waſhing it in water, and burning ſpirit of wine on it, is dried for uſe.

Mr. Geoffroy ſhews, by many experiments, that the kermes is the reguline part of the antimony, joined to a ſort of hepar ſulphuris. He teaches us a much eaſier way of preparing this medicine, thus: mix intimately the fine powder of two parts of antimony, and one of any fixed alkaline ſalt; melt thoſe materials in a crucible; then, having powdered them while hot, boil them two hours in a large quantity of water: after this, paſs the hot liquor through paper, receiving it into a veſſel, in which there is hot water; the kermes ſeparates, when it cools. The groſſer parts, which do not paſs through the paper, are to be boiled again, and filtrated again; and the operation is to be repeated a third time, by which ſix or ſeven drachms of kermes may be got out of every ounce of antimony. He ſays, he has ſeen effects, like to thoſe of mild kermes from antimony, reduced to ſuch a fine powder, that none of the ſhining ſpicula are to be ſeen; and

that the magiſtery of antimony, made by pouring ſpirit of nitre, or aqua regia, on the powder of antimony, and then edulcorating the maſs with water, has the ſame effects as kermes. *Mem. de la Acad. des Sciences.*

Half a grain, or a grain, of this powder, given every three or four hours, produces no violent effects; but, by increaſing the doſe, it may be made to vomit, purge, and ſweat. Some commend this medicine as the moſt univerſal reſolvent and deobſtruent; aſſuring us, that it almoſt infallibly cures pleuriſies, peripneumonies, aſthmas, catarrhs, anginæ, ſmall-pox, and many other diſeaſes. Others are as poſitive, that it heats and thickens the blood, thereby increaſing obſtructions, and is particularly hurtful in all inflammatory diſeaſes.

This preparation was famous in France, and known by the name of poudre des Chartereux, becauſe a Carthuſian monk, who got it from Mr. de la Ligerie, firſt brought it into vogue. See *Hiſt. de l' Acad. des Sciences* 1720, and the Memoirs for the ſame year, where it is ſaid that Glauber was looked upon as the firſt inventor of this remedy.

Its effect, like that of many other antimonial preparations, is very various, which is frequently owing, as Mr. Geoffroy obſerves, to the different manner and care of making it. He adds, that the more the kermes contains of a regulus eaſily revivified, the more it proves emetic. He alſo ſhews how to make a cinnabar with kermes and mercury, and to diſengage the vitriolic acid from the kermes. *See Mem. de l' Acad. des Sciences* 1734.

KERNING, among ſalt makers, the cryſtallizing of ſalt. See SALT.

KESTRIL, or KASTRIL, in ornithology, the yellow legged falcon, with a brown back, a ſpotted breaſt, and a rounded tail, with a broad black faſcia towards the end. It is a very beautiful bird, about the ſize of a pigeon, and very bold. It is known, among authors, by the names of tinnunculus and cenchris; and is alſo called in Engliſh, the ſtannel or windhover.

KETCH, in the marine, a veſſel with two maſts, viz. a main and mizen maſt.

The principal uſe of this ſort of ſhips is to bombard a place, being properly furniſhed with mortars, bombs, carcaſes, &c. for this employment, and built remarkably ſtrong to encounter the ſhock of firing ſhells for a continuance.

KETTLE-DRUMS, in the art of war. See the article DRUM.

KEVELS, in ſhip-building, a ſort of frame compoſed of two pieces of wood thruſt into a third, which is bolted to the inſide of the ſhip: the uſe of which is to faſten ſome rope to, but more particularly the main and fore ſheets. See the article SHEET.

KEY, *Clavis*, a well known inſtrument for opening and ſhutting the locks of doors, cheſts, bureaus, and the like. See LOCK.

The names of the ſeveral parts of a key are theſe: A (plate LXXVII. *fig.*5.) is the pin-hole, drilled into the end of the ſhank H; B is the ſtep, or dap-ward; C, the hook-ward; D, the middle-ward; E E, the croſs-ward; F, the main-ward; G G, croſs-ward; I, the pot; K, the bow-ward; L, the bow, or handle; and B F E D, &c. the piece of ſteel, containing the wards, is called the bit of the key. Keys are prohibited to be imported.

KEY, in muſic, a certain fundamental note, or tone, to which the whole piece, be it in concerto, ſonata, cantata, &c. is accommodated, and with which it uſually begins, but always ends. See CLEF.

To give a diſtinct notion of the key, we muſt obſerve, that the octave contains in it the whole principles of muſic, both with reſpect to conſonance and melody; and that if the ſcale be continued to a double octave, there will in that caſe be ſeven different orders of the degrees of an octave, proceeding from the ſeven different letters, with which the terms of the ſcale are marked. Any given ſound therefore, i. e. a ſound of any determinate pitch of tune, may be made the key of the piece, by applying it to the ſeven natural notes ariſing from the diviſion of an octave, and repeating the octave above and below at pleaſure: the given note is applied as the principal note or key to the piece, by making frequent cloſes or cadences upon it; and in the progreſs of the melody, no other than theſe ſeven natural ſounds can be admitted, while the piece continues in that key.

Here too it muſt be added with reſpect to the two different diviſions of the octave, that a ſound may belong to the ſame key, that is, have a juſt muſical relation to the ſame fundamental in the one kind of diviſion, and be out of the key in reſpect of the other. Now a piece of muſic may be carried through ſeveral keys, that is, it may begin in one key, and be led out of that into another, by introducing ſome ſound foreign to the firſt, and ſo on to another: but a regular piece of muſic muſt not only return to the firſt key, but thoſe keys too muſt have a particular connection with the firſt. It may be added, that thoſe other keys muſt be ſome of the natural ſounds of the principal key, though not any of them at pleaſure.

From the diſtinctions already obſerved, it is evident, that there are but two different ſpecies of keys, which ariſe according as we join the greater or leſſer third, theſe being always accompanied with the ſixth and ſeventh of the ſame ſpecies; the third greater, for inſtance, with the ſixth and ſeventh greater, and the third leſſer with the ſixth and ſeventh leſſer.

And this diſtinction is expreſſed under the name of a ſharp key, which is that with the third greater, &c. and the flat key with the third leſſer, &c. whence it is plain, that how many different caſes ſoever there be in a piece, there can be but two keys, if we conſider the eſſential difference of keys: every key being either flat or ſharp, and every ſharp key being the ſame as to melody, as well as a flat one.

KEY is alſo uſed for an index, or explanation of a cipher. See CIPHER.

KEYS likewiſe denote thoſe little pieces in the forepart of an organ, ſpinnet, or harpſicord, whereby the jacks are played, ſo as to ſtrike the ſtrings of the inſtrument, and wind is given to the pipes by raiſing and ſinking the ſucker of the ſound-board.

KEY-STONE *of an Arch, or Vault*, that placed at the top or vertex of an arch, to bind the two ſweeps together.

KIDNIES, *Renes*, in anatomy, two pretty ſolid, glandular bodies, ſituated in the poſterior part of the cavity of the abdomen, on each ſide of the lumbar vertebræ, between the laſt falſe ribs and oſſa ilium.

The right kidney lies under the great lobe of the liver, and is conſequently lower than the left, which lies under the ſpleen. The figure of the kidney reſembles that of a large bean; being convex on one ſide, and concave on the other; the concave ſide is turned to the vertebræ, and the convex the oppoſite way. Their length anſwers to the diſtance between the laſt falſe rib and os ilium; they are about half as broad as long, and half as thick as broad.

The deſcending aorta and inferior vena cava lie between the kidnies, pretty cloſe to the bodies of the vertebræ and to each other; the artery being on the left hand, and the vein on the right. Each of theſe large veſſels ſends out, tranſverſely, towards each ſide, commonly one capital branch, which enters the ſinus and depreſſion of the kidney by ſeveral ramifications. Theſe veſſels were by the ancients called emulgent arteries and veins, but are rather renal veins and arteries. There are more than one of each kind, particularly in the arteries; ſometimes on one ſide only, and ſometimes on both.

The left renal artery is ſhorter than the right, becauſe the aorta lies neareſt the left kidney; and the left renal vein is longer than the right, becauſe the vena cava lies fartheſt from the left kidney. The veins lie more anteriorly than the arteries.

Each renal artery is ſurrounded by a nervous net work called plexus renalis, furniſhing a great number of filaments to the kidnies, that come partly from the ſemilunar ganglions of two great ſympathetic nerves, and partly from the plexus hepaticus and ſplenicus. This renal plexus alſo ſends filaments round the renal veins.

The kidnies are ſurrounded by a very looſe, membranous, and cellular covering called membrana adipoſa, which is not a duplicature of the peritonæum, the true membranous lamina of which covers only the foreſide of the kidnies. The only coat they have is the cellular ſubſtance,

ſubſtance, which likewiſe inveſts the renal arteries and veins like a vagina.

The proper membrane of the kidnies conſiſts of two laminæ, between which there is alſo a very fine cellular ſubſtance, as appears upon blowing.

The external lamina is very thin, adhering cloſely to the internal by means of the cellular ſubſtance. The internal lamina penetrates every where into the ſubſtance of the kidney.

In children the convex ſurface is divided into ſeveral lobes, almoſt as in oxen and calves; and in grown perſons we ſometimes obſerve the ſame inequalities.

The blood-veſſels entering the kidnies are ramified every way; and theſe ramifications ſend out the capillary branches all the way to the ſurface thereof: ſometimes theſe two ramifications penetrate to the membrana adipoſa, communicating there with the adipoſe veins and arteries.

The proper membrane having ſurrounded the kidney all the way to the ſinus, joins the veſſels there, and accompanies all their ramifications through the body of the kidney, like a capſula, and contributes in part to form the pelvis and calices or infundibula.

Sometimes, but rarely, a conſiderable veſſel goes in or comes out from the convex ſurface of the kidney, and then there is a depreſſion by which the proper membrane enters, and communicates with that portion which goes in by the ſinus.

The tunica adipoſa terminates at the ſinus in the interſtices between the ramifications.

There are three kinds of ſubſtances in the kidney, that may be ſeen when it is cut through the great curvature: 1. An exterior, which is thick, granulated, and in a manner cortical. 2. A middle ſubſtance, which is medullary and radiated, called ſtriata, ſulcata, or tubularis; and 3. An inner ſubſtance, which is only a continuation of the ſecond, and terminates on the inſide by papillæ; and for that reaſon is called papillaris.

By the microſcope the cortical ſubſtance is obſerved to be of a ſpongy, granulated, and waving texture, of a bright whitiſh grey-colour; and likewiſe great numbers of ſmall red corpuſcles, more or leſs round, are to be ſeen, and diſpoſed almoſt like bunches of currants.

The other two ſubſtances are but one and the ſame maſs, of a more reddiſh colour; the convex ſide of which riſes into narrow tubercles, lodged in the ſame number of cavities. The radiated ſtriæ are afterwards continued to the papillary portion, and the papillæ form ſo many centers of theſe radii, oppoſite to the tubercles. The medullary ſubſtance has arterial and venal arches that ſend capillaries on all hands, and its colour is more or leſs red.

The papillæ are often a little paler than the medullary ſubſtance. They are ten or twelve in number, reſembling the ſame number of cones, with very broad baſes and obtuſe apices. At the point of each papilla may be ſeen ſeveral very ſmall holes, through which little drops run, when the papillæ are compreſſed; being little drops of urine that are filtered and diſcharged at theſe orifices.

Each papilla lies in a kind of calyx or infundibulum, which opens into a common cavity, called the pelvis. This cavity in men is not uniform, but diſtinguiſhed into three portions, each of which contains a certain number of infundibula, together with the papillæ that lie therein.

At the place where theſe infundibula ſurround the baſes of the papillæ, they ſend productions into the medullary ſubſtance of the kidney, which accompany the blood-veſſels, and ſerve for vaginæ to all the vaſcular arches, and their different ramifications, quite as far as the ſurface of the kidney.

KILDERKIN, a liquid meaſure, containing two firkins. See FIRKIN.

KINDRED, in law, perſons related to another, whereof the law of England reckons three degrees or lines, viz. the deſcending, aſcending, and collateral line.

On there being no kindred in the deſcending line, the inheritance paſſes to the collateral one. See INHERITANCE.

KING, in the general acceptation of the word, is a perſon who has a ſupreme authority, with the power of levying taxes, making laws, and enforcing an obedience to them: but in England, which is a limited monarchy, the power of the king is greatly reſtrained; which is ſo far from diminiſhing his honour, that it adds a glory to his crown; for while other kings are abſolute monarchs over innumerable multitudes of ſlaves, the king of England has the diſtinguiſhed glory of governing a free people, the leaſt of whom is protected by the laws: he has great prerogatives, and a boundleſs power in doing good; and is at the ſame time only reſtrained from acting inconſiſtently with his own happineſs, and that of his people. He has all the enſigns of royalty, and all the marks of ſovereignty: but while he has the power of making treaties, of ſending and receiving ambaſſadors, of conferring titles of honour, creating privy counſellors, officers of ſtate, and judges, and may raiſe men and arms both for ſea and land, he cannot force his ſubjects to maintain them, or raiſe one tax by his ſole authority: he has the privilege of coining money, but he cannot force the meaneſt ſubject to part with his property; he can pardon a criminal, but he cannot put a ſubject to death, till he is condemned by his peers: he may at his pleaſure call, continue, prorogue, and diſſolve parliaments, and without his royal aſſent no bill in parliament can paſs into a law; yet he can neither act contrary to law, nor make new laws by his ſole authority; on the contrary, he may even be ſued and caſt in his own courts.

KING'S-BENCH, in law, a court held in Weſtminſter-Hall, ſo called, in regard the king is ſuppoſed to ſit in perſon as judge of the court, and may do ſo whenever he pleaſes; wherefore all writs, &c. in this court are made returnable *coram nobis*, and not *coram juſticiariis noſtris*, as in the Common-Pleas.

The judges are the lord chief juſtice, and three other puny juſtices. Here are principally determined matters relating to the crown and the peace. When any are aggrieved by an order of juſtices or quarter ſeſſions, they have recourſe hither: the rights of election of mayors, bailiffs, conſtables, &c. are, upon mandamus's, ſettled here, and prohibitions iſſued to ſtay proceedings in the eccleſiaſtical, admiralty, or other inferior court. Here any debt or contract may be ſued for, as well as in any other court, and may as expeditiouſly proceed.

Books of KINGS, two canonical books of the Old Teſtament, ſo called becauſe they contain the hiſtory of the kings of Iſrael and Judah, from the beginning of the reign of Solomon, down to the Babyloniſh captivity, for the ſpace of near ſix hundred years. The firſt book of Kings contains the latter part of the life of David, and his death; the flouriſhing ſtate of the Iſraelites under Solomon, his building and dedicating the temple of Jeruſalem, his ſhameful defection from the true religion, and the ſudden decay of the Jewiſh nation after his death, when it was divided into two kingdoms: the reſt of the book is taken up in relating the acts of four kings of Judah, and eight of Iſrael.

The ſecond book, which is a continuation of the ſame hiſtory, is a relation of the memorable acts of ſixteen kings of Judah, and twelve of Iſrael, and the end of both kingdoms, by the carrying of the ten tribes captive into Aſſyria by Salmanaſer, and the other two into Babylon by Nebuchadnezzar.

It is probable that theſe books were compoſed by Ezra, who extracted them out of the public records which were kept of what paſſed in that nation.

KING'S-FISHER, *Iſpida*, in ornithology. See the article ISPIDA.

KINK, a ſort of twiſt or turn in the cable, owing to its being very ſtiff, or not well cleared at the time of its running out of the ſhip when the anchor is let fall from the bow.

KIRK, a Saxon term, ſignifying the ſame with church. See the article CHURCH.

KIRK-SESSIONS, an inferior church-judicatory, in Scotland, conſiſting of the miniſters, elders, and deacons of a pariſh.

KITCHEN GARDEN, a piece of ground laid out for the cultivation of fruit, herbs, pulſe, and other vegetables uſed in the kitchen.

A kitchen garden ought to be ſituated on one ſide of the

houſe, near the ſtables, from whence the dung may be eaſily conveyed into it; and after having built the wall, borders ſhould be made under them, which according to Miller, ought to be eight or ten feet broad: upon thoſe borders expoſed to the ſouth, many ſorts of early plants may be ſown; and upon thoſe expoſed to the north, you may have ſome late crops, taking care not to plant any ſort of deep-rooting plants, eſpecially beans and peas, too near the fruit-trees. You ſhould next proceed to divide the ground into quarters; the beſt figures for theſe is a ſquare, or an oblong, if the ground will admit of it; otherwiſe they may be of that ſhape which will be moſt advantageous to the ground; the ſize of theſe quarters ſhould be proportioned to that of the garden; if they are too ſmall, your ground will be loſt in walks, and the quarters being encloſed by eſpaliers of fruit-trees, the plants will draw up ſlender, for want of a more open expoſure. The walks ſhould alſo be proportioned to the ſize of the ground; theſe in a ſmall garden ſhonld be ſix feet broad, but in a larger one ten; and on each ſide of the walk there ſhould be allowed a border three or four feet wide, between it and the eſpalier, and in theſe borders may be ſown ſome ſmall ſallads, or any other herbs that do not take deep root, or continue long: but theſe quarters ſhould not be ſown or planted with the ſame crop two years together. In one of theſe quarters, ſituated neareſt to the ſtables, and beſt defended from the cold winds, ſhould be the hot-beds, for early cucumbers, melons, &c. and to theſe there ſhould be a paſſage from the ſtables, and a gate through which a ſmall cart may enter. The moſt important points of general culture conſiſt in well digging and manuring the ſoil, giving a proper diſtance to each plant, according to their different growths, as alſo in keeping them clear from weeds; for this purpoſe you ſhould always obſerve to keep your dung-hills clear from them; if this is not done, their ſeeds will be conſtantly brought in, and ſpread with the dung.

KITE, *Milvus*. See MILVUS.

KNAVE, in old law books, an appellation given to a man ſervant, or even to a male child.

KNEE, *Genu*, in anatomy, the articulation of the thigh and leg-bones. See the articles FEMUR, TIBIA, PATELLA, &c.

The two principal motions of this joint are flexion and extenſion: in the former of theſe the leg may be brought to a very acute angle with the thigh, by the condyles of the thigh bone being round and ſmoothed ſo far backwards; and in performing this, the patella is pulled down by the tibia. When the leg is to be extended, the patella is drawn upwards, and the tibia forwards, by the extenſor-muſcles, which, by means of the protuberant joint, and this thick bone with its ligament, have the chord with which they act, at a conſiderable angle, and therefore act with advantage; but, in order that the body may be ſupported by a firm perpendicular column, they are reſtrained by the poſterior croſs-ligament, from pulling the leg farther than to a ſtraight line with the thigh; and when this is done, the thigh and leg are almoſt as immoveable as if they were one continued bone: but when the joint is a little bent, the poſterior ligament is relaxed, and the patella not tightly braced; therefore the ſuperficial cavities of the tibia will allow this bone to be moved a little to either ſide, or with a ſmall rotation; which is done by the motion of the external cavity backwards and forwards on the internal, which ſerves as a kind of axis. The rotation of the leg outwards is of great advantage to us in croſſing our legs on ſeveral neceſſary occaſions; though it is wiſely ordered by Providence, that this motion ſhould not be very great, ſince this would have occaſioned frequent luxations. While all theſe motions are performing, the only part of the tibia that moves immediately on the condyles, is only ſo much as is within the cartilaginous rings, which by the thickneſs of their outſides, make the cavities of the tibia more horizontal, by raiſing their external ſide, where the ſurface of the tibia ſlants downwards; by which means the motions of this joint are more equal and ſteady than they would otherwiſe have been. The cartilages are fitted to do this good office in the different motions and poſtures of the member, by being capable of changing a little their ſituation; and this alſo contributes to make the motions larger and quicker.

KNEE *of the Head*, in ſhip-building, a large piece of timber fayed and bolted to the ſtem, on which the figure or image of the head reſts: by reaſon of its great breadth at the upper part, it is compoſed of ſeveral pieces: it is let into the head, and faſtened to the ſhips bows on each ſide by knees, which are called the cheeks of the head: it is alſo ſcarfed to the head of the fore-foot, and faſtened to the ſtem by a knee, called a ſtandard, in the form of a K. This is commonly called cut-water by ſeamen. See the article CUT-WATER.

KNEES, in ſhip-building, certain crooked pieces of timber, one leg or arm of which is bolted to the beams, and the other to the ſhip's ſide. They are either lodging or hanging: the hanging knees are fayed up and down; and the others fore and aft on the inſide of the ſhip, reſting upon clamps.

KNIGHT, *Eques*, among the Romans, a perſon of the ſecond degree of nobility, following immediately that of the ſenators.

KNIGHT, a perſon who, on account of ſome martial feat, or notable action, is by the king raiſed to a rank above a gentleman.

The original High Dutch word *knecht*, ſignifies a ſervant, as we find it ſtill meant by knight of the ſhire; and afterwards it denoted a military man, or horſeman, as being uſually employed on horſeback. In our common law, they are called *milites*, as commonly holding lands in knight-ſervice to ſerve the king in his wars.

Knights were originally ſaid to be adopted, now we call it dubbed, as being ſuppoſed, in ſome meaſure, the ſons of him who knighted them.

The principal ceremonies at the creation of a knight, were a box on the ear, a ſtroke with a ſword on the ſhoulder, putting on a ſhoulder-belt, gilt ſword, ſpurs, &c. after which, being properly armed, he was ſolemnly led to the church.

Camden deſcribes the manner of making knights batchelors, which is the loweſt, though the moſt ancient order of knighthood in England; the perſon kneeling was gently ſtruck on the ſhoulder, and accoſted by the prince in theſe words, "Riſe, and be a knight in "the name of God." See the articles BATCHELOR, BANNERET, BARONET, BATH, GARTER, &c.

KNIGHT alſo denotes a perſon admitted into any order, with certain marks of diſtinction, as the knights of the garter, of the elephant, of the thiſtle; of the Holy Ghoſt, Malta, &c.

KNIGHTS-ERRANT, a pretended order of chivalry, much talked of in old romances, being a kind of heroes that travelled the world in ſeach of adventures, redreſſing wrongs, reſcuing damſels, and taking all occaſions of ſignalizing their proweſs. Of this kind of knights was Don Quixote, the hero of a celebrated romance, known by that name. This romantic bravery of the old knights was heretofore the chimera of the Spaniards.

KNIGHTS *of the Shire*, or KNIGHTS *of Parliament*, in the Britiſh polity, are two knights or gentlemen of eſtate, who are elected, on the king's writ, by the freeholders of every county, to repreſent them in parliament.

The qualifications of a knight of the ſhire, is to be poſſeſſed of 600 l. per ann. in a freehold eſtate. Their expences during their ſitting, were, by a ſtatute of Henry VIII. to be defrayed by the county; but this is now ſcarce ever required.

KNIGHT-MARSHAL, an officer in the king's houſehold, who has juriſdiction and cognizance of any tranſgreſſion within the king's houſhould and verge; as alſo of contracts made there, whereof one of the houſe is party.

KNIGHT-HEADS, in ſhip-building, two ſtrong pieces of timber placed on each ſide of the deck of a merchant-ſhip. They are uſed to ſupport the windlaſs, or roller, by which the cable is wound into the ſhip; and as each of them is formed of two pieces, they can be occaſionally taken down and ſeparated, to remove the cable from off the windlaſs, which reſts upon, and turns round in the knight-heads: they are otherwiſe called bits, and in this ſenſe the upper-part only is called the knight-head.

KNOTTING, among ſailors, untwiſting the ends of a rope, and interweaving them curiouſly amongſt each other, ſo as to form knots of various ſhapes; among which

which they number the diamond-knot, the wall-knot, or walnut, the roſe-knot, bowline-knot, double diamond-knot, &c.

KNOWLEDGE, according to Mr. Locke, conſiſts in the perception of the connection and agreement, or diſagreement and repugnancy of our ideas: and ſo it ſtands contradiſtinguiſhed from ignorance.

The whole ſtock of our knowledge conſiſts of four heads, namely, identity or diverſity, relation, co-exiſtence, and real exiſtence.

As to the identity or diverſity of our ideas, it is the firſt act of the mind to perceive its own ideas, and, ſo far as it perceives them, to know what each is, and thereby find out their difference.

The next kind of agreement or diſagreement in our ideas is co-exiſtence or non-co-exiſtence in the ſame ſubject, and this belongs particularly to ſubſtances.

The fourth ſort is that of actual exiſtence, agreeing to any idea. The mind becomes poſſeſſed of truth ſeveral ways, which conſtitute ſo many different ſpecies of knowledge. Thus, when the mind has a preſent view of the agreement or diſagreement of any of its ideas, or relation they bear to one another, this is called actual knowledge.

Secondly, a man is ſaid to know a propoſition, when having once evidently perceived the agreement or diſagreement of the ideas of which it conſiſts, and ſo lodged it in his memory, the mind aſſents to it without any heſitation, whenever it comes to be reflected on again; and this may be called habitual knowledge. Of this there are two ſorts; the one conſiſts of ſuch truths laid up in the memory, as, whenever they occur to the mind, it actually perceives their relation by an immediate view: the other is of ſuch truths of which the mind having been convinced, it retains the memory of the conviction, without the proofs.

Degrees and Extent of KNOWLEDGE. The clearneſs of our knowlege ſeems to lie in the different ways the mind has of perceiving the agreement or diſagreement of its ideas. When the mind perceives it immediately, it is intuitive knowledge. On this intuition depends all the certainty and evidence of our other knowledge.

The next degree of knowledge is by the intervention of other ideas, to diſcover the agreement or diſagreement. Thoſe intervening ideas are called proofs, and, where the agreement and diſagreement is plainly perceived, it is called demonſtration; and a quickneſs in the mind to find theſe proofs is called ſagacity.

This knowledge, though it be certain, is not ſo evident as intuitive knowledge. Before demonſtration there was a doubt, which in intuitive knowledge cannot happen to the mind. Now in every ſtep that reaſon makes in demonſtrative knowledge, there is an intuitive knowledge of that agreement or diſagreement it ſeeks with the next intermediate idea, which it uſes as a proof. This intuitive perception of the agreement or diſagreement of the intermediate ideas in each ſtep muſt alſo be exactly carried in the mind.

It has been generally taken for granted, that mathematics alone are capable of demonſtration; but to have ſuch an agreement or diſagreement as may be intuitively perceived, being not the privilege of the ideas of number, extenſion, figure, and modes alone, it may poſſibly be the want of due method and application in us, and not of ſufficient evidence in things, that demonſtration has been thought to have ſo little to do in other parts of knowledge. The reaſon why it has been generally ſuppoſed to belong to theſe only, is, becauſe, in comparing the equality or exceſs, the modes of numbers have every the leaſt difference clearly perceivable: and in extenſion, though every the leaſt exceſs is not ſo perceivable, yet the mind has found out ways to diſcover the juſt equality of two angles, &c. Add to this, that both numbers and figures can be ſet down by viſible marks. But in other ſimple ideas, whoſe modes and differences are counted by degrees, and not quantity, we have not ſo accurate a diſtinction of their differences, as to perceive their juſt equality or leaſt differences.

Thus not knowing what number of particles nor what motion of them is fit to produce any preciſe degree of whiteneſs, becauſe we have no certain ſtandard to meaſure them by, nor means to diſtinguiſh every the leaſt difference, the only help we have is from our ſenſes, which here fail us. But where the difference is ſo great, as to produce ideas clearly diſtinct, theſe ideas, as we ſee in colours of different kinds, are as capable of demonſtration, as ideas of number and extenſion. And this holds in all ſecondary qualities.

Whatever comes ſhort of intuition and demonſtration, is but faith or opinion, not knowledge, at leaſt in all general truths. As we are invincibly conſcious to ourſelves of a different perception, when we look on the ſun in the day, and think on it by night, we may add to the two former ſorts of knowledge this alſo of the exiſtence of particular external objects by that conſciouſneſs we have of the actual entrance of ideas from them; ſo that there is a third degree of knowledge, which may be called ſenſitive.

But ſince our knowledge is founded on our ideas only, will it follow, that it muſt be conformable to our ideas? We anſwer no; for our knowledge conſiſting in the perception of the agreement or diſagreement of any two ideas, clearneſs or obſcurity conſiſts in the clearneſs or obſcurity of that perception, and not in the clearneſs or obſcurity of the ideas themſelves: but obſcure and confuſed ideas can never produce any clear or diſtinct knowledge; becauſe, as far as they are ſo, the mind can never perceive whether they agree or diſagree.

Extent and Limits of Human KNOWLEDGE. 1. It is evident that we can have no knowledge farther than we have perception of the agreement or diſagreement of our ideas, whether by intuition, demonſtration, or ſenſation. 2. We cannot have an intuitive knowledge that ſhall extend itſelf to all our ideas and all that we know about them, becauſe we cannot examine and perceive all the relations they have to each other; thus we cannot intuitively perceive the equality of two extenſions, the difference of whoſe figures makes their parts incapable of an exact immediate application. 3. Demonſtrative knowledge cannot reach to the whole extent of our ideas, becauſe we cannot always find ſuch proofs as will connect them together, with an intuitive knowledge in all the parts of the deduction. Thus, though we have the ideas of a ſquare, a circle, and equality, yet we, perhaps, ſhall never be able to find a ſquare exactly to a circle. The affirmations, or negations we make concerning the ideas we have, being reduced by Mr. Locke to theſe four, viz. identity, co-exiſtence, relation, and real exiſtence, he examines how far our knowledge extends to each of theſe.

1. As to identity and diverſity, our intuitive knowledge is ſo far extended as our ideas themſelves, and there can be no idea in the mind which it does not preſently, by an intuitive knowledge, perceive to be what it is, and to be different from any other.

2. As to the agreement or diſagreement of our ideas of co-exiſtence, our knowledge herein is very defective, though the greateſt and moſt material part of our knowledge concerning ſubſtances conſiſts in it.

As to the powers of ſubſtances, which makes a great part of our enquiries about them, our knowledge reaches little further than experience, becauſe they conſiſt in a texture and motion of parts which we cannot by any means come to diſcover.

3. As to the third ſort, the agreement or diſagreement of our ideas in any other relation; this is the largeſt field of knowledge, and it is hard to determine how far it may extend. This part depending on our ſagacity in finding intermediate ideas, that may ſhew the habitudes and relations of ideas, it is difficult to tell when we are at an end in ſuch diſcoveries.

4. As to the fourth part of knowledge, viz. of the real actual exiſtence of things, we have an intuitive knowledge of our own exiſtence, a demonſtrative knowledge of the exiſtence of God, and a ſenſitive knowledge of the objects that preſent themſelves to our ſenſes. See the article EXISTENCE.

Reality of Human KNOWLEDGE. It is evident, ſays Mr. Locke, that the mind knows not things immediately, but by the intervention of the ideas it has of them. Our knowledge therefore is real only ſo far as there is a conformity between our ideas and the reality of things.

But how ſhall we know when our ideas agree with things themſelves? It is anſwered, there are two ſorts of ideas that we may be aſſured agree with things: theſe are,

1. Simple ideas; which, ſince the mind can by no means make to itſelf, muſt be the effect of things operating upon the mind in a natural way, and producing therein thoſe perceptions which, by the will of our Maker, they are ordained and adapted to. Hence it follows, that ſimple ideas are not fictions of our fancies, but the natural and regular productions of things without us really operating upon us, which carry with them all the conformity our ſtate requires, which is to repreſent things under thoſe appearances they are fitted to produce in us. Thus the idea of whiteneſs, as it is in the mind, exactly anſwers to that power which is in any body to produce it there. And this conformity between our ſimple ideas and the exiſtence of things, is ſufficient for real knowledge. See IDEA.

2. All our complex ideas, except only thoſe of ſubſtances, being archetypes of the mind's own making, and not referred to the exiſtence of things as to their originals, cannot want any conformity neceſſary to real knowledge.

3. But the complex ideas which we refer to archetypes without us, may differ from them, and ſo our knowledge about them may come ſhort of being real, and ſuch are our ideas of ſubſtances. Theſe muſt be taken from ſomething that does or has exiſted, and not be made up of ideas arbitrarily put together, without any real pattern. Herein, therefore, is founded the reality of our knowledge concerning ſubſtances, that all our complex ideas of them muſt be ſuch, and ſuch only, as are made up of ſingle ones, as have been diſcovered to co exiſt in nature; and our ideas being thus true, though not perhaps very exact copies, are the ſubjects of real knowledge of them. Whatever ideas we have, the agreement we find they have with others, will be knowledge: if thoſe ideas be abſtract, it will be general knowledge; but to make it real concerning ſubſtances, it muſt be taken from the real exiſtence of things: wherever therefore, we perceive the agreement or diſagreement of our ideas, there is certain knowledge, and wherever we are ſure theſe ideas agree with the reality of things, there is certain real knowledge.

Improvement of Human KNOWLEDGE. The ſentiments of the ſame author upon the improvements of our knowledge are as follow: It being the received opinion among men of letters, that maxims are the foundations of all knowledge, and that ſciences are each of them built upon certain præcognita, from whence the underſtanding was to take its riſe, and by which it was to conduct itſelf in its enquiries in the matters belonging to that ſcience, the beaten road of the ſchools was to lay down, in the beginning, one or more general propoſitions called principles or foundations, whereon to build the knowledge that was to be had of that ſubject.

That which gave occaſion to this way of proceeding, he ſuppoſes to have been the good ſucceſs it ſeemed to have in the mathematics, which of all other ſciences have the greateſt clearneſs, certainty, and evidence in them; but if we conſider it, we ſhall find that the great advancement and certainty of real knowledge men arrive at, in theſe ſciences, was not owing to the influence of theſe principles, but to the clear, diſtinct, and complete ideas their thoughts were employed about, and the relation of equality and exceſs ſo clear between ſome of them, that they had an intuitive knowledge, and by that way to diſcover it in others, and this without the help of thoſe maxims. See AXIOM.

The way to improve in knowledge, is not to ſwallow principles with an implicit faith, and without examination, which would be apt to miſlead men, inſtead of guiding them into truth; but to get and fix in our minds clear and complete ideas, as far as they are to be had, and annex to them proper and conſtant names, and thus barely by conſidering our ideas, and comparing them together, and obſerving their agreement or diſagreement, their habitudes and relations, we ſhall get more true and clear knowledge by the conduct of this one rule, than by taking up principles, and thereby putting the mind into the diſpoſal of others.

We muſt therefore, if we proceed as reaſon adviſes, adapt our methods of enquiry to the nature of the ideas we examine, and the truth we ſearch after. General and certain truths are only founded in the habitudes and relations of abſtract ideas; therefore a ſagacious methodical application of our thoughts, for the finding out theſe relations, is the only way to diſcover all that can with truth and certainty be put into general propoſitions. By what ſteps we are to proceed in theſe, is to be learned in the ſchools of the mathematicians, who from very plain and eaſy beginnings, by gentle degrees, and a continued chain of reaſonings, proceed to the diſcovery and demonſtration of truths, that appear at firſt ſight above human capacity. This may reaſonably be ſaid, that if other ideas, that are real as well as nominal eſſences of their ſpecies, were purſued in the way familiar to mathematicians, they would carry our thoughts farther, and with greater evidence and clearneſs, than probably we are apt to imagine.

In our knowledge of ſubſtances, we are to proceed in quite a different method; the bare contemplation of their abſtract ideas, which are but nominal eſſences, will carry us but a very little way in the ſearch of truth and certainty: here experience muſt teach us what reaſon cannot; and it is by trying alone that we can certainly know what other qualities co-exiſt with thoſe of our complex idea; for inſtance, whether that yellow, heavy, fuſible body we call gold, be malleable or not, which experience, however it prove in that particular body we examine, makes us not certain that it is ſo in all or any other yellow, heavy, fuſible bodies, but that which we have tried; becauſe it is no conſequence, one way or other, from our complex idea. As far as our experience reaches, we may have certain knowledge, and no farther. It is not denied, but that a man, accuſtomed to rational and regular experiments, ſhall be able to ſee farther into the nature of bodies, and their unknown properties, than one that is a ſtranger to them; but this is only judgment and opinion, not knowledge and certainty. This makes our author ſuſpect that natural philoſophy is not capable of being made a ſcience from experiments and hiſtorical obſervations: we may draw advantages of eaſe and health, and thereby increaſe our ſtock of conveniencies for this life; but beyond this, he fears, our talents do not reach, and gueſſes that our faculties are not able to advance farther. See EXPERIMENTAL PHILOSOPHY.

The ways to enlarge our knowledge, as far as we are capable, ſeem to be theſe two: the firſt is, to get and ſettle in our minds, as far as we can, clear, diſtinct, and conſtant ideas of thoſe things we would conſider and know: for it being evident, that our knowledge cannot exceed our ideas; where they are either imperfect, confuſed, or obſcure, we cannot expect to have certain, perfect, or clear knowledge. The other is the act of finding out the intermediate ideas, which may ſhew us the agreement, or diſagreement, or repugnancy, of other ideas, which cannot be immediately compared. That theſe two, and not the relying on maxims, and drawing conſequences from ſome general propoſitions, are the right method of improving our knowledge in the ideas of other modes, beſides thoſe of quantity, the conſideration of mathematical knowledge will eaſily inform us; where we ſhall find, that he who has not clear and perfect ideas of thoſe angles or figures, of which he deſires to know any thing, is thereby utterly incapable of any knowledge about them.

Our knowledge, as in other things, ſo in this alſo, has ſo great a conformity with our ſight, that it is neither wholly neceſſary, nor wholly voluntary. Men, that have ſenſes, cannot chooſe but receive ſome ideas by them; and if they have memory, they cannot but retain ſome of them; and if they have any diſtinguiſhing faculty, cannot but perceive the agreement or diſagreement of ſome of them, one with another: as he that has eyes, if he will open them by day, cannot but ſee ſome objects, and perceive a difference in them, yet he may chooſe whether he will turn his eye towards an object, curiouſly ſurvey it, and obſerve accurately all that is viſible in it; but what he does ſee, he cannot ſee otherwiſe than he does: it depends not on his will to ſee that black which appears yellow. Juſt thus it is with our under-

understanding; all that is voluntary in our knowledge is the employing or with-holding any of our faculties from this or that ſort of objects, and a more or leſs accurate ſurvey of them; but they being employed, our will hath no power to determine the knowledge of the mind one way or other; that is done only by the objects themſelves, as far as they are clearly diſcovered.

KOLLOW, the name of a black kind of earth found in ſeveral parts of the kingdom.

KORAN, or ALCORAN. See ALCORAN.

KOS, in Jewiſh antiquity, a meaſure of capacity, containing about four cubic inches: this was the cup of bleſſing, out of which they drank when they gave thanks after ſolemn meals, like that of the paſſover.

KUTUCHTA, among the Calmuc-Tartars, the name of their high prieſt, or ſovereign pontiff; formerly only the deputy of the delai-lama, or high prieſt of the Tartars; but at preſent independent on him.

L.

L, A ſemi vowel, or liquid, making the eleventh letter of the alphabet.

It was derived from the old Hebrew Lamed, or Greek Lambda λ. It is ſounded by intercepting the breath between the top of the tongue and forepart of the palate, with the mouth open, and makes a ſweet ſound, with ſomething of an aſpiration; and therefore the Britons and Spaniards uſually doubled it, or added an *h* to it in the beginning of words, as in *llan*, or *lhan*, a temple, ſounding nearly like *ſl*, &c. In Engliſh words of one ſyllable it is doubled at the end, as *tell*, *bell*, *knell*, &c. but in words of more ſyllables than one it is ſingle at the end, as *evil*, *general*, *conſtitutional*, &c. It is placed after moſt of the conſonants in the beginning of words and ſyllables, as *black*, *glare*, *ad-le*, *ea-gle*, &c. but before none. Its ſound is clear in *Abel*, but obſcure in *able*, &c.

L, among the ancients, was a numeral letter, and is ſtill ſo in the Roman cyphering, and denotes fifty, according to the verſe,

Quinquies L denos numero deſignat habendos.

being half a C, which ſignifies a hundred, and was formerly written thus Ɛ. When a line was added at top L̄, it ſtood for 50,000.

LA, in muſic, the ſyllable by which Guido denoted the laſt ſound of each hexachord; if it begins in C, it anſwers to our A; if in G, to E; and if in F, to D.

LABARUM, in Roman antiquity, the ſtandard borne before the Roman emperors; being a rich purple ſtreamer, ſupported by a ſpear.

LABDANUM, or LADANUM, a reſinous juice, exuding upon the leaves of a ſmall ſhrub, which grows plentifully in Candy, and ſome of the other iſlands of the Archipelago. It is collected by lightly bruſhing the ſhrub, in the ſummer heats, with a kind of rake, having ſeveral ſtraps or thongs of leather fixed to it inſtead of teeth: the unctuous juice adheres to the thongs, and is afterwards ſcraped off with knives. The ſhrub is ſaid to be very plentiful alſo in Spain, but it does not appear that any labdanum is brought from thence.

Two ſorts of this reſin are met with in the ſhops. The beſt, though very rare, is in dark-coloured black maſſes, of the conſiſtence of a ſoft plaſter, growing ſtill ſofter on being handled: the other is in long rolls coiled up, much harder than the preceding, and not ſo dark. The firſt has commonly a ſmall, and the laſt a very large admixture of fine ſand, which in the labdanum examined by the French academy, amounted to three fourths of the maſs. It is ſcarcely indeed to be collected pure, independently of deſigned abuſes; the duſt blown on the plant by winds from the looſe ſands among which it grows, being retained by the tenacious juice.

Labdanum has been ſometimes exhibited as a reſinous corroborant and reſtringent, but principally employed in external applications and perfumes: the ſoft kind makes an uſeful ingredient in the cephalic and ſtomachic plaſters of the ſhops. This ſort has a very agreeable ſmell, and a lightly pungent bitteriſh taſte: the hard is much weaker; and the common means of purifying theſe kinds of ſubſtances, though they ſeparate the ſandy matter mixed with it, render it weaker ſtill.

LABEL, in heraldry, a fillet uſually placed in the middle, along the chief of the coat, without touching its extremities. Its breadth ought to be a ninth part of the chief. It is adorned with pendants; and when there are above three of theſe, the number muſt be ſpecified in blazoning.

This is a kind of addition to the arms of a ſecond brother, to diſtinguiſh him from the firſt, and is eſteemed the moſt honourable of all differences.

LABEL, in law, a narrow ſlip of parchment hanging from a deed, writ, or other writing, in order to hold the appending ſeal.

LABEL *of a Circumferentor*, a long thin braſs-ruler, with a ſight at one end, and a center-hole at the other; chiefly uſed with a tangent line, to take altitudes.

LABIA, the lips, in anatomy. See the article LIPS.

LABIAL LETTERS, thoſe pronounced chiefly by means of the lips. See LETTER.

LABIATED FLOWERS, monopetalous flowers, conſiſting of a narrow tube, with a wide mouth, divided into two or more lips. See BOTANY and FLOWER.

LABORATORY, or ELABORATORY. See ELABORATORY.

LABOUR, in general, denotes a cloſe application to work or buſineſs. Among ſeamen, a ſhip is ſaid to be in labour when ſhe rolls and tumbles very much, either a hull, under ſail, or at anchor. It is alſo ſpoke of a woman in travail, or child-birth. See DELIVERY.

LABOURING, in the marine, a violent rolling or pitching, ſo as to endanger the maſts and hull, by carrying away or ſpringing the former, and ſtraining the latter, ſo as to occaſion a leak or other diſaſter.

LABYRINTH, in anatomy, the internal cavity of the ear, ſo called from its ſinuoſities and windings. See the article EAR.

LABYRINTH, in gardening, a winding, mazy, and intricate turning to and fro, through a wilderneſs, or a wood.

The deſign of a labyrinth is, to cauſe an intricate and difficult labour to find out the center; and the aim is, to make the walks ſo intricate, that a perſon may loſe himſelf in them, and meet with as great a number of ſtops and diſappointments as is poſſible, they being the moſt valuable that are moſt intricate.

As to the contrivance of them, it will not be poſſible to give directions in words; there are ſeveral plans and deſigns in books of gardening: they are rarely met with but in great and noble gardens, as Hampton-Court, &c.

There are two ways of making them; the firſt is with ſingle hedges: this method has been practiſed in England. Theſe, indeed, may be beſt, where there is but a ſmall ſpot of ground to be allowed for the making them; but, where there is ground enough, the double are moſt eligible.

Double ones, or thoſe that are made with double hedges of a conſiderable thickneſs of wood between hedge and hedge, are approved as much better than ſingle ones; as

is the manner of making them in France, and other places; of all which, that of Verſailles is allowed by all to be the nobleſt of its kind in the world.

It is an error in labyrinths in making them too narrow, for by that means the hedges muſt be kept cloſe clipped: whereas if the walks be made wider, according to the foreign practice, they will not ſtand in need of it.

The walks are made with gravel, uſually ſet with hornbeams: the paliſades ought to be ten, twelve, or fourteen feet high: the hornbeam ſhould be kept cut, and the walks rolled. *Miller's Gard. Dict.*

LAC, Milk, among phyſicians, &c. See the article Milk.

LACCA, Lac, or Stick-Lac, improperly called gum-lac, in natural hiſtory, a concrete brittle ſubſtance, of a dark red colour; brought from the Eaſt-Indies incruſted on pieces of ſticks; internally divided into ſeveral cells; ſaid to be the reſinous juice of certain trees, collected by winged red inſects of the ant kind, impregnated with the tinging matter of the inſects, and by them depoſited either on the branches of the trees, or on ſticks faſtened in the earth for that purpoſe. In the cells are often obſerved ſmall red bodies, which appear to be the young inſects.

The tinging red animal matter of the ſtick-lac diſſolves both in water and in rectified ſpirit, and appears to be of the ſame general nature with that of cochineal; like which it is made dull by alkalies, and brighter by acids, and turned to a ſcarlet by a ſolution of tin.

Seed Lac.—If the lac be broken in ſmall pieces, or grains, and infuſed in warm water, till it ceaſes to give any tincture to the liquor; the remainder will appear of a tranſparent yellowiſh or browniſh colour, and, on raiſing the heat ſo as to make the water boil, melts and riſes to the ſurface, and is thence called ſhell-lac.

The grains, or the plates formed from them by liquefaction, thus robbed of the greateſt part of the animal tincture, ſeem to be of an intermediate nature between that of wax and reſins, or to partake of the nature of both: they crumble on chewing, and do not ſoften or ſtick together again: laid on a red-hot iron, they inſtantly catch fire, and quickly burn off, with a ſtrong and not diſagreeable ſmell: diſtilled, they yield, like wax, an acid ſpirit and a butyraceous oil: alkaline lixivia, and volatile alkaline ſpirits, diſſolve them into a purpliſh liquor: they diſſolve alſo, by the aſſiſtance of heat, in rectified ſpirit of wine, and communicate to it a yellowiſh or browniſh red colour, an agreeable ſmell, and a bitteriſh, ſub-aſtringent, not unpleaſant taſte. The lac in ſubſtance, whether entire, or freed from ſo much of its colouring matter as boiling water is capable of extracting, has no manifeſt taſte or ſmell.

A ſpirituous tincture of ſtick-lac has been ſometimes given as a mild reſtringent and corroborant, in female weakneſſes, and in rheumatic and ſcorbutic diſorders. But the principal medicinal uſe of this concrete is as a topical corroborant and antiſeptic, in laxities and ſcorbutic bleedings and exulcerations of the gums: ſome employ for this purpoſe a tincture of the lac in alum water; others, a tincture made in vinous ſpirits impregnated with the pungent antiſcorbutics: an ounce of the powdered lac, with half an ounce of the powdered myrrh, is by the college of Edinburgh directed to be digeſted in a ſand heat, for ſix days, in a pint and a half of ſpirit of ſcurvy-graſs.

Artificial Lacca, or Lake, in painting, a white earthy body, as cuttle-fiſh bone, the baſis of alum, or chalk, tinged with ſome crimſon vegetable dye, ſuch as is obtained from cochineal or Braſil-wood, diſſolved or taken up by means of ſome alkaline ſalt, and precipitated on the earth by the addition of ſome acid.

Lake is uſed in all kinds of painting, except enamel; but particularly in oil, where it ſupplies the place of carmine, which does not at all agree with that vehicle. It is valuable both for its brightneſs and crimſon teint; which make it uſeful for carnations to the portrait painters; for ſkies to the landſcape or ſhip painters; and for flowers to thoſe who paint ſtill life. Its tranſparency in oil renders it alſo of great ſervice in glazing, as it is called, over vermilion; and in painting ſcarlet draperies, and the red parts of the lips and its acquiring a dark hue, by this tranſparency, when uſed without the addition of any opake pigment, gives it an unrivalled excellence in the ſhades of red draperies, or other ſimilar caſes. Notwithſtanding theſe qualities, lake is not at preſent univerſally approved; nor without reaſon; for there is a defect which makes it to be frequently rejected, where its uſe can be avoided. This defect is the uncertainty of its ſtanding, when prepared in that manner which moſt conduces to its perfection in other reſpects: for though ſome parcels will hold their colour entirely well, yet others prepared in the ſame manner, as far as art can aſſure it, will fly in a degree that makes the uſe of it deſtructive to any painting: and if this defect be effectually remedied, as it may be by ſecuring the tinging particles by gums, from all attacks of the air; yet this is generally as the expence of the brightneſs and tranſparency; the earth, which is the baſis of the pigment, being locked up by the gums, and rendered incapable of being combined intimately with, or imbibing the oil. Beſides the perfections of lake, which it may have in common with other colours, there is yet another that relates only to itſelf, which is the inclining to the ſcarlet hue, that makes it more valuable for almoſt all the purpoſes to which it is applied; and where this quality, joined to the others, happens to be found in it, there is ſcarcely any limits to be ſet on its value with eminent painters of any kind.

Lake was moſt probably firſt made from the colour found in the grains of the ſtick-lac, from whence it ſeems to have taken its name; but it may be made from a great variety of ſubſtances which afford a crimſon tinge; though at preſent it is ſeldom prepared from any other than cochineal, ſcarlet rags, and Braſil-wood.

The beſt of what is commonly ſold is made from the colour extracted from ſcarlet rags, and depoſited on the cuttle-bone, which may be done in the following manner:

"Take a pound of the beſt pearl-aſhes, and having diſſolved them in two quarts of water, purify them by filtering through paper. Add then to this ſolution two more quarts of water; and having put in a pound of ſcarlet ſhreds, procured from the taylors, for they muſt be entirely clean, boil them in a pewter boiler made for that purpoſe, till the ſhreds appear to have wholly loſt their ſcarlet colour. Take them out of the ſolution, and preſs them well; dipping them after in water, and preſſing them again, that all the fluid they had imbibed may be got from them, which muſt be put back to the reſt. Take then another pound of the ſhreds, and repeat the like treatment of them in the ſame ſolution; as alſo a third and fourth pound. While this is doing, diſſolve a pound and half of cuttle-fiſh in a pound of ſtrong aqua-fortis, in a glaſs receiver, adding more of the bone, if it appear to produce any ebullition in the aqua-fortis; and having ſtrained off this ſolution through flannel, pour it into the other by degrees; obſerving whether it produce any effervеſcence on putting in the laſt quantity; which if it do in any great degree, more of the cuttle-fiſh bone muſt be diſſolved in aqua-fortis; and the ſolution very gradually added, till no ebullition appear to be raiſed by it in the mixture. If this be properly managed, the fluid will ſoon become clear and colourleſs, and the tinging particles extracted from the ſhreds, together with the cuttle-fiſh bone, will ſubſide to the bottom, and form a crimſon ſediment, which is the lake. The water muſt then be poured off; and two gallons of hard ſpring-water muſt be put to the lake, and well ſtirred about to mix them; which, being likewiſe poured off, after the lake has again ſettled to the bottom, muſt be replaced by another two gallons; and the ſame method muſt be repeated four or five times; but if hard water cannot be procured, or the lake appear too purple, half an ounce of alum ſhould be added to each quantity of water before it be uſed. When the lake is thus ſufficiently freed from the ſalts, it muſt have the water drained from it in a filter, covered with a linen cloth, which has been ſo worn as to have no knap or down remaining on its ſurface. After the lake has drawn to a proper dryneſs, it muſt be dropped, on clean boards, by means of ſticks of elder, mountain-aſh, or other hollow wood, cut into the form of pens, and ſuffered to dry; when the drops will appear in the form of little cones or pyramids."

If this lake be of a deeper colour than be deſired, the proportion of ſcarlet ſhreds may be diminiſhed; or if it be wanted yet deeper, they may be increaſed.

This lake, when the proceſs ſucceeds well, will be very bright; and will ſtand equally to any whatever: but it is not ſo tranſparent and fit for glazing as that where earth of alum is the baſis.

Lake may be prepared from cochineal in the following manner:

"Take two ounces of cochineal, and infuſe it in a gallon of ſtale but very clean urine for ſeveral days. Take alſo half an ounce of pearl-aſhes in a pint of water; filter both the ſolutions, and mix them. Make then a ſolution of cuttle-fiſh bone, as in the above proceſs; and to a pint of it add two ounces of alum diſſolved in half a pint of water. Put this mixture gradually to that of the urine and pearl-aſhes, as long as any ebullition appear to ariſe; and proceed as to the reſt according to the directions of the above proceſs."

This lake will be very fine if luckily managed, and will ſtand extremely well: it will alſo be very ſcarlet if the cochineal and annatto be good.

Preparation of beautiful LAKE *from Braſil-wood.*—"Take of Braſil-wood, not coloured in the grinding by the addition of pearl-aſhes, three pounds, and boil it an hour in a ſolution of three pounds of common ſalt in three gallons of water; and then filter the fluid through paper, while hot: prepare then a ſolution of five pounds of alum in three gallons of water; which add to the filtered ſolution of common ſalt, tinged with the colour. Make alſo a ſolution of three pounds of the beſt pearl-aſhes in a gallon and a half of water, and purify it by filtering: put this to the other gradually, till the whole of the colour appear to be precipitated, and leave the fluid clear and colourleſs; but if any appearance of purple be ſeen, add a freſh quantity of the ſolution of alum by degrees, till a ſcarlet hue be produced. The proportion of alum muſt however in this caſe be nicely adjuſted: for a ſmall exceſs will cauſe part of the tinging matter to be diſſolved again, which will appear by the fluid's being coloured; and in ſuch caſe, a ballance muſt again be made by the addition of a ſmall quantity of the ſolution of pearl-aſhes. When the fluid is thus rendered clear of colour, and the ſediment, being ſubſided, appears of a crimſon teint tending to ſcarlet, the directions in the firſt proceſs muſt be followed in every point."

This lake cannot be confided in for either painting in oil or water; but in varniſh, or for any other purpoſe, where it is defended from air, it is ſuperior to any other whatever, on account of its great brightneſs and tranſparency.

It may be rendered ſafe, however, with reſpect to ſtanding, if half a pound of ſeed-lac be added to the ſolution of pearl-aſhes; and diſſolved in it before its purification by the filter: but in this caſe, two pounds of the wood, and a proportionable quantity of the common ſalt and water muſt be uſed in the coloured ſolution. This will produce a lake that will ſtand well in either oil or water, and will ſometimes be extremely beautiful; but it is not ſo tranſparent in oil as without the ſeed-lac.

The lake with Brazil-wood may be made, alſo, with the addition of half an ounce of annatto to each pound of the wood: which will render it much more ſcarlet where it is ſo wanted. But the annatto muſt be diſſolved in the ſolution of pearl-aſhes, and not in that of the common ſalt along with wood.

The goodneſs of lake cannot be poſitively known but by the actual trial of it; which, with reſpect to its ſtanding, requires ſome time; but its other qualities may be more eaſily judged of.

With reſpect to the brightneſs, its merit may be eaſily proved by grinding a little of it, on a pallet or ſtone, with white lead and oil; where it may either be judged of by the memory of thoſe who are very converſant in the uſe of it, or by comparing it with a ſample of any other. In relation to the tranſparency, it is alſo eaſy to judge of it, by grinding a little, in the ſame manner, with oil only; where a muddineſs will be perceived, if the lake be in the leaſt opake: or a little of it may be put, in this ſtate, on the glaſs of a window; where its thickneſs or clearneſs will of courſe be apparent to the minuteſt degree. This indeed is the only method uſed in general by colourmen for deciding on all the qualities of lake; but it is very inconcluſive with regard to any but tranſparency.

There is another defect, with reſpect to ſome purpoſes, which is apt to be found in lake: it is the fatning in oil. This can only be known, by grinding ſome of it in the oil, and keeping it the proper time in bladders; when, if it be found to have this fault, it may be deemed utterly unfit for the uſe of colourmen. If nevertheleſs it have no other bad qualities, it is not at all the worſe for this, with regard to thoſe who have no occaſion to keep colours in bladders, but mix them as wanted on the pallet.

There is another kind of lake brought from China, which is extremely beautiful; but as it will not mix well with either water or oil, though it diſſolves entirely in ſpirit of wine, it is not of any uſe in our kinds of painting hitherto. This lake has, by ſome unaccountable blunder, got the name of ſafflower among thoſe who paint in water colours: and has, indeed, been ſo called by different perſons who have wrote on the uſe of water colours: but there is not the leaſt affinity betwixt it and the real ſafflower; which is the died flowers of the carthamus or baſtard ſaffron, and is a well known ſubſtance, as being a common dying drug.

Orange LAKE.—This lake is the tinging part of annatto precipitated together with earth of alum. It is of a very bright orange colour, and would work well with either oil or water, but cannot be depended upon, when uſed either of thoſe ways, for ſtanding long. It is, however, a very fine colour for varniſh painting, where the fear of flying is out of queſtion; and is alſo of an admirable good effect for putting under cryſtal for the imitation of the vinegar garnet; for which purpoſe it has been uſed with great ſucceſs.

The manner of preparing this lake is in the following manner.

"Take of the beſt annatto four ounces, and of pearl-aſhes one pound. Put them together into a gallon of water, and boil them half an hour; and then ſtrain the ſolution through paper.—Make, in the mean time, a ſolution of a pound and a half of alum, in another gallon of water: and mix it gradually with the ſolution of the pearl-aſhes and annatto; obſerving to ceaſe any further addition when the fluid becomes colourleſs, and no further ebullition enſues on the commixture. Treat the ſediment or precipitated matter, then, in the ſame manner as has been before directed for other kinds of lake; only this need not be formed into drops; but may be dried in ſquare bits or round lozenges."

LACHYRYMAL, in anatomy, an appellation given to ſeveral parts of the eye, from their ſerving to ſecrete the tears.

The lachrymal gland is ſituated in the orbit above the ſmaller angle, and its excretory ducts under the upper eye-lid: theſe are much more eaſily demonſtrated in the eye of an ox, than in a human one.

The lachrymal caruncle is ſituated in the larger angle, or canthus, ſerving to direct the tears to the two puncta lachrymalia; which are ſituated in the ſame angle, at the extremities of the tarſi or cartilages, and terminate in the lachrymal ſaccus, the naſal canal, and in the noſe itſelf. See the article EYE.

LACHRYMALIS FISTULA, in ſurgery and medicine. See FISTULA.

LACHRYMATORY, in antiquity, a veſſel wherein were collected the tears of a deceaſed perſon's friends, and preſerved along with the aſhes and urn.

LACONISM, λακονισμὸς, in matters of ſtyle, a ſhort, pithy obſervation or ſaying; ſo called from the Lacedæmonians, who were remarkable for the conciſeneſs of their diſcourſe: See STYLE.

LACTEA, or VIA LACTEA, the ſame with galaxy. See GALAXY.

LACTEAL VESSELS, in anatomy, long ſlender tubes for the conveyance of the chyle from the inteſtines to the common reſervatory. See the article CHYLE.

LACTIFEROUS PLANTS, in botany, ſuch plants as abound with a milky juice, as the lithymalus, ſonchus, and lettuce.

LACUNÆ, in anatomy, certain oſcula or orifices, proceeding from the glandulæ ſubſtratæ in the vagina,

and often ſo large as to admit a briſtle. Their uſe is to ſecrete a fluid for lubricating the vagina, and ſtimulating to venery.

LACUNAR, in architecture, an arched roof or ceiling, more eſpecially the planking or flooring above porticos and piazzas.

LADANUM, or LABDANUM, in pharmacy. See the article LABDANUM.

LADY's BEDSTRAW, a plant called by botaniſts gallium. See GALLIUM.

LADY's COMB, a plant otherwiſe called ſcandix. See the article SCANDIX,

LADY's FINGER, a ſpecies of vulneraria. See the article VULNERARIA.

LADY's MANTLE, the Engliſh name of alchimilla. See ALCHIMILIA.

LADY's SMOCK, the Engliſh name of cardamine. See CARDAMINE.

LADY's SLIPPER, the Engliſh name of the cypripedium. See CYPRIPEDIUM.

LADY's TRACES, a name by which ſome call orchis. See ORCHIS.

LADY-DAY, in law, the 25th of March, being the annunciation of the holy virgin. See the article ANNUNCIATION.

LAGOECIA, round-headed cummin, in botany, a genus of plants, the flower of which conſiſts of five petals, very ſhort, and bicornate: there is no pericarpium, the ſeed, which is ſingle, being contained in the cup.

This plant has neither the ſmell, appearance, or taſte of cummin; its ſmell being more like that of the carrot.

LAGOPHTHALMIA, in ſurgery, an everſion and gaping of the eye-lids, otherwiſe called ectropium. See the article ECTROPIUM.

LAIR, among ſportſmen, the place where the deer harbour by day. This term is alſo uſed to ſignify a place where cattle uſually reſt under ſome ſhelter: by which means the ground generally becomes enriched with their dung.

LAKE, a collection of waters contained in ſome cavity in an inland place, of a large extent, ſurrounded with land, and having no communication with the ocean.

Lakes may be divided into four kinds. 1. Such as neither receive nor ſend forth rivers. 2. Such as emit rivers, without receiving any. 3. Such as receive rivers, without emitting any. And, 4. Such as both receive and ſend forth rivers.

Of the firſt kind, ſome are temporary, and others perennial: moſt of thoſe that are temporary owe their origin to the rain, and the cavity or depreſſion of the place in which they are lodged: thus in India there are ſeveral ſuch lakes made by the induſtry of the natives, of which ſome are a mile, and ſome two in circuit; theſe are ſurrounded with a ſtone wall, and being filled in the rainy months, ſupply the inhabitants in dry ſeaſons, who live at a great diſtance from ſprings or rivers. There are alſo ſeveral of this kind formed by the inundations of the Nile and the Niger; and in Muſcovy, Finland, and Lapland, there are many lakes formed partly by the rains and partly by the melting of the ice and ſnow; but moſt of the perennial lakes, which neither receive nor emit rivers, probably owe their riſe to ſprings at the bottom, by which they are conſtantly ſupplied.

The ſecond kind of lakes, which emit, without receiving rivers, is very numerous. Many rivers flow from theſe as out of ciſterns; where their ſprings being ſituated low within a hollow place, firſt fill the cavity, and make it a lake, which not being capacious enough to hold all the water, it overflows and forms a river: of this kind is the Wolga, at the head of the river Wolga; the lake Odium, at the head of the Tanais; the Adac, from whence one branch of the river Tigris flows; the Ozero, or white lake in Muſcovy, is the ſource of the river Shackſna. The great lake Chaamay, which emits four very large rivers, which water the countries of Siam, Pegu, &c. viz. the Menau, the Aſa, the Caipoumo, and the Laquia, &c.

The third ſpecies of lakes, which receive rivers, but emit none, apparently owe their origin to thoſe rivers, which in their progreſs from their ſource, falling into ſome extenſive cavity, are collected together; and form a lake of ſuch dimenſions, as may loſe as much by exhalation, as it continually receives from theſe ſources: of this kind is that great lake improperly called the Caſpian ſea; the lake Aſphaltites, alſo called the Dead ſea; the lake of Geneva, and ſeveral others.

Of the fourth ſpecies, which both receive and emit rivers, we reckon three kinds, as the quantity they emit is greater, equal, or leſs than they receive. If it be greater, it is plain that they muſt be ſupplied by ſprings at the bottom; if leſs, the ſurplus of the water is probably ſpent in exhalations; and if it be equal, their ſprings juſt ſupply what is evaporated by the ſun.

Lakes are alſo divided into thoſe of freſh water, and thoſe of ſalt. Dr. Halley is of opinion, that all great perennial lakes are ſaline, either in a greater or leſs degree; and that this ſaltneſs encreaſes with time: and on this foundation he propoſes a method for determining the age of the world.

Large lakes anſwer the moſt valuable purpoſes in the northern regions, the warm vapours that ariſe from them moderating the pinching cold of thoſe climates; and what is ſtill a greater advantage, when they are placed in warmer climates at a great diſtance from the ſea, the exhalations raiſed from them by the ſun, cauſe the countries that border upon them to be refreſhed with frequent ſhowers, and conſequently prevent their being barren deſarts.

LAMA, the ſovereign pontiff or rather god of the Aſiatic Tartars, inhabiting the country of Barantola. The lama is not only adored by the inhabitants of the country, but alſo by the kings of Tartary, who ſend him rich preſents, and go in pilgrimage to pay him adoration, calling him *Lama-Congiu*, i. e. God the everlaſting father of heaven. He is never to be ſeen but in a ſecret place of his palace, amidſt a great number of lamps, ſitting croſs-legged upon a cuſhion, and adorned all over with gold and precious ſtones; where, at a diſtance, they proſtrate themſelves before him, it not being lawful for any to kiſs even his feet. He is called the great lama, or lama of lamas, that is, prieſt of prieſts. And to perſuade the people that he is immortal, the inferior prieſts, when he dies, ſubſtitute another in his ſtead, and ſo continue the cheat from generation to generation. Theſe prieſts perſuade the people, that the lama was raiſed from death many hundred years ago, that he has lived ever ſince, and will continue to live for ever.

LAMB, in zoology, the young of the ſheep-kind. See the article SHEEP.

LAMENTATIONS, a canonical book of the Old Teſtament, written by the prophet Jeremiah. The two firſt chapters of this book are employed in deſcribing the calamities of the ſiege of Jeruſalem. In the third, the author deplores the perſecutions he himſelf had ſuffered. The fourth turns upon the deſolation of the city and temple, and the misfortune of Zedekiah. The fifth chapter is a prayer for the Jews in their diſperſion and captivity; and at the end of all, he ſpeaks of the cruelty of the Edomites, who had inſulted Jeruſalem in her miſery. The four firſt chapters of the Lamentations are an abecedary, every verſe or couplet beginning with one of the letters of the Hebrew alphabet, in the alphabetical order. The ſubject is of the moſt moving kind, and the ſtile throughout lively, pathetic, and affecting. "Did we ever find, ſays Dr. South, ſorrow flowing forth in ſuch a natural prevailing pathos, as in the Lamentations of Jeremy? One would think, that every letter was wrote with a tear; that every word was the noiſe of a breaking heart; that the author was a man compacted of ſorrows, diſciplined to grief from his infancy; one who never breathed but in ſighs, nor ſpoke but in a groan."

LAMIÆ, in heathen mythology, a kind of dæmons, in the form of women, ſaid to have devoured children. See DÆMON.

LAMINÆ, in phyſiology, the thin plates whereof many ſubſtances conſiſt.

LAMIUM, dead nettle, in botany, a genus of plants, the flower of which conſiſts of one labiated and ringent petal: the ſeeds are four, triangular, and contained in the bottom of the cup.

The

The flowers of this plant are ſaid to be good in the fluor albus dyſentery, and ſcrophulous diſorders. The herb is aperient, emollient, and vulnerary.

LAMMAS-DAY, a feſtival celebrated on the firſt of Auguſt by the Romiſh church, in memory of St. Peter's impriſonment.

LAMP, λαμπας, a veſſel containing oil, with a lighted wick. See OIL, FLAME, FIRE, &c.

LAMPADARY, an officer in the ancient church of Conſtantinople, ſo called from his employment, which was to take care of the lamps, and to carry a taper before the emperor or patriarch when they went to church, or in proceſſion.

LAMPAS, LAMPERS, or LAMPRASS, among farriers, a ſwelling and inflammation in the roof of a horſe's mouth, ſo called becauſe it is cured by burning with a lamp or hot iron, in which operation great care ſhould be taken not to touch the bone.

LAMPERN, in ichthyology, a ſpecies of petromyzon, with a ſingle row of little teeth in the verge of the mouth, beſide the lower large ones. It grows to about a foot long, though moſt of thoſe uſually caught are under that ſtandard. See the article PETROMYZON.

LAMPREY, *Lampetra*, another ſpecies of petromyzon, with about twenty rows of teeth. It grows to two feet and an half, or more, in length. It is caught in ſome large rivers near the ſea, but is much leſs frequent than the former ſpecies.

LANCEOLATED LEAF, one reſembling a ſpear's point.

LANCET, a chirurgical inſtrument, ſharp pointed and two edged, chiefly uſed for opening veins in the operation of phlebotomy, or bleeding; alſo for laying open abſceſſes, tumors, &c.

LAND, in a limited ſenſe, denotes arable ground. See the articles EARTH, SOIL, HUSBANDRY.

It is alſo uſed for meadow-ground, paſture, wood, commons, &c. See the articles MEADOW, PASTURE, &c.

There are various methods of improving lands, as, 1. By incloſing and dividing the ſame into ſeveral fields, for paſture or tillage, which is one of the moſt principal ways of improvement; firſt, by aſcertaining to every man his juſt property, and thereby preventing a number of treſpaſſes and injuries, that lands in general are ſubjected to, beſide the diſadvantage of being obliged to keep the ſame ſeaſons with the other people who have land in the ſame field; ſo that the ſowing, fallowing, and tilling the ground, muſt be equally performed by all the land-holders; and, when there happens a ſlothful negligent perſon, who has land intermixed with others, it is one of the greateſt nuiſances imaginable. Secondly, it being of itſelf a very great improvement: for, where land is properly incloſed, and the hedge-rows planted with timber trees, &c. it preſerves the land warm, and defends and ſhelters it from the violent cold nipping winds, which in ſevere winters deſtroy much of the corn, pulſe, or whatever grows on the open field, or champain grounds. And where it is laid down for paſture, it yields much more graſs than the open fields, and the graſs will begin to grow much ſooner in the ſpring. The hedges and trees alſo afford ſhelter for the cattle from the cold winds in winter; as alſo ſhade for them in the great heats of ſummer. And theſe hedges afford the farmer plenty of fuel, as alſo plough-boot, cart-boot, &c. and, where they are carefully planted and preſerved, furniſh him with timber, and maſt for his ſwine: or, where the hedge-rows are planted with fruit-trees, there will be a ſupply of fruit for cyder, perry, &c. which, in moſt parts of England, are of no ſmall advantage to the huſbandman.

By this method of incloſing, there is alſo much more employment for the poor, and is therefore a good remedy againſt beggary; for in thoſe open countries, where there are great downs, commons, heaths, and waſtes, there is nothing but poverty and idleneſs to be ſeen amongſt the generality of their inhabitants. It is very obſervable of late years, how much advantage the incloſing of the land in Worceſterſhire, and ſome other counties at a diſtance from London, has been to the inhabitants; for, before this method was introduced amongſt them, the lands, for the moſt part, lay in commons, &c. upon which the poorer ſort of people built themſelves cottages with mud walls, where they contented themſelves with a cow or two, and ſome ſwine: and thoſe of them who were more induſtrious than the reſt, travelled to the neighbourhood of London every ſpring, where they were employed in the gardens and fields for the ſummer ſeaſon; and in autumn they returned to their native counties, where they lived, in winter, upon what money they had ſaved in ſummer. But, ſince they have converted their waſtes and commons into incloſures, there are but few of the inhabitants of thoſe counties who come to London for work, in compariſon to the numbers that formerly came; ſo that moſt of the labourers who come to London for employment, are either Welch, or inhabitants of ſome diſtant counties, where this improvement hath not as yet been introduced.

The advantages of incloſing land are now ſo generally known, that there is no occaſion for us to enumerate them here; ſince the improvements which have been made of late years, in ſeveral parts of England, and the increaſe of rent, that is every-where made by thoſe that incloſe, are ſufficient arguments to enforce the practice, and render it general; more eſpecially in the north, where it is much neglected; becauſe it would greatly ſhelter the lands, and render them much warmer than they now are.

In incloſing of land, there ſhould be regard had to the nature of the ſoil, and what it is intended for; becauſe corn land ſhould not be divided into ſmall parcels; for, beſides the loſs of ground in hedges, &c. the corn ſeldom thrives ſo well in ſmall incloſures, as in more open fields; eſpecially where the trees are large in the hedge-rows. The graſs alſo in paſtures is not ſo ſweet near hedges, or under the drip of trees, as in open expoſures; ſo that where the incloſures are made too ſmall, or the land is overplanted with trees, the herbage will not be near ſo good, nor in ſo great plenty, as in larger fields: therefore, before a perſon begins to incloſe, he ſhould well conſider how he may do it to the greateſt advantage: as, for inſtance, it is always neceſſary to have ſome ſmaller incloſures near the habitation, for the ſhelter of cattle, and the conveniency of ſhifting them from one field to another, as the ſeaſon of the year may require; and hereby the habitation, barns, ſtables, and outhouſes, will be better defended from ſtrong winds, which often do great damage to thoſe that are expoſed to their fury. Theſe ſmall incloſures may be of ſeveral dimenſions; ſome of them three, four, ſix, or eight acres in extent; but the larger diviſions for corn ſhould not contain leſs than twenty or thirty acres, or more, according to the ſize of the farm.

The uſual method of incloſing land is, with a ditch and bank ſet with quick. But in marſh land, where there is plenty of water, they content themſelves with only a ditch, by the ſides of which they uſually plant fallows or poplars, which, being quick of growth, in a few years, afford ſhade to the cattle; and when they are lopped, produce a conſiderable profit to their owners. See FENCE.

2. The draining of land is alſo another great improvement to it: for though paſtures and meadows, which are capable of being overflowed, produce a greater quantity of herbage than dry land; yet, where the wet lies too long upon the ground, the graſs will be ſour, and extremely coarſe; and where there is not care taken in time to drain this land, it will produce little graſs, and ſoon be over-run with ruſhes and flags, ſo as to be of ſmall value. See BOG and FEN.

As the draining of cold wet lands is a great improvement to them, ſo the floating or watering of dry looſe lands is not a leſs advantage to them. This may be eaſily effected where there are rivers, or reſervoirs of water, which are ſituated above the level of the ground deſigned to be floated, by under-ground drains, through which the water may be conveyed at proper ſeaſons, and let out on the ground: in order to this, there muſt be good ſluices made at the heads of the drains, ſo that the water may never get out, but at ſuch times as is required; for if this be not taken care of, the water, inſtead of improving the land, will greatly damage it.

But where the land lies ſo high, as that there is no water in the neighbourhood lying above its level, it will be more expenſive; becauſe, in ſuch caſe, the water muſt be raiſed, by machines, from reſervoirs or ſtreams which lie below it. The moſt common engine for this purpoſe is the Perſian wheel. See the article PERSIAN WHEEL.

Yet notwithſtanding the expence of raiſing the water, it has been found very advantageous, in many parts of England, to drown the lands; for the profit has many times more than doubled the charge.

The time for drowning of land is uſually from November to the end of April: but though this is the general practice, yet for many reaſons it is not to be approved of: the firſt is, that by the water lying continually on the ground in the winter, the roots of the finer ſorts of graſs are rotted and deſtroyed; and by letting on of the water, at the ſeaſon when the ſeeds of docks, and other bad weeds, which commonly grow by river-ſides, are falling, theſe ſeeds are carried upon the land, where they remain and grow, and fill the ground with bad weeds; which is commonly the caſe with moſt of the water meadows in England, the graſs in general being deſtroyed; ſo that ruſhes, docks, and other trumpery, make up the burden of theſe lands; but if theſe meadows were judiciouſly managed, and never floated till March or April, the quantity of ſweet good graſs would be thereby greatly increaſed, and the beautiful verdure of the meadows preſerved: but there is little hope of convincing thoſe perſons by arguments, who are ſo much wedded to their own prejudices, as to ſhut their eyes and ears againſt experiments or reaſon. Where the land is very hot and dry, and it lieth convenient to be watered at a ſmall expence, it ſhould be repeated every week in dry hot weather, which will prove a great advantage to the land. But, whenever this is done, there ſhould no cattle be admitted while it is wet; for they will poach, and ſpoil the turf.

3. Another great improvement of land is by burning of it; which, for ſour, heathy, and ruſhy land, be it either hot or cold, wet or dry, is a very great improvement; ſo that ſuch lands will, in two or three years after burning, yield more, excluſive of the charges, than the inheritance was worth before: but this is not to be practiſed on rich fertile land; for as the fire deſtroys the acid juice, which occaſions ſterility in the poor land, ſo it will in like manner conſume the good juices of the richer land, and thereby impoveriſh it; ſo that it hath been with great reaſon diſuſed in deep rich countries. See BURNING *of Land*.

4. It is alſo a very great improvement, where land is overgrown with broom, furz, &c. to ſtub them up by the roots; and when they are dry, lay them on heaps, and cover them with the parings of the earth, and burn them, and ſpread the aſhes over the ground. By this method vaſt tracts of land, which at preſent produce little or nothing to their owners, might be made good at a ſmall expence, ſo as to become good eſtates to the proprietors.

LANDSKIP, or LANDSCAPE, in painting, the view or proſpect of a country, extended as far as the eye will reach.

LANGUAGE, an aſſemblage of expreſſions among any people, whereby to communicate their thoughts to each other. And this chance or caprice has eſtabliſhed at firſt; ſo that uſage is the rule of a language, nor has reaſon any thing to do therein, unleſs to ſtudy or teach it, ſuch as it is. Here then commences grammar, which only furniſhes reflections, called rules, to which the manners of ſpeaking uſed in that language may be reduced.

Uſage may be divided into good and bad. The difference between theſe is, that the one is better eſtabliſhed than the other. In dead languages, that which makes the good uſage is the writings of the beſt authors in that language, and thoſe authors are allowed the beſt, who wrote when the ſtate was in its greateſt glory. Thus the age of Auguſtus being the moſt diſtinguiſhed period in the Roman hiſtory, we call that good Latin which is conformable to the manners of ſpeaking uſed by authors who wrote within fifty years before, or after the reign of that emperor. As to the living languages, the good uſage, or mode, is that which obtains amongſt the moſt eminent perſons, whether as to quality and authority, or as to learning, and the reputation of writing well.

There is found a conſtant reſemblance between the genius of each people, and the language they ſpeak. Thus the Greeks, a polite but voluptuous people, had a language perfectly ſuitable, full of delicacy and ſweetneſs. The Romans, who ſeemed only born to command, had a language noble, nervous, and auguſt; and their deſcendants, the Italians, are ſunk into ſoftneſs and effeminacy, which is as eaſily perceivable in their language, as in their manners. The language of the Spaniards is full of that haughtineſs which conſtitutes the diſtinguiſhing character of the people. The French, who have a world of vivacity, have a language that runs extremely briſk and lively. And the Engliſh, who are naturally blunt, thoughtful, and of few words, have a language exceeding ſhort, conciſe, and ſententious. See the articles GREEK, LATIN, ITALIAN, SPANISH, FRENCH, and ENGLISH.

The diverſity of languages is generally allowed to have taken its riſe from the confuſion at the Tower of Babel, both by Jews, Chriſtians, and Mahometans; but the manner in which this diverſity was effected, is ſtill in diſpute among the learned.

As to the point of antiquity and priority among languages, that too has been extremely controverted. The Egyptians and Phrygians diſputed concerning the antiquity of their languages: the Arabs diſpute the point of antiquity with the Jews; but theſe, jealous even to exceſs of the honour of their nation, poſitively inſiſt that the Hebrew tongue, ſuch as is found in the Holy Scriptures, is the primitive language, and that ſpoken by the firſt man; while others contend that the Hebrew, Chaldee, and Arabic, are only dialects of the original tongue: however that be, the Arabic is held to be the moſt copious of all languages. See the articles ARABIC, CHALDEE, HEBREW, EGYPTIAN, and PHRYGIAN, &c.

Languages are divided into 1. Original or mother tongues, as the Hebrew and Arabic in the eaſt; Kircher adds the Cophtic; the Teutonic and Sclavonic in the weſt. And Du Jon maintains the Gothic to be the mother of the Teutonic tongues, namely, thoſe ſpoken in the north; and ſome add the Biſcayan or Bas Briton, as the mother-tongue of the Celtæ or Gauls.

2. Derivative languages, which are thoſe formed out of a mixture of ſeveral others, as Latin, French, &c.

Learned or dead languages are thoſe which only ſubſiſt in books, and which muſt be learned by the rules of grammar, as the Greek, Hebrew, Syriac, and Chaldee.

Living languages are thoſe ſtill ſpoken in ſome country, or other, and which may be learned by converſation. The moſt popular among theſe are the French, Italian, Spaniſh, and Engliſh.

Speech is a privilege peculiar to man, and he is likewiſe furniſhed with organs proper for forming an articulate voice: hence it is eaſy to conceive men might form a ſettled and uniform language, by only affixing an idea to a word, and making others acquainted with it. And it is alſo eaſy to conceive that, the connexion betwixt moſt words and things being perfectly arbitrary, they may be changed at different places, at different times, and by different perſons. And it is not very unlikely that variety of capacities and inclinations, the different occaſions people have to expreſs themſelves, different terms of imagination, the eaſe people find in delivering themſelves rather one way than another, the forgetting old words, the many new things met with requiring new names, ſtrangers ſettling among natives, &c. it is not unlikely that theſe and many other cauſes ſhould occaſion an alteration in living languages.

When all mankind inhabited the ſame country, and kept up a commerce with each other, living through many ages, it is no great wonder that the common language was continued amongſt them, without any conſiderable alterations, till after the flood; ſince Noah himſelf was born not long after Adam's death, and a great many antediluvians living in Noah's time might have converſed with Adam and Eve ſome hundred years. Since all the world was then deſtroyed, except Noah and his family, the tongue ſpoken by this patriarch muſt be the only remaining language, and which might be eaſily handed down to his poſterity, as long as they dwelt in the ſame country

But when, before their parting, they attempted to build a city and tower, God confounded the language, inſomuch that, not being able to underſtand each other, they were forced to ſeparate and leave the building unfiniſhed.

LANGUED, in heraldry, is applied to ſuch animals whoſe tongues appear out of their mouths, being of a different colour from that of the body.

LANGUOR, a faintneſs or relaxation of the members, owing either to a want or decay of ſpirits.

LANIGEROUS, among herbaliſts, trees that bear ſuch a woolly or downy ſubſtance as is commonly contained in the catkins of the willow, &c.

The word is derived from the Latin, *lana*, wool, and *gero*, to bear.

LANIUS, the butcher-bird, in ornithology, a ſpecies of falcon, with black legs, a grey back, and variegated belly.

LANNAR, or LANNERET, the blue-legged falcon, with oblong black and white ſpots. It is a very beautiful bird, about the ſize of a common crow, very bold, and uſually kept for the diverſion of hawking.

LANTERN, or LANTHORN, a well known invention for ſhewing light in the night.

The word is derived from the French *lanterne*, which ſignifies the ſame thing.

Feaſt of LANTERNS, a Chineſe feſtival obſerved on the fifteenth day of the firſt month, when every Chineſe ſets out a large lanthorn illuminated with a great number of wax candles. Theſe lanthorns are more or leſs ſplendid, in proportion to the circumſtances of the owner: ſome of them are valued at ten thouſand crowns, on account of the decorations beſtowed on them; theſe are from twenty to thirty feet diameter, and ſerve as a kind of halls, in which they make ſumptuous entertainments.

Magic LANTERN, an optic machine, whereby little painted images are repreſented ſo much magnified, as to be accounted the effect of magic by the ignorant.

The contrivance is briefly this: ABCD (pl. LXXVII. *fig.* 5.) is a lantern, from whoſe ſide there proceeds a ſquare tube *bnklmc*, conſiſting of two parts; the outermoſt of which *nklm* ſlides over the other, ſo as that the whole tube may be lengthened or ſhortened by that means. In the end of the arm *nklm*, is fixed a convex glaſs *kl*; about *de*, there is a contrivance for admitting and placing an object, *de*, painted in dilute and tranſparent colours, on a plane thin glaſs; which object is there to be placed inverted. This is uſually ſome ludicrous or frightful repreſentation, the more to divert the ſpectators: *bhc* is a deep convex glaſs, placed in the other end of the tube, the only uſe of which is to caſt the light of the flame ſtrongly on the picture *de*, painted on the plane thin glaſs. Hence, if the object *de* be placed farther from the glaſs *kl* than its focus, it is manifeſt that the diſtinct image of the object will be projected by the glaſs *kl*, on the oppoſite white wall FH, at *fg*; and that in an erect poſture: ſo that, in effect, this appearance of the magic lantern is the ſame with that of the camera obſcura, or darkened room; ſince here the chamber EFGH is ſuppoſed quite dark, excepting the light in the lantern ABCD. See CAMERA OBSCURA.

And here we may obſerve, that if the tube *bnklmc* be contracted, and thereby the glaſs *kl* brought nearer the object *de*, the repreſentation *fg* ſhall be projected ſo much the larger, and ſo much the more diſtant from the glaſs *kl*; ſo that the ſmalleſt picture at *de* may be projected at *fg*, in any greater proportion required, within due limits: whence it is, that this lantern got the name of *lanterna megalographica*. On the other hand, protracting the tube will diminiſh the object. Inſtead of the convex glaſs to heighten the light, ſome prefer a concave ſpeculum, its focus being nearer than that of a lens; and in this focus they place the candle.

LANTERN, in architecture, a little dome raiſed over the roof of a building, to give light, and ſerve as a crowning to the fabric.

LANTERNISTS, a denomination aſſumed by the academicians of Thouloufe.

LANUGO, the ſoft down of plants, like that growing on the fruit of the peach-tree; whence ſuch plants are termed lanuginous.

LAPATHUM, the dock, in botany, a perennial plant bearing numerous imperfect flowers ſet in double cups; the outermoſt of which conſiſts of three ſmall green leaves, the inner of three larger reddiſh ones, which become a covering to a gloſſy triangular ſeed.

LAPATHUM *acutum folio plano*, ſharp-pointed wild dock, with long narrow acuminated leaves not curled about the edges, and the ſeed-covers indented and marked with little tubercles. The roots are of a browniſh colour on the outſide, and of a yellowiſh within, which grows deeper in drying.

The roots of the ſharp-pointed dock have a bitteriſh aſtringent taſte, and no remarkable ſmell: the roots of the other common wild docks are nearly of the ſame quality, equally diſcover their aſtringent matter both to the taſte and by ſtriking an inky blackneſs with a ſolution of chalybeate vitriol, and have been often ſubſtituted in our markets for thoſe of the ſharp-pointed kind; which laſt are generally, and, ſo far as can be judged from their taſte, juſtly, accounted the moſt efficacious. They are ſuppoſed to have an aperient and laxative, as well as an aſtringent and corroborating virtue; approaching in this reſpect to rhubarb, but differing widely in degree, their ſtypticity being greater, and their purgative quality, if really they have any purgative quality at all, far leſs. They ſtand recommended in habitual coſtiveneſs, obſtructions of the viſcera, ſcorbutic and cutaneous maladies: in which laſt intention, fomentations, cataplaſms, or unguents of the roots have been commonly joined to their internal uſe: in many caſes, the external application alone is ſaid to be ſufficient. A decoction of half an ounce or an ounce of the freſh roots, or of a dram or two of the dry roots, is commonly directed for a doſe.

LAPATHUM *aquaticum folio cubitali*, great wild water dock. See BARDANA.

LAPATHUM *rhabarbarum monachorum*, Monks rhubarb, garden patience; with large, broad, acuminated leaves; reddiſh, branched ſtalks; the leaves that cover the ſeeds unindented, and a tubercle on one of them: the root is of a yellow colour, with red veins, approaching in appearance to rhubarb.

This root is ſuppoſed to poſſeſs the virtues of rhubarb, in an inferior degree. It is obviouſly more aſtringent than rhubarb; but comes very far ſhort of it in purgative virtue, though given, as uſually directed, in double its doſe; nauſeating the ſtomach, without producing any conſiderable evacuation. It communicates a deep yellow tincture both to water and ſpirit.

LAPIDARY, an artificer who cuts precious ſtones. See the article GEM.

The art of cutting precious ſtones is of great antiquity. The French, though they fell into it but lately, have notwithſtanding carried this art to a very great perfection, but not in any degree ſuperior to the Engliſh. See DIAMOND.

LAPIDARY STYLE denotes the ſtyle proper for monumental or other inſcriptions; being a ſort of medium between proſe and verſe. The jejune and brilliant are equally to be avoided.

LAPIDESCENT, that which has the faculty of turning bodies to a ſtony nature.

LAPIS, in general, is uſed to denote a ſtone of any kind. See STONE.

LAPSA denotes a patron's neglect or omiſſion to preſent to a church within ſix months after it becomes vacant. When after a vacancy the patron does not preſent in ſix months, the ordinary has the next ſix months to collate to the benefice; and if he does not preſent within that time, the metropolitan has farther ſix months to do it in; and if he ſhould fail in doing it in his time, the next ſix months devolves to the crown.

LAQUEUS, in ſurgery, a kind of ligature ſo contrived, that when ſtretched by any weight, or the like, it draws up cloſe. Its uſe is to extend broken or disjointed bones, to keep them in their places when they are ſet, and to bind the parts cloſe together.

LARCENY, in law, a felonious carrying away another perſon's goods; and this, according to the value of the thing ſtolen, is either grand, or petit larceny; the firſt being ſtealing effects above the value of 1s. and the laſt ſuch as are either of that value, or under it: but

where two perſons together ſteal goods to the value of only 13d. it is grand larceny in both; and if one perſon at different times ſteal ſeveral different things from the ſame perſon, which amount upon the whole to above 12d. value, they may be joined in one indictment, and the offender found guilty of grand larceny; but this is very ſeldom practiſed; on the contrary, the jury, where the theft appears to be the firſt offence, frequently bring in their verdict, as they lawfully may, that the things are not above 10d. value, and by that means reduce the offence to petit larceny, though the offender may perhaps be indicted for ſtealing to the value of 30 or 40s. and upwards. The crime of grand larceny is puniſhable with death, and that of petit larceny, only with the corporal puniſhment of whipping, &c.

LARES, certain inferior deities among the ancient Romans, who were the guardians of houſes; they were alſo ſometimes taken for the guardians of ſtreets and ways, and Tibullus makes them the guardians of the fields.

LARGO, in the Italian muſic, a ſlow movement, one degree quicker than the grave, and two than the adagio. See the articles ADAGIO and GRAVE.

LARIX, the Larch tree, in botany, a genus of trees, whoſe leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote diſtances from the male flowers on the ſame tree: the male flowers are very like ſmall cones at their firſt appearance, but afterwards ſtretched out in length.

Theſe trees are propagated by ſeeds, which ſhould be ſown in the beginning of March, upon a bed of light ſoil, expoſed only to the morning ſun: or otherwiſe it may be ſown in pots or boxes of light earth, and placed near an hedge, where they may have the morning ſun only. The ſeed ſhould be covered about half an inch thick with fine light earth, and in very dry weather ſhould be gently refreſhed with water. In about ſix weeks, if your ſeeds were good, your plants will come up, at which time you ſhould careſully guard them againſt the rapacious birds, which would otherwiſe pull off the heads of the plants, as they thruſt themſelves out of the ground with their covers on them; and obſerve to refreſh them with water in dry weather, eſpecially if they are ſown in pots or boxes; as alſo to keep them clear from weeds, which, if ſuffered to grow among the young plants, will ſoon deſtroy them: nor ſhould they be too much expoſed to the ſun, or ſtrong winds; both which are very injurious to theſe plants, while they are young: but in October you ſhould, if they are in boxes or pots, remove them into a ſituation where they may be defended from ſharp winds, which are ſometimes hurtful to them, while young; but afterwards they will endure the ſevereſt weather of our climate.

Theſe trees are very proper for the ſides of barren hills, where few other ſorts will thrive ſo well; nor is this tree very delicate in its ſoil, but will grow much better on poor ſtrong ſtony land, than in rich ground: and, during the ſummer, they appear very beautiful; but in autumn they caſt their leaves, whereby ſome people have been deceived, by ſuppoſing them dead, and have deſtroyed them.

From the wounded bark of this tree exudes the pureſt Venice turpentine; and on the body and branches of it grows the agaric, which is a drug uſed in medicine: the wood is very durable, and, by ſome, reported to be very difficult to burn. But I do not know how this ſhould be, to a tree which abounds with turpentine; though it is ſaid alſo to be ſo ponderous as to ſink in water. It will poliſh exceeding well, and is by the architects abroad much coveted, both for houſes, and building of ſhips. Witſen, a Dutch writer upon naval architecture, mentions a ſhip to be long ſince found in the Numidian ſea, twelve fathoms under water, being chiefly built of this timber and cypreſs, both which woods were reduced to that hardneſs, as to reſiſt the ſharpeſt tools; nor was any part of it periſhed, though it had lain above a thouſand years ſubmerged. And it was upon tables of this wood that Raphael, and ſeveral of the greateſt artiſts, eterniſed their ſkill, before the uſe of canvas was introduced. *Miller's Gard. Dict.*

LARK, *Alauda*, in ornithology, a diſtinct genus of birds; the characters of which are theſe: the tongue, which is membranaceous and pointed, has a rim or margin round it; the beak is ſtraight, and pointed; the two chaps equal in ſize; and the claw of the hinder toe longer than any of the other toes.

To this genus belong, 1. The ſky-lark, with the long winged feathers, variegated with white and brown. 2. The tit lark, with a white line over the eyes. 3. The wood-lark, with the wings obliquely variegated with white. 4. The yellow-breaſted lark. 5. The ſnow-bird, or pied chaffinch, with the tail feathers black, except the three lateral ones, which are white.

LARK-SPUR, delphinium, in botany. See the article DELPHINIUM.

LARMIER, in architecture, a flat ſquare maſſive member of the corniche, between the cymatium and ovolo.

The word is derived from the French *larme*, a tear, as it cauſes the rain-water to fall at a diſtance from the wall drop by drop like tears. See CORNICHE.

LARUS, the gull, in ornithology, a genus of the anſeres order of birds, thus characterized: the beak is ſtraight all the way, except juſt at the point, where it turns down; add to this, that it is obtuſe, not denticulated along the ſides, and its lower chap gibbous or protuberant underneath.

LARYNGOTOMY, or BRONCHOTOMY. See the article BRONCHOTOMY.

LARYNX, in anatomy, forms the protuberance in the upper and anterior part of the neck, called pomum Adami: it is termed the head of the trachea arteria, being more prominent in men than in women. It principally conſiſts of five cartilages, as the cartilago thyroides, cricoides, two arytenoides, and the epiglottis; they are connected together by ligaments, and have muſcles, glands, and membranes belonging to them. The cartilago thyroides, which is the anterior and largeſt, is folded ſo as to have a longitudinal convexity on the foreſide, and two lateral portions which may be termed alæ.

The cricoid cartilage, which is the inferior and baſis of the reſt, reſembles a thick irregular ring, very broad on one ſide, and narrow on the other. It may be diſtinguiſhed into a baſis and top, into an interior, poſterior, and two lateral ſides. To the baſis the aſpera arteria is connected, ſo that the cricoides is the upper extremity of the trachea.

The cartilagines arytenoidææ are two ſmall, equal, and ſimilar cartilages, which joined together reſemble the ſpout of an ewer, and are ſituated on the top of the cricoides.

The epiglottis is an elaſtic cartilage, nearly like a purſlane leaf. It is ſituated above the anterior portion of the thyroides, and its lower extremity is tied by a ſhort, pretty broad, and very ſtrong ligament to the upper edge of that cartilage.

The cartilago thyroides is connected to the cricoides by ſeveral ſhort, ſtrong, ligaments, as alſo to the os hyoides by ſlender round ligaments, about a quarter of an inch in length.

In the middle of each of theſe ligaments we often meet with a ſmall cartilage of an oval figure, and much thicker than the ligaments. The thyroides is likewiſe connected to the os hyoides by a ſhort, broad, ſtrong ligament. It has alſo two ligaments which belong to the arytenoidææ.

The cricoides is tied to the lower part of the thyroides by a ſtrong ligament, and by the ligaments already mentioned to the inferior cornua of that cartilage. Its baſis is fixed to the firſt cartilaginous ring of the trachea arteria by a ligament exactly like thoſe by which the other rings are connected, and the membranous portion of the trachea is likewiſe fixed to the poſterior part of the baſis of the cricoides.

The cartilagines arytenoidææ are connected to the cricoides by ligaments which ſurround their articulations with the top of that cartilage. Anteriorly the baſis of each arytenoides is fixed to one end of a ligamentary cord, which by its other end is inſerted about the middle of the concave ſide of the anterior portion of the thyroides. At their inſertions in the thyroides theſe two ligaments touch each other; but a ſmall ſpace is left behind them; this is what is called the glottis.

Under theſe two ligamentary cords are two others, which run

run likewiſe from behind forward. The interſtice between the ſuperior and inferior cords on each ſide forms a tranſverſe fiſſure. Theſe two ſacculi are the ventricles of the ancients, and reſtored by Morgagni. They are principally formed by a continuation of the internal membrane of the larynx, and the inner ſurface of their bottom appears ſometimes glandulous.

On the anterior ſurface of the arytenoid cartilages there is a ſmall depreſſion filled by a glandulous body, which not only covers each arytenoid, but is alſo extended forward over the poſterior extremity of the neighbouring ligamentary cord. Theſe glands were diſcovered by Morgagni.

The epiglottis has alſo two lateral ligaments, by which it is connected to the arytenoides. It has alſo a membranous ligament, which ties it to the root of the tongue. This ligament is a duplicature of the membrane which covers the epiglottis. Laſtly, there are two lateral membranous ligaments fixed near the glandulous bodies called amygdalæ.

The epiglottis is not only perforated by regular holes, like the leaves of St. John's wort, but has alſo a great many irregular ſciſſures or breaks, which are ſo many lacunæ.

The larynx gives inſertion to ſeveral muſcles, which may be divided into common, proper, and collateral: the common are all thoſe which move the whole body of the larynx, and are four in number; two on each ſide, the ſterno-thyroidæi, and the thyro-hyoidæi, or hyo-thyroidæi.

The proper muſcles are thoſe inſerted wholly in the larynx, and which move the cartilages ſeparately. Theſe may be reduced to the following pairs, crico thyro-hyoidæi, crico-arytenoidæi laterales, crico-arytenoidæi poſteriores, thyro-arytenoidæi, arytenoidæi, thyro-epiglottici, aryteno-epiglottici, and hyo-epiglottici.

The collateral muſcles are thoſe which are inſerted by one portion in the larynx, without appearing to contribute to its motion; ſuch are the thyro-pharyngæi and crico-pharyngæi.

The larynx may alſo be moved by muſcles, which are not immediately inſerted therein; ſuch as the mylo-hyoidæi, genio-hyoidæi, ſtylo-hyoidæi, omo-hyoidæi, ſterno-hyoidæi, and eſpecially the digaſtrici of the lower jaw, by reaſon of their particular adheſion to the os hyoides. It is probable that theſe muſcles of the pharynx, which are inſerted in the baſis cranii, may move the larynx in ſome ſmall degree.

The larynx ſerves particularly to admit and let out the matter of reſpiration; and the ſolidity of its pieces hinders not only external objects, but alſo any hard thing, which we ſwallow, from diſordering this paſſage. The glottis, being a narrow ſlit, modifies the air we breathe, and as it is very eaſily dilated and contracted, it forms the different tones of the voice, by means of the different muſcles inſerted in the cartilagines arytenoidææ, to which the other muſcles, both proper and common, are aſſiſtants.

The whole larynx is alſo of uſe in deglutition, by means of its connection with the os hyoides, to which the digaſtric muſcles of the lower jaw adhere, which muſcles raiſe the larynx with the os hyoides every time we ſwallow.

The faculty of varying and changing the tone of the voice depends on the flexibility of the cartilages of the larynx, and decreaſes in proportion as we advance in age.

The muſculi ſterno-thyroidæi ſerve in general to pull down the thyroid cartilage, and the whole larynx with it: they may alſo aſſiſt the ſterno-hyoidæi, and compreſs the thyroid gland.

The thyro-hyoidæi may either draw up the larynx toward the os hyoides, or draw that bone downward toward the cartilago thyroides.

The crico-thyroidæi may either pull the cricoides obliquely backward, or thyroides obliquely forward.

Both the lateral and poſterior crico-arytenoidæi may ſeparate the arytenoid cartilages, and thereby dilate the glottis, the lateral muſcles ſeparating theſe cartilages obliquely forward, and at the ſame time relaxing the ſides of the glottis; but the poſterior muſcles ſeparate them obliquely backward, and at the ſame time ſtretch the ſides of the glottis; and when both muſcles act equally, they ſeparate the cartilages directly.

The thyro-arytenoidæi acting together, draw both the arytenoid cartilages forward, and ſo looſen the glottis, and render it capable of the ſmalleſt quaverings of the voice. They may alſo probably compreſs the lateral ſinuſes of the larynx, and alſo the arytenoid glands.

The arytenoidæi draw the arytenoid cartilages cloſe together, and preſs them againſt each other, and when in this ſituation, they may be inclined either forward by the thyro arytenoidæi, or backward by the crico-arytenoidæi poſteriores. By this means the glottis, when ſhut, may be either relaxed or tenſe; and in the laſt caſe, it is entirely ſhut, as when we hold in our breath in ſtraining.

The general uſe of the epiglottis is to cover the glottis like a penthouſe, thereby to hinder any thing from falling into it when we eat or drink, and for this purpoſe it is depreſſed. It alſo ſerves to hinder the air which we inſpire from ruſhing directly upon the glottis; but by ſplitting it, obliges it to enter in an oblique courſe. In deglutition the epiglottis may be ſufficiently depreſſed by the baſis of the tongue, and it may raiſe itſelf again by its own elaſticity without the aſſiſtance of its muſcles. The thyro-epiglottici and aryteno-epiglottici may ſerve to ſhut any lateral openings, that might remain, when the epiglottis is depreſſed by the baſis of the tongue; and the hyo-epiglottici may pull it a little forward in ſtrong reſpirations, as in ſighing or yawning. *Winſlow's Anat.*

LASERPITIUM, Laſer-wort, a genus of plants, the general corolla of which is uniform; the partial one conſiſts of five nearly equal petals, inflexo-cordated at the ends; there is no pericarpium; the fruit is oblong and ſeparable into two parts, and is ridged with eight longitudinal membranes; the ſeeds are two, very large, oblong, and ſemi-cylindric, plane on the one ſide, but on the other ornamented on the back and edges with four membranes.

LASSITUDE, *Laſſitudo*, in phyſic, a morbid ſenſation that comes on ſpontaneouſly without any previous motion, exerciſe, or labour. This is a frequent ſymptom in acute diſtempers. It ariſes either from an increaſe of bulk, a diminution of proper evacuation, or too great a conſumption of the fluid neceſſary to maintain the ſpring of the ſolids, or form a vitiated ſecretion of that juice.

The remedy in the firſt caſe is evacuation, and in the other a proper diet, or ſuch alterative medicines as influence ſuch a ſecretion.

LAST, in general, ſignifies the burden or load of a ſhip.

It ſignifies alſo a certain meaſure of fiſh, corn, wool, leather, &c. A laſt of cod-fiſh, white herrings, meal, and aſhes for ſope, is twelve barrels; of corn or rape-ſeed, ten quarters; of gun-powder, twenty-four barrels; of red-herrings, twenty cades; of hides, twelve dozen; of leather, twenty dickers; of pitch and tar, fourteen barrels; of wool, twelve ſacks; of ſtock-fiſh, one thouſand; and of flax or feathers, one thouſand and ſeven hundred pounds weight.

LAST, in the marſhes of Kent, is applied to a court held by the twenty four jurats, in which orders are given for the impoſing and levying of taxes for preſerving the ſaid marſhes.

LAST-HEIR, in law, he to whom lands come by eſcheat, for want of lawful heirs; who, in many caſes, is the lord of whom they are held, but in others the king.

LATERAL EQUATION, in algebra, a ſimple equation, whoſe root is only in one dimenſion.

LATERAN COUNCILS, thoſe councils held in the Baſilica of the Latin church at Rome. See the article COUNCIL.

There have been five councils held in this place, viz. in the years 1123, 1139, 1179, 1215, and 1513.

A LATERE, a term uſed to denote the qualifications of cardinals whom the pope ſends as legates into foreign courts, who are called legates a latere, as being aſſiſtants to his holineſs, and counſellors in ordinary; theſe are the moſt conſiderable of the three other legates, being ſuch as the pope commiſſions to take his place in councils,

and

and ſo called in regard that he never gives this office to any but his favourites and confidants, who are always *a latere*, at his ſide.

De LATERE, legates who are not cardinals, but yet are entruſted with an apoſtolical legation.

LATH, in building, a long, thin, and narrow ſlip of wood, nailed to the rafters of a roof or ceiling, in order to ſuſtain the covering.

Theſe are diſtinguiſhed into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, ſap laths, and deal laths; of which the two laſt are uſed for ceilings and partitions, and the firſt for tiling only.

Laths are alſo diſtinguiſhed according to their length, into five feet, four feet, and three feet laths, though the ſtatute allows but of two lengths, thoſe of five, and thoſe of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickneſs, but they are commonly leſs.

Of Cleaving LATHS.—The lath-cleavers having cut their timbers into lengths, they cleave each piece with wedges, into eight, twelve, or ſixteen, according to the ſize of their timber; theſe pieces are called bolts: this is done by the felt-grain, which is that grain which is ſeen to run round in rings at the end of a piece of a tree. Thus they are cut out for the breadth of the laths, and this work is called felting.—Afterwards they cleave the laths into their proper thickneſs with their chit, by the quarter grain, which is that which runs in ſtraight lines towards the pith. See the article GRAIN.

LATH-BRICKS, bricks much longer than ordinary, uſed inſtead of laths, for drying malt; for which purpoſe they are extremely proper, as not being liable to catch fire, and retaining the heat much longer than thoſe of wood; ſo that a very ſmall fire will ſerve, after they are once heated. See BRICK and MALT.

LATHE, an engine uſed in turning wood, ivory, and other materials. See plate LXXVII. *fig.* 6. It is compoſed of two legs or ſtyles, *a a*, which are commonly about two feet ten inches high, on the upper-part of which are faſtened two pieces of wood called cheeks, *b*, *b*, parallel to the horizon; between theſe are two pieces of wood, called puppets, *c*, *c*, made to ſlide between the cheeks, and to be fixed down at any point at pleaſure; near the upper end of one of theſe puppets is faſtened a ſtrong ſpike of tempered ſteel, *d*, and oppoſite to it, in the other, is an iron-ſcrew, *f*; by theſe the piece to be turned is ſuſtained, and is turned round by means of the ſtring *m*, put round it, and faſtened above to the pliable pole *l*, and underneath to the treddle or board, *i*, moved with the foot: there is alſo a piece of wood between the cheeks, called a reſt, *e*, whoſe office is to reſt the tool upon, that it may lie in a ſteady poſition while the workman uſes it.

When turners perform heavy work, which the pole and treddle will not command, they uſe inſtead of theſe a wheel (*fig.* 7.), which is turned about ſometimes with one, and ſometimes with two handles, according to the weight of the work; its ſtring hath both its ends neatly faſtened together, and this being fixed in a groove round the edge of the wheel, and after being croſſed, put round a groove in the work, it is eaſily turned round with a ſwift and regular motion. This is the moſt expeditious method of working; for the ſpringing up of the pole makes an intermiſſion in the turning of the work, but with the wheel it always turns the ſame way, ſo that the tool need never be taken off, unleſs it be to examine the work as it is doing.

Braziers, who turn pots, kettles, &c. have their lathe made in a different manner from that uſed by turners, as may be ſeen in *fig.* 8.

The puppets and reſts are much ſtronger than thoſe uſed by the turners: their edge-tools, which they call hooks, are alſo of a different ſhape from the chiſſels and other tools uſed by turners, as may be ſeen *ibid.* marked B 1, B 2, B 3, being bent backwards and forwards at the cutting end. And as the common turners work with a round ſtring made of gut, the braziers work with a flat leather-thong, which wrapping cloſe and tight about the rowler of their mandril, commands it with the greater eaſe, and turns it more forcibly about.

Small work in metal is turned in an iron-lathe, called a turn-bench, repreſented in *fig.* 9. When this is uſed, it is fixed in the chaps of a vice, and the work being fitted on a ſmall iron-axis, with a drill barrel fitted upon a ſquare ſhank near the end of it, the workman turns it round with a drill-bow, which he holds in his left hand, while he forms the moulding with a graver or other tool, which he holds in his right.

In turning oval or roſe-work, the common turner's lathe muſt be provided with the additional parts repreſented in *fig.* 10. which repreſents the whole machine with all its parts ready for working, A being the fore-puppet, with its apparatus; B, the hinder-puppet; C, a hollow axis, turned into a ſcrew-faſhion, to direct the weight D, by means of the nut E; and F, the ſupport of the tools, which may be raiſed or lowered at pleaſure.

LATHE, or LETH, as uſed in Kent and Suſſex, is part of a county, containing three or four hundreds.

LATHRÆA, great tooth-wort, in botany, a genus of plants, the corolla whereof conſiſts of a ſingle petal; the tube is longer than the cup; the limb is ringent and ventricoſe; the upper lip is concave, galeated, and broad, with a narrow crooked apex; the inferior one is leſs, and is reflex, obtuſe, and trifid; the fruit is a roundiſh elaſtic capſule, conſiſting of two valves, and containing only one cell; it is covered with a very large patent cup; the ſeeds are few and roundiſh.

LATHYRUS, chickling pea, in botany, a genus of plants, the corolla of which is papilionaceous; the fruit is a very long, cylindric or compreſſed, acuminated pod, conſiſting of two valves; the ſeeds are numerous, of a cylindric, globoſe, or ſomewhat angular figure.

LATIN, a dead language, firſt ſpoken in Latium, and afterwards at Rome; and ſtill uſed in the Romiſh church, and among many of the learned.

This language is principally derived from the Greek, and particularly from the Eolic dialect of that tongue, though it has a great number of words which it borrowed from the languages of the Etruſci, Oſci, and other antient people of Italy; and foreign commerce and wars, in courſe of time, added a great many more.

The Latin is a ſtrong nervous language, perfectly ſuitable to the character of the people who ſpoke it: we have ſtill works of every kind, admirably well written in the Latin, though there are vaſt numbers loſt. The Latin is more figurative than the Engliſh, more harmonious than the French, leſs copious than the Greek, leſs pompous than the Spaniſh, leſs delicate than the Italian, but cloſer and more nervous than any of them.

The Latin tongue was for a while confined almoſt wholly within the walls of Rome; nor would the Romans allow the common uſe of it to their neighbours, or to the nations they ſubdued: but, by degrees, they in time became ſenſible of the neceſſity of its being generally underſtood, for the conveniency of commerce; and accordingly uſed their endeavours that all the nations ſubject to their empire, ſhould be united by one common language, ſo that at length they impoſed the uſe of it, by a particular law for that purpoſe. After the tranſlation of the ſeat of the empire from Rome to Conſtantinople, the emperors of the eaſt being always deſirous of retaining the title of Roman emperors, appointed the Latin to be ſtill uſed; but at length neglecting the empire of the weſt, they abandoned all the care of the Latin tongue, and uſed the Greek. Charlemagne coming to the empire of the weſt, revived this language; but at length it gave way, and the French took place of the Latin.

The Latin, however, was prodigiouſly degenerated; for the incurſions of the Goths and Vandals brought an inundation of foreign words into it. But that was not all: when it once got into the courts of juſtice, it was ſtill worſe handled; till at laſt, being introduced amongſt the monks, it was debauched to that degree, that it was almoſt ſcandalous to uſe it.

In this condition it was found at the Reformation, where Lud. Vives, Eraſmus, &c. began to open the way for its recovery; ſince which time endeavours have been uſed to retrieve the pure Latinity of the Auguſtan age. See LANGUAGE.

LATISSIMUS, in anatomy, a large muſcle of the back, ſo called from its great breadth.

LATITAT, in law, a writ whereby all men in perſonal actions are called originally to the king's-bench: it is ſo called, as the defendant is ſuppoſed to lurk and cannot be found in the county of Middleſex to be taken by bill; but is gone to ſome other county, to the ſheriff of which this writ is directed, commanding him to apprehend the defendant there.

LATITUDE, in geography, the diſtance of any place from the equator, meaſured in degrees, minutes and ſeconds, upon the meridian of that place; and is either north or ſouth, according as the place is ſituated either on the north or ſouth ſide of the equator: Thus let *l* (plate LXXVIII. *fig.* 1.) repreſent London, *p* the north pole, *eq* the equator; then will *p l e s* be the meridian of London, and the arch *e l* the latitude of London, which being equal to 51° 32′, the latitude of London, is ſaid to be 51° 32′ north.

The latitude of a place is always equal to the elevation of the pole above the horizon: Thus *l e*, the latitude of London, is equal to the arch *p o*, the elevation of the pole *p* above the horizon *h o*.—For the method of finding the latitude of a place from obſervations of the ſun or ſtars, ſee OBSERVATION.

Complement of the LATITUDE, in geography, is the number of degrees, minutes, and ſeconds, which, added to the latitude, make it equal to 90°: Thus the complement of the latitude of London is 38° 28′; for 38° 28′ added to 51° 32′ is equal to 90°.

The complement of the latitude is always equal to the elevation of the equator above the horizon, or the angle intercepted between the plane of the equator and the plane of the horizon. Thus let *l* (plate LXXVIII. *fig.* 1.) be London, the latitude of London is the arch *e l*; the complement of the latitude is the arch *e h*, which meaſures the elevation of the equator *e q*, above the horizon *h o*, or the angle *e i h*, intercepted between the planes of the equator and horizon.

Circles of LATITUDE, in aſtronomy, are ſecondaries to the ecliptic, or circles drawn on the ſphere of the heaven, perpendicular to the ecliptic, and interſecting each other in the poles of the ecliptic.

LATITUDE *of a Star or Planet*, in aſtronomy, is its diſtance from the ecliptic in degrees, minutes, and ſeconds, meaſured on a circle of latitude drawn through that ſtar or planet, and may be either north or ſouth, as the object is ſituated either on the north or ſouth ſide of the ecliptic.

The ecliptic is drawn on the common celeſtial globes, by which we may ſee what conſtellations it paſſes through; there are alſo uſually ſix circles of latitude, which by their mutual interſections ſhew the poles of the ecliptic, as well as divide it into twelve equal parts, anſwerable to the numbers of months in a year. Plate LXXVIII. *fig.* 2. repreſents a celeſtial globe, where A G is the ecliptic, N the north, S the ſouth pole of the ecliptic, N A S, N B S, N C S, N D S, &c. are circles of latitude, or rather halves of them, which is as much as can be ſeen at one view upon the convex of the ſolid globe. The ſtar H is in ſo many degrees, minutes, and ſeconds of north latitude as the arch H A amounts to; the ſtar I is in ſouth latitude, the quantity whereof is meaſured by the arch I B.

From what has been ſaid it appears, that we muſt carefully diſtinguiſh the different notions of latitude, when applied to ſtars in the heaven, or places on the earth; that is, between latitude in aſtronomy, and latitude in geography; for in the heaven, or upon the celeſtial globe, it is the diſtance from the ecliptic; but upon the earth, or upon the terreſtrial globe, it is the diſtance from the equator. Indeed, ſometimes we conſider the diſtance of the heavenly bodies from the celeſtial equator; but this is called declination. See DECLINATION.

The latitude of a planet is either heliocentric, or geocentric.

Heliocentric LATITUDE *of a Planet* is the latitude it would appear in to a ſpectator placed in the ſun.

Geocentric LATITUDE *of a Planet* is the latitude it appears in to an inhabitant of the earth. See GEOCENTRIC *Latitude*.

To illuſtrate the difference between the heliocentric and geocentric latitude of a planet, let A B (plate LXXVIII. *fig.* 3.) be the orbit of the earth, C D the orbit of Mars, both viewed with the eye in their common ſection continued, whereby they appear ſtraight lines; let E and F be oppoſite points of the ecliptic: ſuppoſe Mars to be in his ſouth limit at C; if he were at that time viewed from S, the center of the ſun, he would appear in the ſphere of the heaven at the point H; his heliocentric latitude then is F H. But let Mars in C be viewed from the earth, and he will appear in different places, according as the earth is in different parts of her orbit; for if the earth be at B, a line drawn from B through C ſhews the apparent place of Mars to be at *g*, and his geocentric latitude is then F *g*; if the earth be at A, the apparent place of Mars will be in G, and his geocentric latitude F G; if the earth be in any other part of her orbit, as at the point I or K, it is eaſy to ſee, by a line drawn from either of thoſe points through Mars at C, that he will appear in different places in the ſphere of the heaven, and would be in different geocentric latitudes.

North aſcending LATITUDE *of the Moon*, when ſhe proceeds from the aſcending node towards her northern limit or greateſt elongation.

North deſcending LATITUDE is when the moon returns from her northern limit to the deſcending node.

South deſcending LATITUDE, when ſhe proceeds from the deſcending node to her ſouthern limit.

South aſcending LATITUDE, when ſhe returns from her ſouthern limit to her aſcending node.

And the ſame things hold good of the other planets.

LATITUDINARIAN, a perſon of moderation, with regard to religious opinions, who believes there is a latitude in the road to heaven, which may admit people of different perſuaſions.

LATTEN, a name formerly given to the plates of iron covered with tin, and now uſually called tin, of which our mugs, tea-canniſters, and the like, are made. The method of preparing thoſe plates of tin, as they are called, is as follows: plates of iron are prepared of a proper thinneſs; theſe are cut into ſquares fitted to receive the tinning; but it is not every kind of iron that will ſerve for this purpoſe, but only ſuch as is moſt diſtenſible, eaſily beating out to any degree of thinneſs when hot, and malleable even when cold, without danger of flying to pieces. Of this the Germans have large quantities, which they always ſelect for this purpoſe. This ſort of iron is firſt formed into ſquare bars of an inch in diameter; theſe they beat out a little into flatneſs, and then cut into pieces, which they call ſemelles, or ſoles. They fold theſe together, and having made them into parcels, containing forty pieces each, they beat them all at once with a hammer which weighs ſix or ſeven hundred weight. When they have done this, the principal part of the whole work is to prepare the leaves, now beat out to a proper thinneſs, ſo as that they ſhall readily receive the tin; for if there be but the ſmalleſt particle of duſt on them, or only the ſlighteſt ruſt in any part, the tin will never fix there.

This ſmoothing of the plates may be brought about by filing them, but that would be too expenſive, wherefore they do it by ſteeping them in acid waters. Thus preparing a great number at a time, they leave them in this liquor till the ſurface is a little preyed upon by it, and then they are ſcowered with ſand, which makes them very ſmooth and fine. By this means a woman cleans more plates in an hour, than the moſt expert workman can do in many days. Mr. Reaumur, to whom the world owes the diſcovery of this proceſs, mentions ſeveral waters, any one of which will ſucceed; but the Germans themſelves uſe nothing but common water, made eager with rye. This they make a great ſecret of, but the preparation is very eaſy. After they have ground the rye groſly, they leave it to ferment in common water for ſome time; and they are thus ſure of a ſharp and eager menſtruum, excellently fitted for their purpoſe. With this liquor they fill certain troughs, or tons, and into theſe they put ſeveral bundles of the plates of iron: and to make the liquor be more eager; and act the better on them, they keep it in ſtoves, where it has little air, and is kept warm with ſmall charcoal fires. The workmen go into theſe vaults once or twice a day, to turn the

plates, that they may be the better wrought upon, and put in others in their room. The more acid the liquor is, and the warmer the ſtove, the ſooner the plates are cleanſed: it requires, however, at leaſt two days to effect this, and frequently ſomething more.

This was the method which the German labourers, employed in the tin works in France, always made uſe of, in order to prepare the iron to receive the covering of tin; but the author, finding that this was a very laborious employ, and that the heat in the ſtoves was ſo great, that they could hardly bear it, propoſed ſome other methods in the place of this, which were attended with much leſs trouble, and as ſmall expence, if not leſs; and theſe, upon trial, were found to ſucceed equally well.

Having obſerved that the iron leaves, or plates, are covered with a ſmall layer of a ſort of ruſt, which they contract in the fire, and which the acid liquor took very little hold of; he judged it might be better to expoſe the plates to ruſt, in order to the cleanſing them eaſily of it; as ruſt is always accompanied with a ſort of fermentation, and the particles of ruſt, found on the ſurface of the iron, would be ſure to raiſe up every thing in their way. To this purpoſe he ſteeped the plates of iron in waters in which were ſeparately diſſolved alum, common ſalt, and ſal armoniac. Some other plates he did not ſteep in theſe liquors, but only juſt dipped them in, and then expoſed them to the air to ruſt. All theſe liquors, thus uſed, cauſed the iron to ruſt very freely, but the ſal armoniac beſt of all. After two days, during which every plate had been dipped into this menſtruum only twice or thrice, he ordered both theſe, and thoſe which had been left ſteeping during the ſame ſpace of time, to be ſcowered; and on comparing them together, it was found, that thoſe which had been dipped, and expoſed to the air, became much cleaner than thoſe which had been all the time ſteeped. The ruſt covered all the ſurface in the latter, without raiſing the ſcale; whereas, in the former, the ſurface was raiſed into bliſters of ruſt, which carried it wholly off with them. The diſſolvents, though very weak, are obſerved to produce the deſired effect, as well as ſtronger, which muſt be much dearer; but, among the latter, he prefers vinegar in France, which ſucceeds very well, and, being plentiful there, is very cheap. This operates ſo quick on the iron, that the plate need only be once dipped into it, and immediately taken out again, and ſet in a moiſt place, where it will ruſt in eight and forty hours. If the dipping is repeated three or four times, the ruſting will be ſtill more expeditious, and eſpecially if a ſmall quantity of ſal armoniac be diſſolved in the vinegar, about a pound to the puncheon. This will make a very efficacious menſtruum, the vinegar diſſolving iron very well, and the ſal armoniac ruſting it ſooner than any other ſalt. This however muſt be uſed very moderately, and the plate muſt be ſteeped in cold water afterwards, to take off any particle that might yet remain upon it, otherwiſe it would be ſubject to ruſt after it was tinned.

There are ſeveral other ways of making iron ruſt, as keeping it in a moiſt cellar, expoſing it to the dew, ſprinkling it with ſimple water, or, which is ſtill better, with water in which ſal armoniac has been diſſolved, ſeveral times a day; and in thoſe countries where the pyrites is common, the vitriolic waters, which partake of it, will do it very well. This water may be prepared at little or no expence, only by heaping up large quantities of the pyrites, and letting it moulder in the air, then putting it into common water, and making a lixivium of it.

The leaves of tin, when they are finiſhed, are always found to be more bright and gloſſy on one ſide than on the other, which is owing to the plates of iron having always ſeveral roughneſſes on one ſide, where it has been moſt expoſed to the hammer. Theſe roughneſſes are what are principally to be eaten down by the menſtruums; for which reaſon Mr. Reaumur greatly prefers ſprinkling, or wetting them, to ſteeping; becauſe, in ſteeping, as both ſides are equally expoſed to the force of the menſtruum, the ſmooth ſide muſt be conſequently eaten away too far, while the other is but eaten barely enough; this occaſions a loſs of the iron, which the author propoſes to ſave by ſprinkling, or ſimply wetting, as the bad ſide only might be ſubjected to the action of the menſtruum.

There are two other cautions, very neceſſary to be obſerved in this part of the work. The firſt is in the management of the plates, before they come to be prepared; which is, in the beating of them, to turn them continually about, ſo that all parts of every plate may be equally extended. And the other is, to plunge them into ſome ſoft clay, or fuller's earth, before they are heated, that they may not ſolder themſelves together.

Which ever method of ruſting the plates be uſed, it is always neceſſary to ſcower them with ſand, as ſoon as it is done; and, when they are thus cleaned, they muſt be immediately plunged into water, to prevent their ruſting again; and they are to be left in this water till the inſtant in which they are to be tinned, or, in the language of the workmen, blanched. The people employed in this part of the operation are called blanchers, and the others, who aſſiſt at the cleaning the plates, the ſealers. The blancher makes as great a ſecret of his art, as the ſealer does of his; and it was with great difficulty that Mr. Reaumur obtained it. The manner of doing it is this:

They flux the tin in a large iron crucible, which has the figure of an oblong pyramid with four faces, of which two oppoſite ones are leſs than the two others. The crucible is heated only from below, its upper part being luted with the furnace all round.

The crucible is always deeper than the plates, which are to be tinned, are long; they always put them in downright, and the tin ought to ſwim over them. To this purpoſe artificers of different trades prepare plates of different ſhapes, but Mr. Reaumur thinks them all exceptionable. But the Germans uſe no ſort of preparation of the iron, to make it receive the tin, more than the keeping it always ſteeped in water till the time; only, when the tin is melted in the crucible, they cover it with a layer of a ſort of ſuet which is uſually two inches thick, and the plate muſt paſs through this before it can come to the melted tin. The firſt uſe of this covering is to keep the tin from burning; as, if any part ſhould take fire, the ſuet would moiſten it, and reduce it to its primitive ſtate again. The blanchers ſay, this ſuet is a compounded matter. It is indeed of a black colour, but Mr. Reaumur ſuppoſes that to be only an artifice to make it a ſecret, and that it is only coloured with ſoot, or the ſmoke of a chimney; but he found it true ſo far, that the common unprepared ſuet was not ſufficient; for after ſeveral attempts, there was always ſomething wanting, to render the ſucceſs of the operation certain. The whole ſecret of blanching, therefore, was found to lie in the preparation of this ſuet; and this he at length diſcovered to conſiſt only in the firſt frying and burning it. This ſimple operation not only gives it the colour, but puts it into condition to give the iron a diſpoſition to be tinned, which it does ſupriſingly.

The melted tin muſt alſo have a certain degree of heat; for if it is not hot enough, it will not ſtick to the iron; and if it is too hot, it will cover it with too thin a coat, and the plates will have ſeveral colours, as red, blue, and purple; and upon the whole, will have a caſt of yellow. To prevent this, by knowing when the fire has a proper degree of heat, they might try with ſmall pieces of iron; but, in general, uſe teaches them to know the degree, and they put in the iron when the tin is at a different ſtandard of heat, according as they would give it a thicker or a thinner coat. Sometimes alſo they give the plates a double layer, as they would have them very thickly covered. This they do by dipping them into the tin, when very hot, the firſt time, and when leſs hot, the ſecond. The tin which is to give the ſecond coat, muſt be freſh covered with ſuet, and that with the common ſuet, not the prepared. *Phil. Tranſ.* N°. 406.

LATTEN-BRASS, plates of milled braſs, reduced to different thickneſs, according to the uſes it is intended for.

LATUS *Rectum*, in conics, the ſame with parameter. See PARAMETER.

LATUS TRANSVERSUM *of the Hyperbola*, a right line intercepted between the vertices of the two oppoſite ſections; or that part of the common axis, which is between the vertices of the upper and lower cones.

Such is the line E D (plate LXXVIII. *fig.* 4.) where alſo D *d* and E *e* may be the parameters or latus rectums be-

belonging to the two oppoſite ſections DLRO and OEOR.

To this latus tranſverſum anſwers the longeſt diameter in the ellipſis, which Apollonius calls the tranſverſe axis or diameter.

LATUS PRIMARIUM, a right line belonging to a conic ſection, drawn through the vertex of the ſection of the cone, and within it, as the line EE or DD. *fig.* 4.

LAVANDULA, lavender, in botany, a ſhrubby plant, with its leaves ſet in pairs, the ſtalks ſquare when young, and round when grown woody; producing on the tops of the branches, naked ſpikes of blue labiated flowers, of which the upper-lip is erect and cloven, the lower divided into three roundiſh ſegments.

LAVANDULA *Minor ſive ſpica*, lavender with oblong, very narrow, ſomewhat hoary, undivided leaves; a native of dry gravelly ſoils in the ſouthern parts of Europe, common in our gardens, and flowering in July.

The flowers of lavender have a fragrant ſmell, to moſt people agreeable, and a bitteriſh, warm, ſomewhat pungent taſte: the leaves are weaker, and leſs grateful. They are often employed as a perfume; and medicinally, as mild ſtimulants and corroborants, in vertigoes, palſies, tremors, and other debilities of the nervous ſyſtem, both internally and externally.

The flowers are ſometimes taken in the form of conſerve; into which they are reduced, by beating them, while freſh, with thrice their weight of double refined ſugar. Their fragrance is leſs injured by beating or bruiſing them, than moſt of the other odoriferous flowers, but is nevertheleſs conſiderably diminiſhed: the flavour of the leaves is of a much leſs deſtructible kind.

Water extracts by infuſion nearly all the virtue, both of the leaves and flowers. In diſtillation with water, the leaves yield a very ſmall portion of eſſential oil; the flowers a much larger, amounting, in their moſt perfect ſtate, when they are ready to fall off ſpontaneouſly, and the ſeeds begin to ſhew themſelves, to about one ounce from ſixty. The oil is of a bright yellowiſh colour, a very pungent taſte, and poſſeſſes, if carefully diſtilled, the fragrance of the lavender in perfection. It is given internally from one drop to five, and employed in external applications for ſtimulating paralytic limbs, and for deſtroying cutaneous inſects. The decoction, remaining after the diſtillation of the oil, is diſagreeably bitteriſh, and ſomewhat ſaline.

Rectified ſpirit extracts the virtue of lavender more completely than water. The ſpirit elevates alſo in diſtillation a conſiderable part of the odoriferous matter of the leaves, and greateſt part of that of the flowers; leaving, in the inſpiſſated extracts, a moderate pungency and bitteriſhneſs, with very little ſmell. A ſpirit prepared by pouring a gallon of proof ſpirit on a pound and a half of the freſh gathered flowers, and drawing off five pints by the heat of a water bath, is richly impregnated with the fragrance of the flowers. More compound ſpirits of this kind, in which other aromatics are joined to the lavender, have been diſtinguiſhed by the name of Engliſh or palſy drops. The college of London directs three pints of the ſimple ſpirit of lavender, and one pint of ſpirit of roſemary, to be digeſted on half an ounce of cinnamon, half an ounce of nutmegs, and three drams of red ſaunders, as a colouring ingredient: the college of Edinburgh orders a gallon and a half of rectified ſpirit of wine to be drawn over from three pounds of freſh lavender flowers, one pound of thoſe of roſemary, and three ounces of lemon peel; and afterwards three ounces of cinnamon, one of cloves, one of cubebs, and two of red ſaunders, to be macerated for three days in the diſtilled ſpirit. Theſe preparations are taken internally, on ſugar or in any convenient vehicle, from ten to an hundred drops, and uſed externally in embrocations, &c.

LAVANDULA *Major ſive vulgaris*, broad lavender, with longer, wider, and hoarier leaves, and much larger ſpikes, though ſmaller flowers; common in the ſouthern parts of Europe, but rare among us. The name ſpike is applied by foreign writers to this ſpecies, by ſome of ours to the firſt.

The broad-leaved lavender is ſtronger both in ſmell and taſte than the narrow, and yields in diſtillation almoſt thrice as much eſſential oil; but the flavour both of the oil and of the plant itſelf, is much leſs grateful: the oil is likewiſe of a much darker colour, inclining to green. Watery and ſpirituous extracts, made from the two ſorts of lavender, are very nearly alike; the difference ſeeming to reſide only in the volatile parts. *Lewis's Materia Medica.*

LAVATORY, or LAVOREDO, an appellation given to certain places in Chili and Peru, where gold is ſeparated from the earth by means of waſhing.

LAUDANUM, a preparation of opium. See the article OPIUM.

LAVENDER, the ſame with lavandula. See LAVANDULA.

LAVER, a ſacred utenſil in the temple of Jeruſalem, conſiſting of a baſon, whence they drew water by cocks.

LAUNCH, among ſailors, a ſort of boat uſed by the French, Italian, and Spaniſh ſhips; and is peculiar to thoſe which are employed in the Mediterranean trade, being better fitted for the ports of that ſea than a long-boat, than which it is generally much longer, and more flat-bottomed, and alſo ſharper before. See BOAT.

LAUNCHING *a Ship or Boat*, puſhing them into the water from an aſcent.

When the ſhips of the ancients, particularly thoſe of Greece, were launched, they were ornamented with garlands and flowers; the mariners alſo adorned with crowns, who ſhouted with loud acclamations and other expreſſions of mirth and joy; and being purified by a prieſt, with a lighted torch, and egg and brimſtone, or after ſome other manner, were conſecrated to the god whoſe image they bore.

In the launching of ſhips now-a-days, the ſame or ſimilar expreſſions of joy and feaſting are uſed, colours are diſplayed, and ſometimes muſic performed.

The greateſt ſhip ever launched in England was the Britannia of 100 guns, at Portſmouth; ſuch very large ſhips being uſually built in dry docks, and afterwards floated out by throwing open the flood-gates, and ſuffering the water to enter, when they are finiſhed.

LAUNDER, among miners, a place where they waſh the powdered ore.

LAUNIARD, a rope paſſing alternately through two dead-eyes, to draw them together. See the article DEAD-EYE.

In every dead-eye there are three holes, and two of theſe dead-eyes being faſtened in two ropes, oppoſite to each other, and the launiard paſſing alternately through the firſt hole in the upper, then the firſt hole in the lower, then the ſecond hole in the upper, proceeds till the whole purchaſe is compleated: after which the launiard, being well greaſed, is drawn extremely tight thro' all its parts, and draws the rope tight, to which the dead-eyes are faſtened: thus the ſhrouds of the maſts are drawn tight by fixing a dead-eye in the lower-end of each, with another directly underneath it, which is bolted to the ſhip's ſide by a ſhort chain; the launiard paſſing through theſe, is drawn tight by mechanical powers, and conſequently draws tight the ſhroud to which it is connected. See SHROUD.

LAUNIARD is alſo a ſmall cord or line by which any thing is held faſt, and can be occaſionally looſened, as the launiard of the buoy, the launiard of a port, &c.

LAURA, in church hiſtory, a name given to a collection of little cells, at ſome diſtance from each other, in which the hermits, in ancient times, lived together in a wilderneſs.

Theſe hermits did not live in community, but each monk provided for himſelf in his diſtinct cell. The moſt celebrated lauras mentioned in eccleſiaſtical hiſtory, were in Paleſtine; as the laura of St. Euthymius, at four or five leagues diſtance from Jeruſalem; the laura of St. Saba, near the brook Cedron; the laura of the Towers, near the river Jordan, &c.

LAUREATION, in the univerſities of Scotland, ſignifies the act of taking the degree of maſter of arts, which the ſtudents are permitted to do after four years ſtudy.

LAURENCE, or *Canons regular of St.* LAURENCE, a religious congregation in France, ſaid to have been founded by St. Benedict.

LAW denotes the command of ſome perſon or power, whoſe precept carries along with it the reaſon of obedience.

The word is derived from the Saxon *lah*, which ſignifies the ſame thing.

Thus the commands of God, a city, ſtate, or ſovereign power, are called their laws.

As all human actions depend upon the will, and the will of every ſingle man is different; therefore, to preſerve decency and order among mankind, there ſhould be ſome rule by which they are to be regulated; for otherwiſe it could not but give occaſion to vaſt confuſions. See the article GOVERNMENT.

This rule or law is nothing but a decree, by which the ſuperior obliges thoſe ſubject to him to accommodate their actions to the directions preſcribed therein. But that a law may exert its force in the minds of thoſe to whom it is promulgated, it is requiſite that the law-giver and the law be likewiſe known. The legiſlator of the laws of nature can be no other than the Creator of the univerſe. No man in civil ſociety can be ignorant who it is that has power over him; and of the laws he has notice given him, by a publication plainly and properly made, in which theſe two things ought to be aſcertained, that the author of the law is he who hath the ſupreme authority in the community, and that this or that is the true meaning of the law. The firſt is known, if it be promulged with his own mouth, under his own hand, or if it be done by proper delegates regularly admitted to that office: they muſt be thus judiciouſly executed, and, beſides that, contain nothing derogatory to the ſovereign power. As to the true ſenſe, after the greateſt plainneſs uſed by the promulgers, an explication is to be ſought of the legiſlator, or thoſe who are publicly appointed to give judgment according to law. See JUDGE.

Every perfect law has two parts; the one directing what is to be done, or omitted; the other declaring the puniſhment incurred, by neglecting to do what is commanded, or attempting what is prohibited. And herein all the force of law conſiſts. See PUNISHMENT.

Law may be divided, with reſpect to its authors, into divine and human: the former may be conſidered as twofold, to wit, natural or moral, and poſitive. Natural law is that which God has made known to mankind by the light of natural reaſon. Poſitive law is that which he has revealed by his prophets; ſuch were the laws delivered to the Jews relating to the divine worſhip and polity peculiar to that people.

Civil or human laws, conſidered with reſpect to the legiſlator's two offices, of judging and compelling, may be divided into diſtributive and penal. Diſtributive law is that which gives every ſubject what properly belongs to him, forbidding others to injure him either in his privileges or property: and penal law is that which determines or appoints what puniſhments ſhall be inflicted on thoſe who violate the diſtributive laws; it is mandatory, and ſpeaks only to the public officers, or magiſtrates.

The laws of any kingdom, or ſtate, firſt began with the ſtate itſelf; and if we conſider the world as one univerſal ſociety, or Europe as one great commonwealth, the law by which ſeparate nations are governed, with reſpect to treaties, alliances, the ſending embaſſadors, &c. is called jus gentium, or the law of nations: but when it is conſidered as made up of particular ſtates, the law which regulates the public order of each, is called jus publicum; and that law which determines the private rights of men, is called jus civile, or civil law. See CIVIL LAW.

The laws of England are at preſent divided into the common law, which is the moſt ancient law of the kingdom; the ſtatute-law, made by the king and both houſes of parliament; and particular cuſtoms in ſeveral parts of the kingdom: but our laws are more largely divided into the crown-law; the law and cuſtom of parliament; the common law; the ſtatute-law; reaſonable cuſtoms; the law of arms; eccleſiaſtical or canon-law; the civil law; the foreſt-law; the law of marque and repriſals; the law of merchants; martial-law, &c. See the articles COMMON-LAW, STATUTE, PARLIAMENT, &c.

Our laws have great reſpect to life, liberty, freehold, and inheritance: their uſe is to ſecure the continuance of thoſe bleſſings we enjoy; and they have therefore a particular relation to perſons and their eſtates, to crimes and miſdemeanors, &c. See the articles ESTATE, CRIME, &c.

LAW *of Arms*, is a law which gives precepts how to proclaim a war, to attack the enemy, and to puniſh offenders in the camp.

LAWS *of Nature or Motion*, in phyſics, are axioms or general rules of motion and reſt, obſerved by all natural bodies in their actions on one another; of theſe Sir Iſaac Newton has eſtabliſhed the three following.

1. All bodies continue their ſtate of reſt or uniform motion in a right line, till they are made to change that ſtate by ſome external force impreſſed upon them.

This law is no other than that univerſal property of bodies, called paſſiveneſs or inactivity; whereby they endeavour to continue the ſtate they are in, whatever it be. Thus a top only ceaſes to run round, on account of the reſiſtance it meets with from the air, and the friction of the plane whereon it moves. And a pendulum, when left to vibrate in vacuo, where there is nothing to ſtop it but the friction ariſing from the motion of the pin on which it is ſuſpended, continues to move much longer than one in the open air.

2. The change of motion, produced in any body, is always proportionable to the force whereby it is effected; and in the ſame direction wherein that force acts.

This is an immediate conſequence of this axiom, the effect is always proportionable to its cauſe. For inſtance, if a certain force produces a certain motion, a double force will produce double the motion; a triple force, triple the motion, &c. If a body is in motion, and has a new force impreſſed on it in the direction wherein it moves, it will receive an addition to its motion, proportional to the force impreſſed; but if the force acts contrary to its motion, the body will then loſe a proportional part of its motion: again, if the force is impreſſed obliquely, it will produce a new direction in the motion of the body, more or leſs different from the former, in proportion to its quantity and direction.

3. Re-action is always contrary and equal to action; or the actions of two bodies upon each other are equal, and in contrary directions.

Thus, ſuppoſe a ſtone or other load to be drawn by a horſe; the load re-acts upon the horſe, as much as the horſe acts upon the load; for the harneſs, which is ſtretched equally between them both ways, draws the horſe towards the ſtone, as much as it does the ſtone towards the horſe; and the progreſſive motion of the horſe is as much retarded by the load, as the motion of the load is promoted by the endeavours of the horſe. This will be better explained from the following inſtance; let a perſon ſitting in a boat draw another boat equally heavy towards him, they will both move towards each other with equal velocities: let the boat he ſits in be the lighteſt, and it will move the faſteſt; becauſe the action being equal on both ſides, the ſame quantity of motion will be given to each boat, that is, the leſſer will have the greater velocity.

We have a farther confirmation of this from attraction. Suppoſing two bodies attracting one another, but prevented from coming cloſe together by ſome other body placed between them: if their reſpective actions, by which they tend towards each other, were not equal on both ſides, then would the intermediate body be preſſed more one way than the other, and ſo all three would begin to move by themſelves the ſame way; but that three bodies ſhould be put in motion after this manner, when no external force acts upon them, is contrary to experience; conſequently, whatever different degrees of force any two bodies may be capable of exerting, their mutual actions on each other are always equal. This may be tried with a loadſtone and iron; which being put into proper veſſels, contiguous to one another, and made to float on the ſurface of water, will be an exact counterbalance to each other, and remain at reſt, whatever be the attractive power of the loadſtone, or the proportion of their reſpective magnitudes.

Theſe laws receive an abundant additional proof from hence, viz. that all the concluſions that are drawn from them

them in relation to the phænomena of bodies, how complicated ſoever their motions be, are always found to agree perfectly with obſervation. The truth of which ſufficiently appears in all parts of the Newtonian philoſophy.

LAWN, a large plain in a park, or adjoining to ſome grand ſeat. The moſt convenient ſituation is on the ſouth or ſouth-eaſt ſide of the houſe. If the lawn be a ſquare, three avenues may break out from three of the angles, and meet in the fourth angle oppoſite to the houſe: it may be bounded with walks or a ſingle row of lime-trees ſet at a good diſtance from one another. A circle is a good figure for a lawn, but muſt break off before it comes againſt the front. A triangle is a very proper figure, but ſhould be obtuſe or right-angled next the front.

Many perſons have preferred the lime-tree for this purpoſe, on account of their regular growth: but as the leaves of this tree often change their colour, and begin to fall very ſoon in the autumn, occaſioning a great litter in the garden; and from the end of July the trees make but an indifferent appearance; ſo they are not to be eſteemed for theſe plantations.

The elm, oak, beech, and chefnut, among the deciduous trees, are to be preferred to all others, as they keep their leaves late in autumn: and theſe are all of them large-growing trees; ſo are very proper for this purpoſe.

If there are ſome clumps of ever-green trees intermixed with the deciduous trees in this plantation, it will add to the beauty of it, eſpecially in the winter ſeaſon: the beſt ſorts for this purpoſe, are, the lord Weymouth's pine, the ſilver and ſpruce firs, which will grow faſt, and become large trees: and as the two latter ſorts always grow pyramidically, ſo they will have a good effect to the ſight, when properly diſpoſed with the deciduous trees: but as theſe generally feather out their branches near the ground, they ſhould be planted where they do not obſtruct the view of any diſtant objects.

But as moſt perſons who take pleaſure in beautifying their ſeats in the country, are in haſte for ſhade, they generally plant the trees too cloſe together, and often in ſuch a manner as to render it difficult, when the trees are advanced, to reduce their number, without injury to the deſign: therefore thoſe trees ſhould be firſt planted, which are deſigned to remain; and then there may be ſome few others planted for preſent ſhade, which may afterwards be taken away. When perſons who are beautifying their ſeats, meet with full grown trees on the ſpot, it is a great pleaſure; for theſe ſhould not be deſtroyed if they can poſſibly ſtand. *Miller's Gard. Dict.*

LAXATIVE MEDICINES are ſuch as regard either the belly or entire habit, and produce this effect by ſome ſoftening quality that takes away the tenſity of the fibres, and facilitates the paſſage of the contents in the internal tube.

LAY *Brothers*, among the Romaniſts, thoſe pious, but illiterate perſons, who devote themſeves, in ſome convent, to the ſervice of the religious.

LAY *Land*, or LEY *Land*, in huſbandry, fallow-ground, or ſuch as lies untilled. See LEYS.

LAY *Man*, one who follows a ſecular employment, or has not entered into holy orders.

LAY *Man*, among painters, a ſmall ſtatue, either of wax or wood, whoſe joints are ſo formed, that it may be put into any attitude or poſture. Its principal uſe is for adjuſting the drapery in cloathing of figures.

LAYERS, in gardening, are tender ſhoots or twigs of trees, laid or buried in the ground; till having ſtruck root, they are ſeparated from the parent-tree, and become diſtinct plants. The manner of performing this operation is as follows.

1. Take ſome of the boughs, and lay them into the ground about half a foot deep in fine freſh mould, leaving them with the end of the layer about a foot or a foot and a half out of the ground, and keep them moiſt during the ſummer-ſeaſon, and they will probably have taken, and be fit to remove, in autumn; and if they have not by that time taken root, they muſt lie longer.

2. Tie a piece of wire hard round the bark of the bough, at the place you intend to lay in the ground; and twiſt the ends of the wire, ſo that they may not untie; and prick the place above the wire, through the bark, with an awl in ſeveral places; and then lay it in the ground, as before directed.

3. Cut a ſlit upwards at a joint, as is practiſed in laying of carnations, which, by gardeners, is called tonguing the layers.

4. Twiſt the place which you deſign to lay in the ground like a withy, and lay it into the ground, as directed in the firſt way of laying.

5. Cut a place round about the bough, that is deſigned to be laid, an inch or two, at the place that is moſt convenient to lay into the ground, and manage it as is directed in the firſt method of laying.

The ſeaſon for laying hardy trees, that ſhed their leaves, is in October; but for ſuch as are tender, in March; for ever-greens, June or Auguſt are good ſeaſons.

Though layers may be laid at any time in the year, the before-mentioned ſeaſons are moſt proper, for the reaſons following; becauſe they have the whole winter and ſummer to prepare and draw root; for at thoſe times of the year the ſun has ſufficient power on the ſap of the tree to ſeed the leaf and bud, but has not power ſufficient to make a ſhoot.

And if that ſmall quantity of ſap that does ariſe be hindered, as it will by ſome of the preceding ways of laying, the leaves and buds will gently crave of the layer, and by that means will prepare the layer to take root, or put forth roots a little to maintain itſelf, finding it cannot have it from the mother-plant.

And therefore, becauſe it wants but little nouriſhment at that time of the year, it is better to lay layers of trees, or to ſet cuttings, than at other times, either in the winter, when the ſap ſtirs but little, or in the ſummer, when the ſap abounds, or in the ſpring, when it begins to riſe; becauſe it is then apt to come too ſuddenly to draw ſap from the layer, before the layer has drawn or prepared for root.

However, the ſpring or ſummer may do well for ſmall plants; becauſe ſuch plants, being but ſhort-lived, draw root the quicker.

If you would lay young trees from an high ſtandard, the boughs of which cannot be bent down to the ground, then you muſt make uſe of oſier-baskets, boxes, or pots, filled with fine ſifted mould, mixed with a little rotten willow-duſt, which will keep moiſture to aſſiſt the layer in taking root: this baſket, box, &c. muſt be ſet upon a poſt or treſſel, &c. and the bough muſt be laid according to either of the four firſt ways of laying; but too much head muſt not be left on, leſt that be injured by the wind, or by its own motion rub off the tender root; and the ſmaller the boughs are, the leſs way they ſhould be ſet out of the ground, and care muſt be taken to keep them clear from weeds.

The harder the wood is, the better will the young wood take root; but if the wood be ſoft, the older boughs will take root the beſt. *Miller's Gard. Dict.*

LAZARETTO, or LAZAR HOUSE, a public hoſpital for the reception of the ſick poor; and in ſome countries it is a detached edifice for perſons coming from places ſuſpected of the plague, to perform quarantine in.

LAZARUS, or LAZARO, a military order inſtituted at Jeruſalem by the Chriſtians of the Weſt, when maſters of the Holy Land, who received pilgrims under their care, and guarded them on the roads from the inſults of the Mahometans.

This order was inſtituted in the year 1119, and confirmed by a bull of pope Alexander IV. in 1255, who gave it the rule of St. Auguſtine.

LAZULA, or LAPIS LAZULI, a ſort of ſtone, from whence the celebrated colour called ultramarine is made.

This is one of the ores of copper, the baſis of which is a debaſed cryſtalline matter, coloured with the elegant and beautiful blue, which this matter gives in our experiment to all alkaline liquors. It is a very hard and compact ſtone, inſomuch as to come into the rank of thoſe that take a high poliſh, and are not liable to be ſcratched by accidents; and therefore is worked in a number of

different toys. It is found in detached lumps uſually of the ſize of a man's fiſt, often ſmaller, and ſometimes of four or five pounds weight: it is never covered with any coat or cruſt, but reſembles thoſe ſtones which have been waſhed off from whole ſtrata, and ſmoothed or rounded by accidents afterwards. It is of a naturally ſmooth and gloſſy ſurface; and its general colour is the elegant colour already mentioned; but this is variegated in a very beautiful manner with ſpots or clouds of white, and with veins of a fine ſhining gold colour. It has theſe variegations, in different degrees, in ſeveral maſſes, and in general moſt to be valued, as it has leaſt of them; for though very beautiful to the eye, they are foreign to all the uſes they are put to, except when it is cut as a gem. The white clouds or veins, for this matter is ſometimes, though more rarely, diſpoſed of in the laſt form, are uſually of a dead and opake hue; but ſometimes they are bright and pellucid as cryſtal; this laſt ſtate of them adds greatly to the beauty of the ſtone: the yellow ones are always bright and gloſſy; they have been ſuppoſed by many to be veins of gold, and the ſtone has been thence called a gold ore; but they are in reality only marcaſite. Sometimes that gold-like matter is not diſpoſed in veins, but in ſpots and ſtars, and in this caſe the ſtone is the ſapphire of the ancients; for they knew the gem we call the ſapphire by a very different name, calling it the ſky-blue beryl; and deſcribing what they meant by the word ſapphire to be a ſtone, opake, of a fine blue, and variegated with ſpots of a gold colour in form of ſtars. All the variations of this ſtone are ſubject, beſides, to other accidental foulneſſes, and are ſometimes debaſed to the ſtate of a mere common blue copper-colour.

The lapis lazuli is found in many parts of the world, but that of Aſia and Africa, in both which countries it is frequent, is vaſtly ſuperior, both in beauty and real value, to the Bohemian and German kind, which is brought too often to us in its place. It is to be choſen heavy, of a fine cloſe texture, and of a deep indigo blue colour, with a little white matter about it, and with as few of the ornamental gold coloured veins in it as poſſible, and ſuch as, when put in the fire, calcines without emitting any ſmell. Its virtues in medicine are thoſe of a very violent purgative and emetic, which are owing to the copper it contains. Chemical writers give us proceſſes for magiſteries, tinctures, and elixirs of lapis lazuli, but they are wholly out of uſe: whatever may be the preſent credit of the beautiful ſtone in medicine, the painters however are indebted to it for one of the nobleſt colours they are acquainted with; their ultramarine being only a calcination of this ſtone. The German lapis lazuli does not anſwer well in this proceſs, and diſcovers itſelf by its calcining eaſier than the African or Aſiatic, and turning greeniſh. The Oriental kind calcines to a finer blue than it naturally has, and retains the colour for ever. After calcining the ſtone in a clear fire of charcoal, they grind it to an impalpable powder on a porphyry, and then mixing it up in a paſte, compoſed of pitch, wax, and oil, they work it about with the hands; and, finally, kneading this in a veſſel of clear water, as the powder ſeparates from the viſcid matter, it ſinks to the bottom: when all that is perfectly fine in this is worked out, they let the water be drained off, and dry the powder for uſe. What remains embodied in the paſte, is afterwards ſeparated, and makes a worſe kind than the former, though even the very meaneſt ultramarine is a very beautiful colour.

LEAD, *Saturn*, in natural hiſtory, a pale or livid white metal, ſoon loſing its brightneſs in the air, and contracting a blackiſh or greyiſh aſh-colour; very ſoft and flexible; unelaſtic, and unſonorous; the heavieſt of all metallic bodies but gold, quickſilver, and platina: it is upwards of eleven times heavier than an equal bulk of water.

It melts in a very ſmall degree of fire, long before it grows red-hot: in a ſtrong red heat it emits viſible fumes. It loſes of its malleability in proportion as it is heated: by nimble agitation, when it is juſt ready to melt, or when returning from a fluid to a conſiſtent ſtate, it may be divided into ſmall grains, or powder. Granulated lead is commonly prepared, by pouring the melted metal into a wooden box rubbed on the inſide with chalk, and ſtrongly ſhaking it till it ſets or becomes ſolid; when large quantities are prepared, a wooden trough is made uſe of. It is formed into round granules or ſhot, by pouring the melted lead into cold water, through a perforated plate; a little orpiment being added to the metal infuſion; this improves its hardneſs, and makes it run more regularly into globules without drawing a tail.

Lead, when juſt become fluid, looks bright like quickſilver; but preſently contracts on the ſurface a variouſly coloured powdery pellicle. Some have ſuppoſed that this was an heterogeneous ſubſtance; and that the lead, by its ſeparation, became purer. But after this imaginary purification, it will ſtill, upon continuing the fire, exhibit a pellicle as at firſt: if this be taken off, or the metal ſtirred, ſo as to expoſe a freſh ſurface to the air, a new one will ariſe, till by degrees the whole quantity is changed into a duſky powder or calx, called plumbum uſtum. The injection of a little fat, charcoal powder, or other inflammable matters, prevents this change, and readily revives the calx into lead again, notwithſtanding Boerhaave's aſſertion that the calx of lead is very hard to reduce.

Calx of lead, expoſed to the fire in a furnace ſo contrived as that the flame may play upon its ſurface, becomes white, yellow, and at length of a bright red colour; hence the yellow lead or maſticot, and the red lead or minium of the painters. See the articles MASTICOT and MINIUM.

If lead be urged with a bright red heat, it changes by degrees into a yellow, flaſhy ſcoria, called litharge, of a paler or deeper colour, according to the degree of fire it has undergone. See LITHARGE.

All the calces and ſcoriæ of lead vitrify more eaſily than thoſe of any other metal: expoſed to a moderately ſtrong fire, they quickly run into a tranſparent yellow glaſs. This glaſs, in fuſion, powerfully diſſolves and vitrifies the more refractory metallic calces and earths; and unleſs ſaturated with theſe kinds of additions, corrodes and ſinks through the common crucible.

If gold or ſilver be mixed with lead, and expoſed to the fire, the lead ſcorifies, as it would by itſelf, and ariſes to the ſurface, ſo as to be raked off in the form of glaſs or litharge; at the ſame time carrying with it any imperfect metal that the gold or ſilver had been mixed with, but leaving thoſe perfect metals themſelves unhurt. Hence gold and ſilver are purified by means of lead from admixtures of the baſer metals; and hence lead is called by the chemiſts, *balneum ſolis & lunæ*, *lavacrum regis & reginæ*, *ſapa metallorum*, &c. The litharge met with in the ſhops is produced in thoſe works where gold and ſilver are thus purified; and contains the heterogeneous metals which the gold or ſilver had been mixed with.

Lead expoſed for ſome time to the ſteam of vinegar or other vegetable acids, is gradually corroded into a white calx, which is the ceruſs or white lead of the ſhops. See CERUSS.

Lead is employed for various mechanic uſes; as in thin ſheets for covering buildings, for pipes, pumps, ciſterns, ſtatues, ſhot, bullets, windows, for ſecuring iron bars in hard ſtones, for ſundry kinds of large veſſels for evaporation, and many other mechanic purpoſes. It has been obſerved that plants do not thrive ſo well in leaden, as in earthen and wooden veſſels. Its principal uſes in the chemical arts are, for promoting the vitrification of earthy and ſtony matters, in the making of glaſs, or in the ſmelting of ores, or in the glazing of earthen veſſels; for the refining of gold and ſilver; for the eliquation of ſilver from copper; for forming with oil the baſis of varniſhes and paints.

The effects of lead on the human body are dangerous: thoſe who are expoſed to its vapours in the fire, and even thoſe who grind its calces, minium, ceruſs, and litharge, for the painters, are ſubject to violent gripes and conſtipations of the bowels, contractions of the limbs, and other diſorders. Much more hurtful is the internal uſe of lead corroded or diſſolved by acids, as ceruſs, ſaccharum ſaturni, the ſolution in vinegar called acetum lithargyrii, or the tincture drawn from the ſaccharum, with ſpirit of wine, commonly called tinctura antiphthiſica. The ſaturnine preparations are applied externally with ſafety, as coolers, repellents, and deſiccatives: its calces, diſſolved in oils, form the baſis of moſt of the officinal plaſters.

Culinary veſſels, lined with a mixture of tin and lead, which is the uſual tinning, are apt to communicate to acid foods pernicious qualities, and require to be uſed with great precaution. In Holland, and perhaps in other places, it has been cuſtomary to correct the more offenſive expreſſed oils, as that of rape-ſeed, ſo as to ſubſtitute them to oil of olive or oil of almonds, by impregnating them with lead: this dangerous abuſe may be diſcovered by mixing a little of the ſuſpected oil with a ſolution of orpiment made in lime-water; on ſhaking them together, and ſuffering them to reſt, the oil, if it has any ſaturnine taint, will appear of an orange-red colour; if pure, of a pale yellowiſh. The ſame abuſe has been extended alſo to acid wines, which diſſolve ſo much lead as to acquire a ſweet taſte, and to become ſlow poiſons. The lead is readily diſcovered in theſe likewiſe, by the ſame ſulphureous ſolution, which changes the colour of wines impregnated with this metal to a browniſh red or blackiſh; lead, whether diſſolved, or in its metallic form, being conſtantly ſtained by ſulphureous liquors or vapours.

Lead is ſometimes found in the earth native, or in its metallic form, though very rarely pure. Its common ores are nearly of the colour of lead itſelf, and appear compoſed of cubes or parallelopipeds, ſometimes large and regular, ſometimes irregular and ſmall. There are lead ores alſo of a white, greyiſh, or greeniſh colour, and priſmatic figure; but theſe are rarely met with. The ores of ſilver, copper, and other metals, except tin and iron, have often a lead ore intermixed. The lead is extracted by fuſion in contact with the fuel; the furnace being ſufficiently heated with wood or charcoal, the powdered ore is thrown in by degrees, and freſh fuel and ore occaſionally ſupplied: the lead, revived by the inflammable matter of the coals, runs down into a baſon at the bottom of the furnace; from whence it is ladled out, and caſt into iron moulds, into large maſſes, called pigs of lead. All the common lead ores contain ſome ſilver; the ſteel-grained, and ſuch as are compoſed of ſmall cubes, have generally more ſilver than the compact and large diced ſorts: the white and green ſcarcely hold any. The ſilver is extracted, when its quantity is conſiderable enough to bear the expence of extracting it, by ſcorifying the lead upon a teſt; the whole being kept in fuſion on a hearth made of bone-aſh or other like materials, the lead partly vitrifies and ſinks into the hearth, and partly turns to litharge, which floats on the ſurface, and is raked or blown by bellows to one ſide; the ſilver at length remaining by itſelf. Lead almoſt always contains ſome portion of copper; and hence the ſilver obtained in this operation is ſcarcely ever free from ſome admixture of that metal.

LEAF, a part of a plant, commonly very thin, and flat, growing in the ſpring, and falling off in autumn.

Leaves are the ornament of the twigs, and conſiſt of a very glutinous matter, being furniſhed every where with veins and nerves. Their office is to ſubtilize the nouriſhing ſap, and convey it to the little buds; and likewiſe they ſerve to cover the flowers and fruits with their ſhade, and keep them from other inconveniences; they are to trees what hair is to the human body.

Dr. Grew obſerves, that the fibres of leaves conſiſt of two general kinds of veſſels, namely, for ſap and for air; and are ramified out of greater into leſs, as veins and arteries are in animals.

Mr. Frederick of Augſbourg, a celebrated gardener, took from the tree a leaf of the opuntia or Indian fig-tree; and ſetting it in the earth, it immediately took root, and produced bloſſoms and fruit.

The diſtinction of leaves, made by thoſe who have written on botany, are the following.

A ſimple leaf is that which is not divided to the middle.

A compound leaf is divided into ſeveral parts, each reſembling a ſimple leaf, as in liquorice, &c.

A digitated leaf is a compound leaf divided into ſeveral parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated leaf is a digitated leaf, conſiſting of three fingers, as the trefoil, &c.

A quinqueſoliated leaf is a digitated leaf, conſiſting of five fingers, as in the quinque folium.

A pennated leaf is a compound leaf divided into ſeveral parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is ſaid to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the caſſia; when the lobes are all nearly of the ſame form and bigneſs, it is called an uniform pennated leaf, as in the liquorice; when they are not ſo, it is ſaid to be difform, as in the agrimonia.

A winged leaf is, as it were, divided into ſeveral pennated leaves, as in the orobus, &c.

A ramoſe leaf is that which is ſtill farther divided than the winged leaf, as in the oſmund royal, female fern, &c.

An entire leaf or lobe is that which has no diviſion on its edges, as in the apple-tree, &c.

A ſinuated leaf is that which is cut about the edges into ſeveral long ſegments, as in common mallows.

A ſerrated leaf is that which is cut about the edges into ſeveral acute ſegments, reſembling the teeth of a ſaw, as in the nettle, &c.

A crenated leaf is that which is cut about the edges into ſeveral obtuſe ſegments, as in the betony, &c.

A laciniated or jagged leaf is that which is cut about the edges into ſeveral pretty deep portions, in an irregular manner, as in the horned poppy, &c.

Leaves are a part of a plant that is ordinarily very thin and flat, growing in the ſpring, and falling off at the autumn; though there are ſome plants without leaves, as the truffles and muſhrooms. *Miller's Gard. Dict.*

The leaves of plants are of the utmoſt conſequence to the life of the whole. Air evidently paſſes in at the leaves, and goes through the whole plant, and out again at the roots. If the leaves have no air, the whole plant will die, as is eaſily proved by the air-pump; but in theſe experiments, if the leaves be left on the outſide of the receiver, and parted by a hole cemented with wax, and have air, the plant will thrive, and grow, though its roots and ſtalk are kept in vacuo in water. The leaves of plants perform the neceſſary work of altering the water, received in at the roots, into the nature of the juices of the plant; and hence it is, that the life of the plants depends ſo immediately upon their leaves. The huſbandman often ſuffers for want of this knowledge. A crop of ſaintfoin is a very valuable thing, and its root being perennial, will yield him increaſe many years; but it is often deſtroyed at firſt, by ſuffering it to be indiſcreetly fed upon by the ſheep, which eating up all the leaves, the root remains without the means of a ſupply of air, and the whole periſhes.

Leaves being thus neceſſary to plants, nature has, in all perennial plants, provided a reverſionary ſtock of them. The leaves of theſe plants are always formed in autumn, though they are not unfolded till the following ſpring. They then open and increaſe gradually, in proportion to the motion of the ſap, and the quantity of pabulum it then receives to be circulated. Theſe leaves may alſo, though not wholly appearing out of the bud, be ſufficient for the extremely ſmall motion of life, which the ſap of perennial plants, that drop their leaves, has in winter. *Tull's Horſe-hoeing Huſbandry.*

The green colour of the leaves of plants is extracted by rectified ſpirit of wine, and by oils. The ſpirituous tinctures are generally of a fine deep green, even when the leaves themſelves are dull coloured or yellowiſh or hoary. The colour, however, ſeldom abides long even in the liquor, much leſs when the tinging matter is ſeparated in a ſolid form, and expoſed with a large ſurface to the air. The editor of the Wirtemberg Pharmacopæia obſerves, that the leaves of acanthus, brankenſine, or bears-breech, give a more durable green tincture to ſpirit, than thoſe of any other herb. Alkalies heighten the colour both of the tinctures and green juices: acids weaken, deſtroy, or change it to a browniſh. Lime-water improves both the colour and durability: by means of lime, not inelegant green lakes are procurable from the leaves of acanthus, lily of the valley, and ſeveral other plants.

There are very few herbs which communicate any ſhare of their green colour to water; perhaps none that give a green of any conſiderable deepneſs. It is ſaid, however, that the leaves of ſome plants give a green dye

to

to woollen, without the addition of any other colouring matter, particularly thoſe of the wild chewil or cow-weed, the common ragunt, and devils bit. The proceſs with this laſt, as deſcribed by Linnæus, is pretty remarkable. The peaſants, he informs us, in ſome of the Swediſh provinces, ſtratify the freſh leaves with woollen yarn, and boil them about as long as it is cuſtomary to boil fiſh. The whole is ſuffered to ſtand in the veſſel for a night: the wool, taken out in the morning, does not appear to have received any colour. The pot is again made hot, and the yarn hung over it, upon a ſtick, covered with an inverted diſh to confine the ſteam; for this ſteam is ſuppoſed to be eſſential to the colour. The yarn is afterwards wrung, the leaves taken out of the boiling liquor, a little freſh water added to the decoction, and the wool frequently dipped therein, till it appears ſufficiently coloured.

The leaves of many kinds of herbs and trees give a yellow dye to wool or woollen cloth that has been previouſly boiled with a ſolution of alum and tartar: weld in particular affords a fine yellow, and is commonly made uſe of for this purpoſe by the dyers, and cultivated in large quantity in ſome parts of England. There is no colour for which we have ſuch plenty of materials as for yellow. Mr. Hellot obſerves, in his *Art de Teindre*, that all leaves, barks, and roots, which on being chewed diſcover a ſlight aſtringency, as the leaves of the almond, peach, and pear-trees, aſh bark, eſpecially that taken off after the firſt riſing of the ſap in ſpring, the roots of wild patience, &c. yield durable yellows, more or leſs beautiful, according to the length of time that the boiling is continued, and the proportions of alum and tartar in the preparatory liquor; that a large quantity of alum makes theſe yellows approach to the elegant yellow of weld; that if the tartar is made to prevail, it inclines them to an orange; that if the roots, barks, or leaves, be too long boiled, the yellow proves tarniſhed, and acquires ſhades of brown; that for dyeing with weld, the beſt proportions of the ſalts are, four parts of alum, and one of tartar, to ſixteen of the wool; and that the wool, prepared with theſe, is to be boiled again with five or ſix times its quantity of weld; that for light ſhades, it is cuſtomary to diminiſh the alum, and omit the tartar; and that in this caſe, the colour is more ſlowly imbibed, and proves leſs durable.

LEAF, in architecture, the repreſentation of the leaf of the acanthus on the capital of the Corinthian and Compoſite orders. See the articles CORINTHIAN and COMPOSITE.

LEAF, in clocks and watches, an appellation given to the notches of their pinions. See the articles CLOCK and WATCH.

LEAGUE, a meaſure of length, containing more or leſs geometrical paces, according to the different uſages and cuſtoms of countries. A league at ſea, where it is chiefly uſed by us, being a land meaſure moſtly peculiar to the French and Germans, contains three thouſand geometrical paces, or three Engliſh miles.

The French league ſometimes contains the ſame meaſure, and in ſome parts of France it conſiſts of three thouſand five hundred paces: the mean or common league conſiſts of two thouſand four hundred paces, and the little league of two thouſand. The Spaniſh leagues are larger than the French, ſeventeen Spaniſh leagues making a degree, or twenty French leagues, or ſixty-nine and an half Engliſh ſtatute miles. The Dutch and German leagues contain each four geographical miles. The Perſian leagues are pretty near of the ſame extent with the Spaniſh; that is, they are equal to four Italian miles; which is pretty near to what Herodotus calls the length of the Perſian paraſang, which contained thirty ſtadia, eight whereof, according to Strabo, make a mile.

LEAGUE alſo denotes an alliance or confederacy between princes and ſtates for their mutual aid, either in attacking ſome common enemy, or in defending themſelves.

LEAK, among ſailors, a cranny or hole through which water enters into a ſhip either through her deck or ſides.

LEAKAGE, the ſtate of a veſſel that leaks, or lets water, or other liquid, ouze in or out.

Leakage, in commerce, is an allowance of 12 per cent. in the cuſtoms, allowed to importers of wines for the waſte and damage it is ſuppoſed to have received in the paſſage: an allowance of two barrels in twenty-two is alſo made to the brewers of ale and beer, by the exciſe-office.

LEAP, *Salto*, in muſic, is when the ſong does not proceed by conjoint degrees, as when between each note, there is an interval of a third, fourth, fifth, &c. See DEGREE and CONJOINT.

LEAP-YEAR, the ſame with biſſextile. See BISSEXTILE.

LEASE, in law, a demiſe or letting of lands, tenements, or hereditaments unto another for life, term of years, or at will, for a rent reſerved.

LEASE and RELEASE, as uſed in our law, ſignifies a certain inſtrument, in writing, for the conveyance of a right or intereſt in lands and tenements in fee to another.

LEASH, among ſportſmen, denotes three creatures of any kind; but chiefly greyhounds, foxes, bucks, and hares.

The term leaſh alſo ſignifies a line to hold in a hunting dog; and a ſmall long thong of leather, by which a falconer holds his hawk.

LEATHER, the ſkin of ſeveral kinds of beaſts dreſſed and prepared for the uſe of the various manufactures, whoſe buſineſs is to make them up. The butcher and others, who flay off their hides or ſkin, diſpoſe of them raw or ſalted to the tanner and tawer, and they to the ſhamoy, Morocco, and other kind of leather-dreſſers, who prepare them according to their reſpective arts, in order to diſpoſe of them among the curriers, glovers, harneſs-makers, coach-makers, ſaddlers, breeches-makers, gilt leather-makers, chair-makers, ſhoe-makers, book-binders, and all in any way concerned in the article of leather.

The three principal aſſortments of leather are tanned or tawed, and oil and alum-leather; and it may be affirmed, with great truth, that the ſkins of our own production, and thoſe imported from our colonies, when dreſſed in this kingdom, make the beſt leather in the world, and that therefore this is an article of great importance to the trade of the nation.

Though there is no little difference between the dreſſing of ſhamoy-leather, alum-leather, Hungary leather, Morocco leather, parchment, and tanning; yet the ſkins which paſs through the hands of theſe ſeveral workmen, ought to have been for the moſt part, at leaſt, waſhed clean from blood and impurities in a running water; ſet to drain, worked with the hands, or pounded with wooden peſtles in a vat; put into the pit, which is a hole lined either with wood, or with ſtone and mortar, filled with water in which quick-lime is diſſolved in order to looſen the hair, that it may be eaſily rubbed off without injuring the ſkin; drawn out, and ſet to drain on the edge of the pit; ſtretched on the leg or horſe, in order to have the hair ſcraped off with a blunt iron-knife, or wooden cylinder; the membranes on the fleſhy ſide, and the ſcabs or roughneſs on the grain-ſide, pared off with a ſharp-knife, and the ſkins rubbed with a whetſtone, to take off any particles of the lime, or any thing elſe that may occaſion hardneſs; thickened by different ſorts of powder, whereby they become greater in bulk, and ſo much lighter, as gradually to riſe to the ſurface of the water; ſtretched out green or half dried, and piled one over another; or put up ſeparate after they are dried, and hung out to air upon poles, lines, or any other way; which muſt be repeatedly done in the dreſſing of ſmall ſkins. This alternate tranſition from the liquid of the air into that of water, and from water into the air, with the aſſiſtance of lime, ſalts, and oils, opens the inmoſt fibres of the ſkin ſo effectually, as greatly to facilitate the introduction of ſubſtances proper for making them pliant without rendering them thinner.

The alum leather-dreſſer dreſſes all ſorts of white leather from the ox-hide to the lamb ſkin; for dreſſing the ſaddler's leather, he uſes bran, ſea-ſalt, and alum; and for that which the glover uſes, after the common preparatives, he firſt employs bran, and then with ſalt, alum, fine flower

flower and yolks of eggs mixed in hot water, he makes a ſort of pap, with which the ſkins are ſmeared in a trough.

The ſhamoy leather-dreſſer ſoaks in oil, not only the ſkins of the true ſhamoy, which is a wild goat, but likewiſe thoſe of all other goats. The tanner uſes the bark of young oaks ground in a tanning mill, in which he ſoaks the ſkins more or leſs, according to the different ſervices expected from them, their chief uſe being to remain firm and keep out water. In certain caſes, inſtead of tan, he uſes redon, which is chiefly uſed for tanning ram, ſheep-ſkins, and dreſſing Ruſſia leather. But for the different methods in which the tanner, currier, Ruſſia and Morocco leather-dreſſers proceed in finiſhing their ſkins, ſee the articles CURRYING, TANNING, &c.

LEAVEN, a piece of ſour dough, uſed to ferment and render light a much larger quantity of dough or paſte.

LECTICA, in Roman antiquity, a vehicle in which people were carried in a reclining poſture.

LECTISTERNIUM, a religious faſt or banquet of the ancient Romans. In times of public danger or calamity, or of thankſgiving for ſome happy event, the Republic ordered ſolemn feaſts to be made for the gods; and this ſolemnity was called lectiſternium, becauſe on this occaſion they ſpread tables, and placed beds around them, on which their heavenly gueſts were to lie and eat.

LECTURERS, in England, are an order of preachers in pariſh churches, diſtinct from the rector or vicar. They are choſen by the veſtry, or chief inhabitants of the pariſh, and are uſually the afternoon preachers.

LEDGER, the principal book wherein merchants enter their accounts. See BOOK-KEEPING.

LEE, in the ſea-language, that part of the hemiſphere to which the wind bloweth, in oppoſition to the weather or windward ſide. This expreſſion however is only uſed in a ſhip, when the wind croſſes the line of her courſe at a greater or leſs angle; and hence

Under the LEE implies farther to lee-ward, or farther from that part of the horizon from which the wind bloweth, as

Under the LEE *of the Shore*, i. e. at a ſhort diſtance from that ſhore which lies to the wind ward, or from the land where the wind blows from. This phraſe is commonly uſed to expreſs the ſituation of a ſhip or boat which may be anchored, or ſailing under the weather ſhore, where there is always ſmoother water and leſs danger of heavy ſeas than at a great diſtance from it.

The Land appears under our LEE, i. e. at ſome diſtance from a ſhip on that ſide to which the wind bloweth, as it thwarts her way: and hence

LEE-LARCHES, the ſudden roll which a ſhip makes to lee-ward in a high ſea, when a large wave ſtrikes her, and bears her weather-ſide violently up, which depreſſes the other in proportion.

LEE-SIDE is the ſide of a ſhip which is fartheſt from the wind, as oppoſed to the weather-ſide, which is neareſt to it.

Thus admit a ſhip to be ſailing north-ward with the wind at weſt, then her ſtar-board or right-ſide is the lee-ſide, and the lar-board or left, the weather-ſide.

To LEE-WARD, towards that part of the hemiſphere which lies under the lee, or to which the wind bloweth.

LEE-WARD-SHIP, a ſhip that, going cloſe hauled, loſes much ground, and deviates further to lee-ward from her courſe than common. See the article CLOSE-HAULED.

LEE-WAY is the angle that the rhumb-line, upon which the ſhip endeavours to ſail, makes with the rhumb upon which ſhe really ſails.

This is occaſioned by the force of the wind, or ſurge of the ſea, when ſhe lies to the windward, or is cloſe hauled; which cauſes her to fall off and glide ſide-ways from the point of the compaſs ſhe capes at. Thus, let NE/S W (plate LXXVIII. *fig.* 5.) repreſent the compaſs, and ſuppoſe a ſhip at C capes at, or endeavours to ſail upon the rhumb C *a*, but by the force of the wind and ſurge of the ſea ſhe is obliged to fall off, and make her way good upon the rhumb C *b*; then the angle *a* C *b* is the lee-way: and if that angle be equal to one point, the ſhip is ſaid to make one point lee-way; or if equal to two points, the ſhip is ſaid to make two points lee-way, &c.

The quantity of this angle is very uncertain; becauſe ſome ſhips, with the ſame quantity of ſail, and with the ſame gale, will make more lee-way than others; it depending much upon the mould and trim of the ſhip, and the quantity of water that ſhe draws. However, the common allowances made for lee-way, are theſe: 1. If the ſhip be cloſe hauled, has all her ſails ſet, the water ſmooth, and a moderate gale of wind, ſhe is ſuppoſed to make little or no lee-way. 2. If it blow ſo freſh, as to cauſe the ſmall ſails to be handed, it is uſual to allow one point. 3. If it blow ſo hard, that the tops muſt be cloſe reeſt, the ſhip then makes about two points lee-way. 4. If one topſail muſt be handed, it is common to allow two and three quarters or three points lee-way. 5. When both topſails muſt be handed, they allow about four points lee-way. 6. When it blows ſo hard as to occaſion the fore courſe to be handed, the allowance is between five and a half and ſix points. 7. When both main and fore courſes muſt be handed, then ſix, or ſix and a half points muſt be allowed for her lee-way. 8. When the mizzen is handed, and the ſhip is trying a hull, ſhe then makes her way good about one point before the beam, that is, about ſeven points lee-way.

Though theſe rules are ſuch as are generally uſed, yet as the lee-way depends much upon the mould and trim of the ſhip, we ſhall here give the method of aſcertaining it by obſervation: thus let the ſhip's wake be ſet by a compaſs in the poop, and the oppoſite rhumb is the true courſe made good by the ſhip; then the difference between this and the courſe given by the compaſs in the bittacle, is the lee-way required. If the ſhip be within ſight of land, the lee-way may be exactly found by obſerving a point on the land which continues to bear the ſame way; for the diſtance between the point of the compaſs it lies on, and the point the ſhip capes at, will be the lee-way. Thus, ſuppoſe a ſhip at C (*fig.* 6.) is lying up at N *b* W, towards A; but inſtead of keeping that courſe, ſhe is carried on the NNE line C B, and conſequently the point B continues to bear always the ſame way from the ſhip: here it is evident, that the angle A C B, or the diſtance between the N *b* W line that the ſhip capes at, and the NNE line that the ſhip really ſails upon, will be the lee-way. See the articles COMPASS, COURSE, JOURNAL, &c.

LEECH, *Hirudo*, in zoology. See the article HIRUDO.

LEECH *of a Sail*, the perpendicular or upward ſloping-edges of a ſquare, oblong, or triangular ſail: in a ſquare or oblong ſail, the leeches are thoſe which are perpendicular, as oppoſed to the upper-edge, which is called the head, and to the lower, which is called the foot of the ſail. In triangular ſails, when there are only three ſides, two of them are called the fore and after-leeches, and the third, which is the lower edge, the foot.

LEECH-LINE, one of the brails of the main-ſail and fore-ſail, or one of thoſe cords which draw them together in a lump, when they are to be furled or reefed. See the article BRAIL and FURL.

The leech-line is ſo called from its being faſtened to the ſail in or near the middle of the leech.

LEECH-ROPE, the rope to which the leech of the ſail is ſewed. See the article BOLT-ROPE.

LEEK, a garden plant, called by botaniſts porrum. See the article PORRUM.

Leeks are commonly ſown along with onions; the onions growing up firſt are pulled up, ſo that the leeks have room to grow to their full ſize.

LEER, in glaſs-making, a furnace where the veſſels are allowed to cool by degrees. See GLASS.

LEES, the more groſs and ponderous parts of liquors, which, being ſeparated by fermentation, fall to the bottom.

A ſpirit of a very agreeable flavour is obtained, by the common proceſs of diſtillation, from wine lees; and as this flavour depends greatly on the eſſential oil of the lees, care ſhould be taken to bring it over with the ſpirit. In order to this, the ſolid lees muſt be ſteeped in ſix or eight times their own weight of water, and well ſtirred at times, before they are put into the ſtill. See DISTILLATION.

LEET, *Leta*, a little court held within a manor, and called the king's court, on account that its authority to puniſh offences originally belonged to the crown, from whence it derived to inferior perſons. See COURT-LEET.

LEG, *Crus*, in anatomy, includes the whole of the lower extremities, from the os innominatum to the toes, being commonly divided into the thigh, leg, and foot. See THIGH and FOOT.

The leg conſiſts of three bones, the tibia, fibula, and rotula. The tibia is a long thick triangular bone, ſituated at the anterior internal part of the leg, and continued nearly in a ſtraight line from the thigh bone, to ſupport the whole ſuperior fabric.

Its ſuperior extremity is large, bulbous, and ſpongy, and is divided into two cavities by a rough protuberance, which again is hollow at its moſt prominent part, as well as at its poſterior and anterior baſes. The internal cavity is oblong and deep to receive the internal condyle of the thigh bone, while the external is more ſuperficial and round for the external condyle.

Below the anterior part of the upper extremity of the tibia, a conſiderable rough protuberance riſes, to which the ſtrong tendinous ligament of the rotula is fixed. On the internal ſide of this, a ſcabrous cavity is formed, where the ſeminervoſus, gracilus gracilis, and ſartorius muſcles are inſerted; whence ſurgeons know at what part the tibia ought to be ſawed. Below the external edge of this ſuperior extremity, a circular flat ſurface, covered, in a recent ſubject, with a cartilage, is found for the articulation of the fibula; between which and the anterior knob is a rough hollow, from which the tibialis anticus and extenſor digitorum longus ariſe. From the ſmooth flat ſurface, a ridge runs obliquely downwards and inwards, to give riſe to the tibialis poſticus. At the inſide of this ridge an oblique plain ſurface is left, where the muſculus poplitæus is inſerted, and part of the ſolæus has its origin. Some way above the middle of the bone, the internal angle terminates, and the bone is made round and rough by the muſculus ſolæus. Near this, the paſſage of the medullary veſſels is ſeen ſlanting obliquely downwards in the poſterior plain ſurface.

The inferior extremity of the tibia is hollow, but ſo that a ſmall protuberance riſes in the middle. The internal ſide of this cavity, which is ſmooth, and in a recent ſubject is covered with a cartilage, is produced into a conſiderable proceſs, called malleolus internus, whoſe extremity is divided by a notch, and from it ligaments are ſent out to the foot. This internal malleolus is ſituated more forwards than the internal condyle of the ſuperior extremity of this bone, which is neceſſary to be remarked in reducing a fracture of the leg. The external ſide of this extremity has a rough ſemilunar cavity for receiving the inferior extremity of the fibula. The poſterior ſide has two lateral grooves and a ſmall middle protuberance. In the internal depreſſion the tendon of the muſculus tibialis poſticus is lodged; and in the external, the tendon of the flexor longus digitorum plays. From the middle protuberance ligamentary ſheaths go out for tying theſe tendons.

The fibula is the ſmall long bone, on the outſide of the leg, oppoſite to the external angle of the tibia, being irregularly triangular.

The ſuperior head of the fibula has a ſuperficial circular cavity on its inſide, which, in a recent ſubject, is covered with a cartilage, but ſo cloſely connected to the tibia, as to allow only a ſmall motion backwards and forwards. This head is protuberant and rough on its outſide, where the biceps is inſerted; and below its internal poſterior ſide, there is a tubercle which gives riſe to the ſtrong tendinous part of the ſolæus.

The external ſurface of this bone is depreſſed obliquely from above downwards and backwards by the two peronæi; and the anterior ſurface bears the prints of the extenſor digitorum longus, nonus, Veſalii, and extenſor pollicis longus. From the internal angle the ſtrong ligament is produced to be continued to the tibia, for the connection of theſe two bones, and origin of ſeveral muſcles. The poſterior ſurface is the ſmootheſt: in the middle of it the paſſage of the medullary veſſels is ſeen ſlanting downwards. The direction of theſe veſſels has been particularly deſcribed, leſt in any chirurgical operation they be opened too near the bone to occaſion an obſtinate hæmorrhage.

The inferior extremity of the fibula is extended into a ſpongy oblong head, on the inſide of which is a convex, irregular ſurface, that is received by the external hollow of the tibia, and ſo firmly joined thereto by a thin cartilage and ſtrong ligaments, that it ſcarce can move. Below this, the extremity of the fibula is ſtretched out into a coronoid proceſs, ſmooth, and covered with a cartilage, and contiguous to the outſide of the firſt bone of the foot, to ſecure the articulation on that ſide. This proceſs is called malleolus externus. This proceſs being farther back than the internal malleolus, and in an oblique direction, we turn the fore-part of the foot outwards. At its inferior internal part, there is a ſpongy cavity for mucilaginous glands; from its points ligaments go out to the foot, and on its back part there is a ſinuoſity made by the tendons of the peronæi muſcles.

The ſuperior extremity is joined to the tibia by arthrodia; and at the lower end the cartilage ſeems to glue the two bones together; not however ſo firmly in young people, but that the motion at the other extremity of the fibula is obſervable. In old ſubjects the two bones of the leg grow together at their lower extremities.

This bone ſerves chiefly for the origin and inſertion of muſcles, and for the more firm articulation of the foot.

The rotula is the ſmall flat bone ſituated at the anterior part of the joint of the knee. It reſembles the ſection of a heart, with its point downwards. Its anterior convex ſurface is pretty ſmooth, only it has ſeveral holes into which fibres of the ſtrong ligament enter; its poſterior ſurface is ſmooth, covered with a cartilage, and divided into two cavities by a convex ridge, both adapted to the pulley of the os femoris. This ſurface is ſurrounded by a rough edge, to which the circular ligament adheres. Below theſe, the point of the bone is ſcabrous, where the ligament from the tubercle of the tibia is fixed. The ſuperior part of this bone is flat and unequal, where the tendons of the extenſors of the leg are inſerted.

The ſubſtance of the rotula is cellular, with very thin external firm plates, and ſcarce any bone of its bulk is ſo ſtrong. Beſides this, it is covered over with a thick ligament to connect its ſubſtance, and is moveable to one ſide or other; ſo that it can reſiſt the actions of the muſcles inſerted in it, or any common external force; yet a tranſverſe fracture in this bone has been obſerved to have happened from the violent effort of the muſcles.

The articulation of the rotula with the os femoris is a plain ginglymus, and with the tibia by a ſtrong ſyndeſmoſis. At the ordinary time of birth, the rotula is cartilaginous, and ſcarce grows bony ſo ſoon as moſt epiphyſes.

The two principal motions of the knee-joint are flexion and extenſion. In the former caſe, the leg may form a very acute angle with the thigh, by the condyles of the thigh-bone being round and ſmooth backwards; ſo that the rotula is pulled down by the tibia. In extending the leg, the rotula is drawn upwards and the tibia forwards by the extenſor muſcles, which, by means of the protuberant joint, and this thick bone, with its ligament, have the cord with which they act fixed to the tibia at a conſiderable angle, but are reſtrained from pulling the leg farther than to a ſtraight line with the thigh, by the poſterior croſs ligament, that the body might be ſupported by a firm column; the thigh and leg being then as little moveable as one continued bone. But when the joint is bent, the rotula is not tightly braced, and the poſterior ligament is relaxed: therefore this bone may be moved a little to either ſide, or with a ſmall rotation, by the motion of the external cavity backwards and forwards on the internal, which ſerves as an axis.

Seeing then one part of the croſs ligament is ſituated perpendicularly, and the poſterior part obliquely from the internal condyle of the thigh outwards, that poſterior part of the ligament will prevent the legs turning inwards, but not from turning outwards almoſt round, nor that motion confined by the lateral ligaments of the joint. For the arteries, veins, and nerves of the inferior extremities, ſee the articles ARTERY, NERVE, VEIN and MUSCLE.

The muſcles that move the bones of the leg on the os femoris are very long, and ſituated near each other quite round that bone. They are ten in number: 1. Rectus anterior ſive gracilis anterior. 2. Vaſtus externus. 3. Vaſtus internus. 4. Crureus. 5. Sartorius. 6. Gracilis internus ſive rectus internus. 7. Biceps. 8. Semi nervoſus. 9. Semi-membranoſus: and, 10. Poplitæus. Of all theſe the poplitæus is ſmall and ſituated below the thigh; a portion of the biceps is alſo ſmall. Theſe muſcles move the leg upon the thigh, and the thigh upon the leg, the poplitæus excepted: and the gaſtrocnemii may likewiſe perform the ſame motions, though commonly confined to the extenſion of the foot. *Winſlow.*

LEGACY ſignifies any thing that is particularly given or bequeathed by a laſt will and teſtament. See WILL and TESTAMENT.

LEGATE, a cardinal or biſhop, whom the pope ſends as his ambaſſador to ſovereign princes. See AMBASSADOR.

There are three kinds of legates, viz. legates a latere, legates de latere, and legates by office, or legati nati: of theſe the moſt conſiderable are the legate a latere, the next are the legates de latere. See the article A LATERE.

Legates by office are thoſe who have not any particular legation given them, but who by virtue of their dignity and rank in the church become legates; ſuch are the archbiſhop of Rheims and Arles; but the authority of theſe legates is much inferior to that of the legates a latere.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGEND, an idle or ridiculous ſtory told by the Romaniſts concerning their ſaints, and other perſons, in order to ſupport the credit of their religion.

LEGER-LINE, in muſic, one added to the ſtaff of five lines, when the aſcending or deſcending notes run very high or low: there are ſometimes many of theſe lines both above and below the ſtaff, to the number of four or five.

LEGGIARDO, or LEGGIARDAMENTE, in muſic, ſignifies to play or ſing in a lively, briſk, and gay manner.

LEGION, in Roman antiquity, a body of foot which conſiſted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thouſand; though Plutarch aſſures us, that after the reception of the Sabines into Rome, he encreaſed it to ſix thouſand. The common number afterwards, in the firſt times of the free ſtate, was four thouſand; but in the war with Hannibal it aroſe to five thouſand, and after this it is probable that it ſunk again to four thouſand, or four thouſand two hundred, which was the number in the time of Polybius.

LEGISLATOR, or LAW-GIVER, he who frames laws for any ſtate or kingdom.

LEGITIMATION, an act whereby illegitimate children are rendered legitimate. See the article BASTARD.

LEGUME, *Legumen*, among botaniſts, denotes a pericarpium of an oblong compreſſed figure, formed of two valves, joined by a viſible ſuture both on the upper and under parts, and having the ſeeds affixed to the upper limbs of the two valves, in an alternate order.

LEGUMINOUS, an appellation given to all plants whoſe fruit is a legume.

LEMMA, in mathematics, a previous propoſition laid down, in order to clear the way for ſome following demonſtration; and is prefixed either to the theorems or problems.

Thus to prove a pyramid one third of a priſm of the ſame baſe and height with it, as the demonſtration is difficult, this lemma may be premiſed, which is proved in progreſſion, "That the ſum of the ſeries of the ſquares of numbers in arithmetical progreſſion, beginning from 0, 1, &c. is always ſubtriple of the ſum of as many terms equal to the greateſt; or is always one third of the greateſt term multiplied by the number of terms." And in like manner, to find the inflexion of any curve, this lemma is firſt premiſed, "That a tangent may be drawn to the given curve in a given point;" and ſo in phyſics, medicine, &c.

LEMNA, duck weed, in botany, a genus of plants, producing diſtinct hermaphrodite and female flowers: neither of which have any flower petals: the ſtamina are two ſubulated filaments; and the fruit is a globoſe, unilocular capſule.

LEMON, *Limon*, in botany, a genus of trees with large ſtiff leaves like the citron, without any appendage at the bottom; the flower conſiſts of many leaves, which expand in form of a roſe: the fruit is almoſt of an oval figure, and divided into ſeveral cells, in which are lodged hard ſeeds ſurrounded by a thick fleſhy ſubſtance, which, for the moſt part, is full of an acid juice.

All ſorts are propagated by budding or inarching them either on ſtocks of lemons or citrons produced from ſeeds; but they will not readily unite on orange ſtocks; for which reaſon the citrons are preferable to either oranges or lemons for ſtocks, as they readily join with either ſort; and being of larger growth, cauſe the buds of the other ſorts to be much ſtronger than if they were on ſtocks of their own kind.

The culture of the lemon is the ſame with that of the orange-tree, with this difference only, the former being hardier than the latter, will conſequently bring their fruit to maturity with us much better than the orange will, and therefore require to have a greater ſhare of freſh air in winter; for which reaſon they ſhould always be placed nearer to the doors or windows of the green houſe: and in ſome curious gardens theſe trees have been planted againſt walls, where, by covering them with glaſſes in winter, and protecting them from ſevere froſt, they have produced plenty of large fruit: as theſe trees do generally produce ſtronger ſhoots, ſo they require more water to be given them than the orange; but as to the tender ſorts, they muſt be treated with a little more care, otherwiſe their fruit will fall off in winter, and come to nothing. See ORANGE.

LEMONADE, a liquor prepared of water, ſugar, and lemon or citron-juice: it is very cooling and grateful.

LAMURIA, a feſtival of the ancient Romans, ſolemnized on the ninth of May, to pacify the manes of the dead, who were the lemures or phantoms that came in the night to torment the living.

LENITIVE MEDICINES, among phyſicians, thoſe of a mild, ſoftening, and relaxing nature, and deſtitute of all acrimony.

LENS, in dioptrics, a ſmall oblong glaſs like a lentil; it is a medium terminated on one ſide by a ſpherical ſurface, on the other by a ſurface either plain or ſpherical. And of theſe there are five ſorts. The firſt, as A (plate LXXVIII. *fig.* 7.) is plain on one ſide, and convex on the other; the ſecond B convex on both ſides; the third plain on one ſide and concave on the other, as C; the fourth D concave on both ſides; the fifth convex on one ſide and concave on the other, as E, which is by ſome called a meniſcus.

The axis of a lens is a line paſſing perpendicularly through both its ſurfaces: thus the line F G is an axis common to all the five.

Lenſes are diſtinguiſhed into two general kinds, convex and concave: the firſt and ſecond lenſes are conſidered as convex; the third and fourth as concave: the laſt, if its convexity is greater than its concavity, is looked upon as convex; if on the contrary, it is conſidered as concave.

A lens is always ſuppoſed to conſiſt of a medium denſer than the circumambient one, unleſs where the contrary is expreſſed.

When parallel rays fall upon the ſurface of a convex lens, they are refracted towards each other in paſſing through it, and thereby collected to a focus on the other ſide.

To explain this let us trace the progreſs of a ray as A B (*fig.* 8.) through the convex lens C D E H, whoſe axis is I K. Let L be the center of the firſt convexity C D E, and M that of the other C H E: and let this ray A B be parallel to the axis; through B draw the line L N, which will be perpendicular to the ſurface C D E at that point. The ray A B in entering the denſer ſubſtance of the lens will

will be refracted towards the perpendicular, and, therefore, proceed, after it has entered the ſurface at B, in ſome direction inclined towards the axis, as BP. Through M, the center of convexity of this ſurface, and the point P, draw the line MR, which paſſing through the center will be perpendicular to the ſurface at P, and the ray now entering a rarer medium will be refracted from the perpendicular into ſome direction as PF. In like manner and for the ſame reaſons, the parallel ray ST on the other ſide the axis, and alſo all the intermediate ones as XZ, &c. will meet in the ſame point, unleſs the rays AB and ST enter the ſurface of the lens at too great a diſtance from the axis IF, the reaſon of which has already been fully explained. See REFRACTION.

The point F where the parallel rays AB, SF, &c. are ſuppoſed to be collected by paſſing through the lens CE, is called the focus of parallel rays of that lens.

If the rays converge before they enter the lens, they are then collected at a point nearer to the lens than the focus of parallel rays. If they diverge before they enter the lens, they are then collected in a point beyond F; unleſs they proceed from a point on the other ſide at the ſame diſtance with the focus of parallel rays, in which caſe they are rendered parallel. If they proceed from a point nearer than that, they diverge afterwards, but in a leſs degree than before they enter the lens.

If the lens is plain on one ſide and convex on the other, the rays are refracted the ſame way, but in a leſs degree.

Had the rays AB, ST, proceeded from a radiant point on one ſide the lens, and been collected in a focus on the other; then if they ſhould be ſuppoſed to proceed from that focal point as from a radiant, and paſs through the lens the contrary way, they would be collected in that point which was the radiant in the other caſe: and the nearer the radiant point is to the lens, the farther is the focus from it on the other ſide, and vice verſa.

If the rays AB, CD, EF, &c. (*fig.* 9.) be parallel to each other, but oblique to GH, the axis of the lens IK, or if the diverging rays CB, CF, proceed as from ſome point C which is not ſituated in the axis of the lens, they will be collected into ſome point as L, not directly oppoſite to the radiant C, but nearly ſo: for the ray CD which paſſes through M, the middle of the lens, and falls upon the ſurface of it with ſome obliquity, will itſelf ſuffer a refraction at D and N; but then it will be refracted the contrary way in one place to what it is in the other, and theſe refractions will be equal in degree, if the lens has an equal convexity on each ſide, as we may eaſily perceive, if we imagine ND to be a ray paſſing out of the lens both at N and D; for it is evident that the line ND has an equal inclination to each ſurface at both its extremities. Upon which account the difference between the ſituation of the point L and one directly oppoſite to C is ſo ſmall, that it is generally neglected; and the focus is ſuppoſed to be in that line, which a ray, that would paſs through the middle point of the lens, were it to ſuffer no refraction, would proceed in.

All which is ſufficiently clear, from what is ſaid under the article REFRACTION.

When parallel rays fall upon a concave lens, they are refracted from each other in paſſing through it, and thereby made to diverge, proceeding as from an imaginary focus on the firſt ſide of the lens.

In order to comprehend this, let ABCD (pl. LXXIX. *fig.* 1) repreſent a concave lens, EF its axis, GH the radius of the firſt concavity, IK that of the ſecond; produce GH to L, and let MG be a ray of light entering the lens at the point G. This ray, being refracted towards the perpendicular GL, will paſs on to ſome point as K in the other ſurface more diſtant from the axis than G, and being there refracted from the perpendicular IK, will be diverted farther ſtill from the axis, and proceed in the direction KN as from ſome point as O on the firſt ſide of the lens. In like manner other rays as PQ, parallel to the former, will proceed after refraction at both ſurfaces as from the ſame point O; which upon that account will be the imaginary focus of parallel rays of this lens.

If the rays diverge before they enter the lens, their imaginary focus is then nearer the lens than that of the parallel rays. If they converge before they enter the lens, proceeding towards ſome diſtant point in the axis as E, they are then rendered leſs converging; if they converge to a point at the ſame diſtance from the lens with the focus of parallel rays, they then go out parallel; if to a point at leſs diſtance, they remain converging, but in a leſs degree than before they entered the lens.

When the rays enter the lens diverging, the nearer their radiant point is to it, the nearer alſo is their imaginary focus after refraction, and vice verſa.

If the lens is plain on one ſide and concave on the other, the rays ſuffer a like refraction in each caſe, but in a leſs degree.

The truth of what has been ſaid concerning the paſſage of rays through a concave lens, is eaſily to be deduced from the laws of refraction.

But the method of determining the exact focal diſtance of lenſes is to be had from the propoſitions laid down and demonſtrated in the article REFRACTION. Thus the progreſs of the rays, after their refraction at the firſt ſurface where they enter a lens, is had by one of thoſe which determines the focal diſtance of rays entering a denſer medium of ſuch form: and their progreſs, after their refraction at the other ſurface where they go out, is had by computing what progreſs rays, moving in the direction they are found to have after their entrance at the firſt ſurface, will acquire by being refracted at the other; which is to be effected by one who determines the focal diſtance of rays paſſing out of a denſer medium of like form with that of the lens.

When a ray paſſes through a medium terminated by two plain and parallel ſurfaces, it is refracted one way in going out of the ſecond, as much as it was the other in entering the firſt; and, therefore, proceeds afterwards, not in the ſame direction, but in one which is parallel to that which it had before.

Thus, if the ray AB (*fig.* 2.) enters the denſer medium CDEF terminated by the parallel ſurfaces CD and EF, it is refracted at B towards the perpendicular BI, proceeding to a point at G, where it is as much refracted from the perpendicular GK in going out, and proceeds in the direction GH, not the ſame, but parallel to the former ABL.

LENT, a ſolemn time of faſting in the Chriſtian church, obſerved as a time of humiliation before Eaſter, the great feſtival of our Saviour's reſurrection.

Thoſe of the Romiſh church, and ſome of the proteſtant communion, maintain, that it was always a faſt of forty days, and as ſuch, of apoſtolical inſtitution. Others think it was only of eccleſiaſtical inſtitution, and that it was variouſly obſerved in different churches, and grew by degrees from a faſt of forty hours, to a faſt of forty days. This is the ſentiment of Morton, biſhop Taylor, du Moulin, Daillé, and others.

The Chriſtians of the Greek church obſerve four Lents; the firſt commences on the fifteenth of November, or forty days before Chriſtmas; the ſecond is the ſame with our Lent; the third begins the week after Whitſuntide, and continues till the feſtival of St. Peter and St. Paul; and the fourth commences on the firſt of Auguſt, and laſts no longer than till the fifteenth. Theſe Lents are obſerved with great ſtrictneſs and auſterity; but on Saturdays and Sundays they indulge themſelves in drinking wine and uſing oil, which are prohibited on other days.

LENTA FEBRIS, the ſlow fever. See the article FEVER.

LENTIGO, FRECKLES, in medicine. See the article FRECKLES.

LENTISCUS, the lentiſk or maſtich-tree, in botany, a genus of trees, very nearly allied to the terebinthus, or turpentine-tree, in its characters, but differing in that the leaves are pennated; but there is no ſingle leaf to terminate the end of each compound one. See the article MASTICH.

LEO, the lion, in zoology. See LION.

LEO, in aſtronomy, one of the twelve ſigns of the zodiac, the fifth in order, containing, according to Ptolemy, thirty-two ſtars; according to Tycho, thirty-ſeven and

and, in the Britannic catalogue, there are no leſs than ninety-four.

The ſtar called the lion's heart, cor leonis, regulus, and baſilicus, is a fixed ſtar of the firſt magnitude.

LEONINE VERSES, ſuch as rhyme at every hemiſtich, the middle ſyllable of each verſe correſponding to the laſt one.

LEONTODON, dandelion, in botany, a genus of plants, the compound flower of which is imbricated and uniform; and the partial ones, monopetalous and ligulated; the ſtamina are five ſcarcely diſcernible capillary filaments: the ſeed, which is ſolitary, is contained in the cup of each partial flower, or corollula.

Dandelion is ſaid to have much the ſame virtues with endive. See ENDIVE.

LEONURUS, lion's tail, a genus of plants, the flower of which is monopetalous and ringent; and its ſeeds, which are four in number, are contained in the bottom of the cup.

LEOPARD, a beaſt of prey, with the ſpots on the upper part of the body round, and the lower ones virgated. It is a very nimble, as well as fierce animal, ſo that ſcarce any thing eſcapes it.

Authors called the male pardus, and the female panthera.

LEOPARD'S BANE, doronicum, in botany. See the article DORONICUM.

LEPIDIUM, dittander, in botany, a genus of plants, with a tetrapetalous cruciform flower: the ſtamina are ſix ſubulated filaments; and the fruit is a compreſſed bilocular pod.

LEPIDOPTERA, in zoology, an order of inſects, with four wings, which are covered with imbricated ſquamulæ: add to this, that the mouth is commonly ſpiral.

Under this order are comprehended the butterflies, and phalenæ, or moths.

LEPROSY, *Lepra*, in phyſic, a higher degree of cutaneous diſorder than an itch, the ſame with lepra arabum. See ITCH, IMPETIGO, and ELEPHANTIASIS.

The word is derived from the Greek λεπρα, ſignifying the ſame, and that from λεπις, a ſcale.

There is a wide difference between the itch and leproſy, and that ulcerous diſorder in which white ſordid ulcers, ſeizing principally the muſcular parts, ſuch as the back, arms, thighs, &c. diſcharge a putrid ſanies, and ſometimes appearing in one limb, and ſometimes in another, often continue for many years. Large quantities of worms are alſo found lodged within theſe ulcers, ſo that they can hardly be extirpated.

The lepra and elephantiaſis are diſeaſes nearly alike.

The method for the cure of theſe and ſuch like malignant diſorders is to diſcharge the maſs of corrupt, glutinous, and acrid humours, by ſufficient bleeding and abſtinence, by purges both gentle and draſtic, and then by a proper regimen. But if the growing and refractory ſtate of the diſeaſe raiſes a ſuſpicion of malignity, there are no remedies more powerful, if the patient's ſtrength permit, than mercury and its preparations. Some make an unguent of live mercury thoroughly extinguiſhed with pomatum, adding flowers of ſulphur and camphire, with which the joints, ancles, &c. are to be well rubbed. But others chooſe a better and ſafer method of uſing mercury internally; whilſt, by a previous preparation of the body, by alteratives, correctors, and evacuants, mercurius dulcis, with double the quantity of crabs-eyes, and diaphoretic antimony, is duly exhibited. This intention is alſo anſwered by mercurius ſolaris and jovialis, of which a few grains, with conſerve of roſes, may be exhibited every morning, drinking in bed, after it, a pint of ſome proper decoction. Each of theſe methods requires a very temperate air, a ſpare diet, and abſtinence from pinguious or boiled fleſh and acids.

But if the patient be either an infant, or too old, both the ancients and moſt judicious of the moderns have greatly extolled preparations of milk, eſpecially aſſes milk, the whey of cows and goats milk, and milk mixed with water.

Whenever theſe exanthematous diſorders are ſupported by a ſcorbutic lues, or hypochondriac affection, a much greater advantage will be procured, when the milk diet is ſo managed as to alleviate the other diſorder with which they are complicated: for which purpoſe the beſt way is the due uſe of medicinal waters, eſpecially thoſe of a temperate kind, impregnated with a ſaline and ſpirituous principle. But if ſuch waters cannot be had, the end will be beſt anſwered by a decoction of ſuch herbs as depurate the blood, and are particularly deſtined to theſe diſorders, with milk or whey, both ſweet and ſomewhat ſour. *Francis Hoffman.*

LEPUS, the hare, in zoology. See HARE.

LEPUS, in aſtronomy, a conſtellation of the ſouthern hemiſphere; comprehending twelve ſtars, according to Ptolemy; thirteen, according to Tycho; and nineteen in the Britannic catalogue.

LESSONS, among eccleſiaſtical writers, portions of the Holy Scripture, read in Chriſtian churches at the time of divine ſervice.

LETHARGY, *Lethargus*, in phyſic, a kind of diſorder wherein the perſon affected labours under a heavy and perpetual ſleep, with ſcarce any interval of waking.

The word is derived from the Greek λήθη, ſleep, and ἀργὸς, ſlothful.

There are ſeveral ſpecies of this diſorder; the chief are coma vigil, coma ſomnolentum, carus, and a lethargy. See COMA, CARUS, &c.

LETHE, in the ancient mythology, one of the rivers of hell, ſignifying oblivion or forgetfulneſs; its waters having, according to poetical fiction, the peculiar quality of making thoſe who drank of them entirely forget every thing that was paſt.

LETTER, *Litera*, a character either in print or writing, which men have agreed on to ſignify ſomething, by joining of which they make their thoughts known to one another.

The alphabet of every language conſiſts of a certain number of letters or characters, which have a different ſound, form, and ſignification. See ALPHABET.

The articulation of words, or formation of the ſeveral letters, begins when the breath has paſt the throat; and is almoſt performed by the noſtrils, mouth, tongue, and lips.

Some ſay that Fohi, firſt king among the Chineſe, and 2950 years before Chriſt, invented letters, having writ in their language a book called Yexim. Others think from mummies and obeliſks, that hieroglyphics were the firſt manner of writing, they being prior to Moſes, as moſt of the obeliſks and pyramids were made, while the Iſraelites were in Egypt. The Chaldeans or Phœnicians, it is very likely, were the maſters of the Egyptians; whence it was that thoſe letters were called Phœnician by the Greeks: yet, according to Diodorus Siculus, they only changed the form of letters.

Pliny will have the moſt ancient letters to have been the Aſſyrian, and that Cadmus, about two hundred and fifty years before the Trojan war, brought ſixteen of them from Phœnicia into Greece, namely, A, B, C, D, E, F, I, L, M, N, O, P, R, S, T, U, to which Palamedes, during the Trojan war, had added four, Θ Ξ Φ Υ.

Simonides, Evander, and Demaratus, were the firſt that brought letters into Italy.

The Hebrews made a diviſion of their letters into guttural, viz. *a, h, ch, gn,* or *aleph, he, cheth, hain*; dental, as *z, s, r, zain, tſadde, reſh*; labial, *b, m, n, p, beth, mem, vau, phe*; and thoſe of the tongue, *d, t, l, n*; or *daleth, tau, lamed, nun*; and palatal, as *g, i, c, k, ghimel, jod, caph, coph.*

The letters F, G, H, K, Q, X, Y, Z, were formerly unknown to the Romans. One letter was intended to ſignify only one ſound, and not as at preſent now to expreſs one ſound, and then another, which has introduced that confuſion which has rendered the learning of our modern tongue extremely difficult.

Grammarians diſtinguiſh their letters into vowels and conſonants; into mutes, diphthongs, liquids, and characteriſtics. Printers diſtinguiſh their letters into capital, majuſcule, initial, or upper-caſe letters, which ſerve for the titles of books, &c. and minuſcule, ſmall or under-caſe letters, which are again divided into pearl, nonpareil, pica, and great canon.

Letters, again, are of various ſizes, each of which are ſometimes caſt with the Roman, ſometimes Italic, ſometimes

times an Engliſh, or black letter face. There are alſo bodies with the Greek, Hebrew, Arabic, the muſic face, &c.

A ſet or fount of any of theſe ſizes includes current letters, capitals, numeral figures, points, ſpaces, &c. See FOUNT.

Letters are the elements of grammar; an aſſemblage of theſe compoſes ſyllables, of thoſe words, and of theſe ſentences.

Numeral LETTERS, thoſe uſed inſtead of cyphers, in order to expreſs numbers, as C, D, I, L, M, V, X.

LETTER alſo denotes the ſame with epiſtle, a writing addreſſed to any perſon.

LETTER *of Attorney*, a writing authoriſing any perſon to do ſome lawful act for another, as to give ſeizin of lands, receive debts, ſue a third perſon, &c.

LETTER *of Credit*, among merchants, is a letter wrote by a merchant or banker to his correſpondent abroad, requeſting him to credit the bearer as far as a certain ſum. See CREDIT.

LETTER *of Licence*, an inſtrument or writing granted by a perſon's creditors, allowing him a certain time for the payment of his debts; by which means he is enabled to proſecute his buſineſs, without fearing an arreſt.

LETTER *of Mart*, or *Marque*, a letter granted to one of the king's ſubjects, under the privy ſeal, impowering him to make repriſals for what was formerly taken from him by the ſubjects of another ſtate, contrary to the law of mart. See MARQUE.

Monitory LETTERS. See MONITORY.

LETTERS-PATENT, or OVERT, are writings ſealed with the great ſeal of England, ſo called, becauſe they are open with the ſeal affixed to them. Theſe are granted to authoriſe a man to do, or enjoy, what of himſelf he could not do. See the article PATENT.

Paciſic LETTERS, *Literæ Pacificæ*, in church-hiſtory, teſtimonial letters given by the biſhop, or chorepiſcopus, to their prieſts, when they had occaſion to travel abroad, certifying that the bearer was a catholic, and in communion with the church.

Paſchal LETTER, a letter written by the pope to all metropolitans, to inform them on what day Eaſter was to be celebrated.

LEVARI FACIAS, is a writ directed to the ſheriff for levying a certain ſum of money upon the lands, &c. of a perſon who has forfeited his recognizance.

LEVATOR, in anatomy, a name applied to ſeveral muſcles in the body, that ſerve to raiſe the parts to which they belong. See ELEVATOR.

LEVATOR *ſcapulæ proprius*, in anatomy, or rather, according to Winſlow, *angularis*, is a long and pretty thick muſcle, about two fingers in breadth, lying above the ſuperior angle of the ſcapula, along the poſterior lateral part of the neck of that bone. It is inſerted above in the tranſverſe apophyſes of the four firſt vertebra of the neck, by four fleſhy branches ending in ſhort tendons. From thence theſe branches run down a little obliquely, and then uniting are inſerted into the ſuperior angle of the ſcapula and in the edge of its baſis, and from thence to the ſmall triangular ſpace, being there covered a little by the rhomboides: it is alſo covered by the trapezius. By its inſertion in the ſuperior angle of the ſcapula, it moderates the deſcent of that angle, while the trapezius and ſerratus major raiſe the acromium. Afterwards, when theſe two muſcles ceaſe to act, the angularis raiſes the ſuperior angle, and by that means depreſſes the acromium.

LEVATORES *Ani*, in anatomy, are muſcles that ariſe fleſhy from each ſide of the oſſa pubis, internally within the pelvis, as alſo from part of the os iſchium and ſacrum; from thoſe places, like lines drawn from a circumference towards a center, its fibres deſcend, over the muſculi marſupiales, to their implantation at the lower end of the inteſtinum rectum in the anus. They chiefly ſerve to ſuſpend and draw the anus upwards, leſt the fæces ſhould be burdenſome to the ſphincter. In their deſcent, on each ſide forwards, from the oſſa pubis, they paſs cloſe over the glandulæ proſtatæ, in a manner embracing them, whereby they are rendered capable of compreſſing them; and by a retraction of the anus, at the ſame time act on the veſiculæ ſeminales, in order to promote the emiſſion of the ſemen in coitu. *Cowper.*

LEUCADENDRON, in botany, a genus of plants, the general corolla of which is uniform and convex; the partial one of which is oblong, hoary on the outſide, and compoſed of two petals; the upper petal is a long line or unguis, and its limb is lanceolated, undivided, and in its lower part is firmly joined to the lower petal; the lower petal has alſo a long unguis of a linear figure, but three times as broad as that of the upper petal; the cup, ſcarce at all altered, ſerves inſtead of a pericarpium, and contains a ſingle roundiſh ſeed, coronated with hairs.

LETTUCE, *Lactuca*, in botany, a genus of plants, with a fibroſe root, which is, for the moſt part, annual: the leaves are ſmooth, and grow alternately upon the branches; the ſtalks are, for the moſt part, ſlender and ſtiff, and commonly terminate into a ſort of umbel; the cup of the flower is oblong, ſlender, and ſcaly; the ſeeds are oblong, depreſſed, and generally terminate in a point.

It would be beſide my purpoſe to mention in this place the ſeveral ſorts of lettuce that are to be found in botanic writers, many of which are plants of no uſe, and are never cultivated but in botanic gardens for variety; and ſome of them are found wild in many parts of England. I ſhall therefore paſs over thoſe here, and only mention the ſeveral ſorts which are cultivated in the kitchen garden for uſe: 1. Common or garden lettuce. 2. Cabbage lettuce. 3. Cilicia lettuce. 4. Dutch brown lettuce. 5. Aleppo lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Verſailles or upright white cos lettuce. 9. Black cos. 10. White cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

The firſt of theſe ſorts is commonly ſown very early for cutting, to mix with other ſmall ſallad-herbs, and is only different from the ſecond ſort, in being a degeneracy therefrom; or otherwiſe the ſecond is an improvement by frequent cultivation from the firſt: for if the ſeeds are ſaved from ſuch plants of the ſecond ſort as did not cabbage cloſely, the plants produced from that ſeed will all degenerate to the firſt ſort; which is by the gardeners called lapped lettuce, to diſtinguiſh it from the other, which they call cabbage lettuce. The ſeeds of the firſt, which are commonly ſaved from any of the plants, without having any regard to their goodneſs, are generally ſold at a very cheap rate, eſpecially in dry ſeaſons, when theſe plants always produce the greateſt quantity of ſeeds; though ſometimes this ſeed is ſold in the ſeed ſhops, and by perſons who make a trade of ſelling ſeeds, for the cabbage lettuce; which is often the occaſion of people's being diſappointed in their crop: ſo that this ſort ſhould never be cultivated, but to be cut up very young; for which purpoſe this is the only good ſort, and may be ſown any time of the year; obſerving only in hot weather to ſow it on ſhady borders, and in the ſpring and autumn upon warm borders; but in winter it ſhould be ſown under glaſſes, otherwiſe it is ſubject to be deſtroyed by ſevere froſts.

The cabbage lettuce may alſo be ſown at different times of the year, in order to have a continuation of it through the whole ſeaſon. The firſt crop is generally ſown in February; which ſhould be upon an open warm ſpot of ground, and when the plants are come up, they ſhould be thinned out to the diſtance of ten inches each way; which may be done by hoeing them out, as is practiſed for turneps, carrots, onions, &c. provided you have no occaſion for the ſuperfluous plants; otherwiſe they may be drawn up, and tranſplanted into another ſpot of good ground at the ſame diſtance; which if done before the plants are too large, they will ſucceed very well, though they will not be ſo large as thoſe which were left upon the ſpot where they were ſown; but they will come ſomewhat later, which will be of ſervice, where people do not ſow every month.

The Cilicia, imperial, royal, black, white, and upright cos lettuces may be ſown at the following times: the firſt ſeaſon for ſowing theſe ſeeds is at the end of February, or the beginning of March, upon a warm light ſoil, and an open ſituation; i. e. not overſhadowed with trees: and, when the plants are come up, they ſhould be either hoed out, or tranſplanted into another ſpot of ground, as was directed for the cabbage lettuce, obſerving

ing to leave theſe ſorts fifteen or ſixteen inches apart each way; which will be full near enough for theſe plants, eſpecially if the ſoil be good; and you muſt carefully keep them clear from weeds, which is the only culture they will require, except the black cos lettuce, which ſhould be tied up when they are full grown, to whiten their inner leaves, and render then criſp; otherwiſe they are ſeldom good for much, rarely cabbaging without this aſſiſtance.

You may alſo continue theſe ſorts through the ſeaſon, by ſowing them in April, May, and June; obſerving to ſow the late crops in a moiſt ſhady ſituation, otherwiſe they will run up to ſeed before they grow to any ſize; but in Auguſt, toward the latter end, you may ſow of theſe ſorts, to abide the winter; which plants ſhould be tranſplanted either under glaſſes, or into a hot-bed, which ſhould be arched over with hoops, in order to be covered in winter, otherwiſe in hard winters they are often deſtroyed; but you muſt conſtantly let theſe plants have as much open free air as poſſible, when the weather is mild; only covering them in hard rains, or froſty weather; for if they are kept cloſely covered in winter, they will be ſubject to a mouldineſs which ſoon rots them.

The moſt valuable of all the ſorts of lettuce in England are the Egyptian green cos, and the Verſailles or white cos, the Cilicia, and black cos; though ſome people are very fond of the royal and imperial lettuces; but they ſeldom ſell ſo well in the London markets as the others, nor are ſo generally eſteemed. Indeed of late years, ſince the white cos has been commonly cultivated, it has obtained the preference of all the other ſorts, until the Egyptian green cos was introduced; which is ſo much ſweeter and tenderer than the white cos, that it is by all good judges eſteemed the beſt ſort of lettuce known. This ſort will endure the cold of our ordinary winters full as well as the white cos; but at the ſeaſon of its cabbaging, if there happens to be much wet, this ſort, being very tender, is very ſubject to rot.

The brown Dutch and green capuchin lettuces are very hardy, and may be ſown at the ſeaſons as was directed for the common cabbage lettuce; and are very proper to plant under a wall or hedge to ſtand the winter; where many times theſe will abide, when moſt of the other ſorts are deſtroyed; and therefore they will prove very acceptable at a time when few other ſorts are to be had; they will alſo endure more heat and drought than moſt other ſorts of lettuce, which renders them very proper for late ſowing; for it often happens, in very hot weather, that the other ſorts of lettuce will run up to ſeed in a few days after they are cabbaged; whereas theſe will abide near three weeks in good order, eſpecially if care be taken to cut the forwardeſt firſt, leaving thoſe that are not ſo hard cabbaged to be laſt. In ſaving of theſe ſeeds, the ſame care ſhould be taken to preſerve only ſuch as are very large, and well cabbaged, otherwiſe the ſeeds will degenerate, and be good for little.

The red capuchin, Roman, and prince lettuces are pretty varieties, and cabbage very early; for which reaſon a few of them may be preſerved; as may ſome of the Aleppo, for the beauty of its ſpotted leaves; though very few people care for either of theſe ſorts at table, when the other more valuable ones are to be obtained; but in a ſcarcity, theſe may ſupply the place pretty well; and theſe ſorts are very proper for ſoups. The ſeeds of theſe muſt alſo be ſaved from ſuch as cabbage beſt, otherwiſe they will degenerate, and be good for little: *Miller's Gard. Dict.*

LEVEL, an inſtrument to draw a line parallel to the horizon, whereby the difference of aſcent or deſcent between ſeveral places may be found, for conveying water, draining fens, &c.

The word is derived from the Latin, *libella*, the croſs beam in a balance, which, to be juſt, muſt ſtand exactly horizontal.

Air LEVEL, that which ſhews the line of level by means of a bubble of air incloſed with ſome liquor in a glaſs tube, whoſe two edges are ſealed hermetically. When the bubble fixes at a mark made exactly in the middle of the tube, the plane where it is fixed is level; otherwiſe the bubble will riſe to one end.

The liquor with which the tube is filled is oil of tartar, or aqua-ſecunda; theſe not being liable to freeze.

Air LEVEL, with ſights, conſiſts of an air level (plate LXXIX. *fig.* 3.) about eight inches long, and ſeven or eight in diameter, ſet in a braſs tube, with an aperture in the middle. The tubes are carried in a ſtrong ſtraight ruler, a foot long, at whoſe ends are fixed two ſights exactly perpendicular to the tubes, and of an equal height, having a ſquare hole, formed by two fillets of braſs, croſſing each other at right angles, in the middle of which is drilled a very little hole, through which a point on a level with the inſtrument is deſcribed.

The braſs tube is faſtened on the ruler by means of two ſcrews; one of which, marked 4, ſerves to raiſe or depreſs the tube at pleaſure, to bring it to a level. The top of the ball and ſocket is rivetted to a little ruler that ſprings, one end of which is faſtened with ſcrews to the great ruler, and the other end has a ſcrew 5, ſerving to raiſe or depreſs the inſtrument when nearly level.

The following is a more commodious inſtrument.

Air LEVEL, with teleſcope ſights; this level (*fig.* 4.) only differs from the laſt, in that, inſtead of plain ſights, it carries a teleſcope.

This was invented by M. Huygens; which has this advantage, that it may be inverted by turning the rule and teleſcope half round; and then, if the hair cut the ſame point that it did before the turn, it is a proof the operation is juſt.

It may be obſerved, that one may add a teleſcope to any kind of level, by applying it upon a parallel to the baſe or ruler, when there is occaſion to take the level of remote objects.

Dr. Deſaguliers contrived an inſtrument, by which the difference of level of two places, which could not be taken in leſs than four or five days with the beſt teleſcope-levels, may be taken in as few hours. The inſtrument is as follows: to the ball C (*fig.* 7.) is joined a recurve tube B A, with a very fine bore, and a ſmall bubble at top, A, whoſe upper part is open. It is evident from the make of this inſtrument, that if it be inclined in carrying, no prejudice will be done to the liquor, which will always be right both in the ball and tube, when the inſtrument is ſet upright. If the air at C, be ſo expanded with heat, as to drive the liquor to the top of the tube, the cavity A will receive the liquor, which will come down again and ſettle at D, or near it, according to the level of the place where the inſtrument is, as ſoon as the air at C returns to the ſame temperament as to heat and cold. To preſerve the ſame degree of heat, when the different obſervations are made, the machine is fixed in a tin veſſel F E, filled with water up to *g h*, above the ball, and a very ſenſible thermometer has alſo its ball under water, that one may obſerve the liquor at D, in each experiment, when the thermometer ſtands at the ſame height as before. The water is poured out when the inſtrument is carried, which one may do conveniently by means of the wooden frame, which is ſet upright by three ſcrews S, S, S, (*fig.* 8.) and a line and plummet P P. The back part of the wooden frame is repreſented by *fig.* 6. where from a piece at top K hangs the plummet P, over a braſs point at N; M *m* are brackets, to make the upright board K N continue at right angles, with the horizontal one at N; *fig.* 5. repreſents a front view of the machine, ſuppoſing the fore-part of the tin-veſſel tranſparent; and here the braſs-ſocket of the recurve-tube, into which the ball is ſcrewed, has two wings at I I, fixed to the bottom, that the ball may not break the tube by its endeavour to emerge, when the water is poured in as high as *g h*.

After the Dr. had contrived this machine, he conſidered, that as the tube is of a very ſmall bore, if the liquor ſhould riſe into the ball at A, in carrying the inſtrument from one place to another, ſome of it would adhere to the ſides of the ball A, and upon its deſcent in making the experiment, ſo much might be left behind, that the liquor would not be high enough at D (*fig.* 7.) to ſhew the difference of the level; therefore, to prevent that inconveniency, he contrived a blank ſcrew, to ſhut up the hole at A, as ſoon as one experiment is made, that in carrying the machine, the air in A may ballance that in C, ſo that the liquor ſhall not run up and down the tube, whatever degree of heat and cold may act upon the inſtrument, in going from one place to another. Now becauſe one experiment may be made in the morning, the water may be

ſo cold, that when a ſecond experiment is made at noon, the water cannot be brought to the ſame degree of cold it had in the morning; therefore, in making the firſt experiment, warm water muſt be mixed with the cold, and when the water has ſtood ſome time before it comes to be as cold as it is likely to be at the warmeſt part of that day, obſerve and ſet down the degree of the thermometer at which the ſpirit ſtands, and likewiſe the degree of the water in the barometer at D; then ſcrew on the cap at A, pour out the water, and carry the inſtrument to the place whoſe level you would know; then pour in your water, and when the thermometer is come to the ſame degree as before, open the ſcrew at top, and obſerve the liquor in the barometer.

The doctor's ſcale for the barometer is ten inches long, and divided into tenths; ſo that ſuch an inſtrument will ſerve for any heights not exceeding ten feet, each tenth of an inch anſwering to a foot in height.

The Dr. made no allowance for the decreaſe of denſity in the air, becauſe he did not propoſe this machine for meaſuring mountains, (though with a proper allowance for the decreaſing denſity of the air, it will do very well) but for heights that want to be known in gardens, plantations, and the conveyance of water; where an experiment that anſwers two or three feet in a diſtance of twenty miles, will render this a very uſeful inſtrument.

Foot LEVEL. See the article FOOT *Level.*

Artillery-Foot LEVEL, in gunnery, is in form of a ſquare, having its two legs or branches of an equal length, at a juncture whereof is a little hole, whence hangs a thread and plummet, playing on a perpendicular line in the middle of a quadrant. It is divided into twice 45 degrees from the middle. Plate LXXIX. *fig.* 9.

This inſtrument may be uſed on other occaſions, by placing the ends of its two branches on a plane; for when the thread plays perpendicularly over the middle diviſion of the quadrant, that plane is aſſuredly level. To uſe it in gunnery, place the two ends on the piece of artillery, which you may raiſe to any propoſed height, by means of the plummet, whoſe thread will give the degree above the level.

Carpenter's and Paviour's LEVEL, conſiſts of a long ruler, in the middle whereof is fitted, at right angles, another ſomewhat bigger, at the top of which is faſtened a line, which, when it hangs over a fiducial line at right angles with the baſe, ſhews that the ſaid baſe is horizontal. Sometimes this level is all of one board.

Gunner's LEVEL, for levelling cannons and mortars, conſiſts of a triangular braſs-plate, about four inches high, (*fig.* 10.) at the bottom of which is a portion of a circle, divided into 45 degrees, which number is ſufficient for the higheſt elevation of cannons and mortars, and for giving ſhot the greateſt range: on the center of this ſegment of a circle is ſcrewed a piece of braſs, by means of which it may be fixed or ſcrewed at pleaſure; the end of this piece of braſs is made ſo as to ſerve for a plummet and index, in order to ſhew the different degrees of elevation of pieces of artillery. This inſtrument has alſo a braſs-foot, to ſet upon cannons or mortars, ſo as when thoſe pieces are horizontal, the inſtrument will be perpendicular. The foot of this inſtrument is to be placed on the piece to be elevated, in ſuch a manner, as that the point of the plummet may fall on the proper degree: this is what they call levelling the piece.

Maſon's LEVEL, is compoſed of three rules, ſo joined as to form an iſoſceles-rectangle, ſomewhat like a Roman A, at the vertex whereof is faſtened a thread, from which hangs a plummet, that paſſes over a fiducial line, marked in the middle of the baſe, when the thing, to which the level is applied, is horizontal; but declines from the mark, when the thing is lower on one ſide than on the other.

Plumb or *Pendulum* LEVEL, that which ſhews the horizontal lines by means of another line perpendicular to that deſcribed by a plummet or pendulum. This inſtrument, (*fig.* 12.) conſiſts of two legs or branches, joined together at right angles, whereof that which carries the thread and plummet is about a foot and a half long; the thread is hung towards the top of the branch, at the point 2. the middle of the branch where the thread paſſes is hollow, ſo that it may hang free every where; but towards the bottom, where there is a little blade of ſilver, whereon is drawn a line perpendicular to the teleſcope, the ſaid cavity is covered by two pieces of braſs, making as it were a kind of caſe, leſt the wind ſhould agitate the thread, for which reaſon the ſilver-blade is covered with a glaſs G, to the end that it may be ſeen when the thread and plummet play upon the perpendicular: the teleſcope is faſtened to the other branch of the inſtrument, and is about two feet long; having an hair placed horizontally acroſs the focus of the object-glaſs, which determines the point of the level. The teleſcope muſt be fitted at right angles to the perpendicular. It has a ball and ſocket by which it is faſtened to the foot, and was invented by Mr. Picard.

Reflecting LEVEL, that made by means of a pretty long ſurface of water, repreſenting the ſame object inverted which we ſee erected by the eye, ſo that the point where theſe two objects appear to meet, is a level with the place where the ſurface of the water is found. This is the invention of M. Mariotte.

There is another reflecting level, conſiſting of a mirror of ſteel, or the like, well poliſhed, and placed a little before the object-glaſs of a teleſcope, ſuſpended perpendicularly. This mirror muſt make an angle of 45° with the teleſcope, in which caſe the perpendicular line of the ſaid teleſcope is converted into a horizontal line, which is the ſame with the line of level. This is the invention of M. Caſſini.

Water-LEVEL, that which ſhews the horizontal line by means of a ſurface of water or other liquor, founded on this principle, that water always places itſelf level. See the article FLUID.

The moſt ſimple is made of a long wooden trough, or canal, whoſe ſides are parallel to the baſe, ſo that being equally filled with water, its ſurface ſhews the line of level. This is the chorobates of the ancients. See CHOROBATES.

It is alſo made with two cups fitted to the two ends of a pipe, three or four feet long, about an inch in diameter, by means whereof the water communicates from the one to the other cup; and this pipe being moveable on its ſtand by means of a ball and ſocket, when the two cups become equally full of water, their two ſurfaces mark the line of level.

This inſtrument, inſtead of cups, may alſo be made with two ſhort cylinders of glaſs three or four inches long, faſtened to each extreme of the pipe with wax or maſtic. Into the pipe is poured ſome common or coloured water, which ſhews itſelf through the cylinders, by means whereof the line of level is determined; the height of the water, with reſpect to the center of the earth, being always the ſame in both cylinders: this level, though very ſimple, is yet very commodious for levelling ſmall diſtances.

LEVEL *of Mr. Huygens's Invention*, conſiſts of a teleſcope *a*, (*fig.* 11.) in form of a cylinder going through a ferril, in which it is faſtened by the middle. This ferril has two flat branches *b b*, one above, and the other below, at the ends whereof are faſtened little moving pieces which carry two rings, by one of which the teleſcope is ſuſpended to an hook at the end of the ſcrew 3, and at *b* the other a pretty heavy weight is ſuſpended, in order to keep the teleſcope in equilibrio. This weight hangs in the box 5, which is almoſt filled with linſeed-oil, oil of walnuts, or other matter that will not eaſily coagulate, for more aptly ſettling the ballance of the weight and teleſcope. The inſtrument carries two teleſcopes cloſe and very parallel to each other; the eye-glaſs of the one being againſt the object-glaſs of the other, that one may ſee each way without turning the level. In the focus of the object-glaſs of each teleſcope muſt a little hair be ſtrained horizontally, to be raiſed and lowered by a little ſcrew. If the tube of the teleſcope be not level, when ſuſpended, a ferril, or ring 4, is put on, to be ſlid along till it be level. The hook on which the inſtrument is hung, is fixed to a flat wooden croſs; at the end of each arm is a hook to keep the teleſcope ſteady: to the flat croſs is applied another hollow one that ſerves as a caſe for the inſtrument; but the two ends are open, that the teleſcope may be ſecured from the weather, and always ready for uſe. The foot of the inſtrument is a round braſs plate, to which are faſtened

faſtened three braſs ferrils, moveable by means of joints, wherein are ſtaves; and on this foot is placed the box.

LEVELLING, the finding a line parallel to the horizon, at one or more ſtations, and ſo to determine the height of one place with regard to another. See LEVEL.

A truly level ſurface is a ſegment of any ſpherical ſurface which is concentric to the globe of the earth. A true line of level is an arch of a great circle which is imagined to be deſcribed upon a truly level ſurface.

The apparent level is a ſtraight line drawn tangent to an arch or line of true level. Every point of the apparent level, except the point of contact, is higher than the true level: thus (plate LXXIX. *fig.* 13.) let EAG be an arch of a great circle drawn upon the earth; to a perſon who ſtands upon the earth at A, the line HD is the apparent level, parallel to his rational horizon RR; but this line, the further it is extended from his ſtation A, the further it recedes from the center; for BC is longer than AC, and DC is longer than BC, &c.

The common methods of levelling are ſufficient for laying pavements of walks, for conveying water to ſmall diſtances, for placing horizontal dials, or aſtronomical inſtruments: but, in levelling the bottoms of canals which are to convey water to the diſtance of many miles, the difference between the apparent and true level muſt be taken into the account; thus (*fig.* 14.) let IALbe an arch of a great circle upon the earth; let it be required to cut a canal, whoſe bottom ſhall be a true level from A to B, of the length of 5078 feet; the common method is to place the levelling inſtrument in the bottom of the canal at A, and, looking through the ſights placed horizontally at a ſtick ſet up perpendicular at B, to make a mark where the viſual ray or line of the apparent level points, as E, and then to ſink the bottom of the canal at B, as much below E as A is below D: but this will not give us a true level, for, according to Caſſini's calculation, at the diſtance of 5078 feet, the apparent level is ſeven inches above the true; and therefore, to make a true level B muſt be ſunk ſeven inches lower than the apparent level directs; ſo that if A be four feet below D, B muſt be four feet ſeven inches below the mark E. We have here mentioned the error which will ariſe from placing the level at one end of the line to be levelled, and ſhewn how to correct it; but in moſt caſes it is better to take a ſtation in the middle of the line to be levelled; thus, if the points H and B are to be levelled, place the inſtrument in the middle at A, and, ſetting up ſticks perpendicular at H and B, make marks upon each ſtick where the apparent level points, as E and F; thoſe points are level: and if you ſink H as much below F as B is below E, HABwill be a true level. When the bottom of a canal is thus truly level, if water be let in at one end, it will riſe to the ſame height at the other. If water be required to run with any velocity, that is of another conſideration: a river will run, though very ſlowly, which hath not above ſix inches deſcent below the true level for a mile in length: if a river whoſe water is foul be required to run with ſuch a velocity as to carry its foulneſs into the ſea, ſixteen inches, or at leaſt one foot fall below the true level, in a mile running, have been thought ſufficient, by perſons ſkilful in that affair. Vid. Riccioli Geogr. Reformat. l. 6. c. 24.

This we thought neceſſary to premiſe before we explained the method uſed in levelling, which is as follows: Suppoſe the height of the point A (plate LXXIX. *fig.* 15.) on the top of a mountain, above that of the point B at the foot thereof, be required. Place the level about the middle diſtance, between the two points, as in D, and ſtaffs in A and B; and let there be perſons inſtructed with ſignals for raiſing and lowering on the ſtaffs little marks of paſteboard, or any ſuch matter. The level being placed horizontally, &c. look towards the ſtaff AE, and cauſe the mark to be raiſed or lowered, till the middle, upper edge, or other moſt conſpicuous part, appear in the viſual ray. Then meaſuring exactly the perpendicular height of the point E above A, which ſuppoſe eight feet ſix inches, ſet that down in your book; then turn the level horizontally about, that the eye-glaſs of the teleſcope may be ſtill next the eye, when you look the other way; (if you have only plain ſights, the inſtrument need not be turned;) and cauſe the perſon at the ſtaff B to raiſe or lower his mark, till ſome conſpicuous part fall in the viſual ray, as at C: Then meaſure the perpendicular of C above B, which ſuppoſe twenty feet eight inches; ſet this alſo down in the book above the other number; ſubtract the one from the other, the remainder will be twelve feet two inches, which is the difference of level between A and B, or the height of the point A above B.

If the point D, where the inſtrument is fixed, be in the middle between A and B, there will be no neceſſity for reducing the apparent level to the true; the viſual ray being then equally raiſed above the true level.

If it be farther required to know whether there be a ſufficient deſcent for conveying water from the ſpring A to the point B; (*fig.* 16.) here, as the diſtance from A to B is conſiderable, it is requiſite that ſeveral operations be made. Having then choſen a proper place for the firſt ſtation, as at I, ſet up a ſtaff in the point A, near the ſpring, with a proper mark to ſlide up and down the ſtaff, as L; and meaſure the diſtance from A to I, which ſuppoſe 2000 yards. Then, the level being adjuſted in the point K, let the mark L be raiſed and lowered till you ſpy ſome conſpicuous part through the teleſcope, or ſights, and meaſure the height AL, which ſuppoſe thirteen feet five inches.

But, in regard the diſtance AI is 2000 yards, you muſt have recourſe to your table for reduction, ſubtracting eleven inches, which will leave the height AL twelve feet ſix inches; and this note down in your book. Now turn the level horizontally, ſo as the eye-glaſs of the teleſcope may be towards the ſtaff at A; and, fixing up another ſtaff at H, cauſe the mark G to be moved up and down, till you can ſpy ſome conſpicuous part: Meaſure the height HG; which ſuppoſe ſix yards, four feet, two inches: Meaſure likewiſe the diſtance of the points IH, which ſuppoſe 1300 yards, for which diſtance, four inches eight lines muſt be ſubtracted from the height HG, which will leave but ſix yards, three feet, nine inches, four lines, to be taken down in your book. This done, remove the level forwards to E, whence the ſtaff H may be viewed; as alſo another ſtaff at D: And proceed in every reſpect as before.

When a proper ſtation for the level has been pitched upon between the two points, the two heights obſerved at that ſtation muſt be written down in two columns, namely, under the firſt column thoſe obſerved when the eye was from the ſpring, or towards the point, which may be called back-ſights; and under the ſecond column thoſe obſerved when the eye was next the ſpring, or the fore-ſights.

Having ſummed up the height of each column ſeparately, ſubtract the leſſer from the greater, and the remainder will be the difference of level between A and B.

If the diſtance of the two points be required, add all the diſtances meaſured together, and, dividing the difference of height by the yards of the diſtances, for each 200 yards you will have a deſcent of about two inches nine lines.

Dr. Halley ſuggeſts a new method of levelling; which is performed wholly by the barometer, in which the mercury is found to be ſuſpended to ſo much the leſs height, as the place is farther remote from the center of the earth. Hence it follows, that the different height of the mercury in two places gives the difference of level.

Mr. Derham, from ſome obſervations at the top and bottom of the Monument in London, found that the mercury fell one tenth of an inch at every eighty two feet of perpendicular aſcent, when the mercury was at thirty inches: Dr. Halley allows of one tenth of an inch for every thirty yards; which, conſidering how accurately barometers are now made, he thinks this method ſufficiently exact to take levels for the conveyance of water, and leſs liable to errors than the common levels.

He alſo found a difference of three inches eight tenths between the height of the mercury at the top and bottom of Snowdon hill, in Wales.

the common occaſions of levelling, ſet a pole upright in a ſpring, pond, &c. and mark how many feet and inches are above water: Then ſet up another pole of

equal length with the other, in the place to which the water is to come. Place the center of a quadrant on the top of this laſt pole, the plummet hanging free; ſpy through the ſights the top of the pole in the water, and if the thread cuts any degree of the quadrant, the water may be conveyed by a pipe laid in the earth. If you cannot ſee from one extreme to the other, the operation may be repeated.

LEVER, in mechanics, is any inflexible line, rod, or beam, moveable about or upon a fixed point, called the prop or fulcrum, upon one end of which is the weight to be raiſed; at the other end is the power applied to raiſe it, at the hand, &c.

Since the momentum of the weight and power are as the quantities of matter in each multiplied by their reſpective celerities: and the celerities are as the diſtances from the center of motion, and alſo as the ſpaces paſſed through in a perpendicular direction in the ſame time; it muſt follow, that there will be an equilibrium between the weight and power, when they are to each other reciprocally as the diſtances from the center, or as the celerities of the motions, or as the perpendicular aſcent or deſcent in the ſame time; and this univerſally in all mechanical powers whatſoever, which is therefore the fundamental principle of all mechanics.

The general properties of the lever may be eaſily obtained by the ſolution of the following problem.

To determine the poſition in which the bended lever BDC, (plate LXXX. *fig.* 1.) whoſe center of motion is the point D, will be ſuſtained in equilibrio by means of two weights P, Q, appended to the ends P and Q of the ſtrings BKP, CIQ, faſtened to the extremities B and C of the lever, and paſſing freely over two ſmall pullies fixed in the points K, I.

Solution. Through any convenient point M, draw a horizontal line SMR, and let BDC repreſent the required poſition. Produce PK, QI, to the line SMR, and draw BT, DM, CN, parallel to PS, or QR; draw alſo BEW and CH parallel to SMR; join the points B, C, with a right line BC, and from D, draw DA perpendicular to BC. Put KS $=a$, DM $=b$, SM $=d$, BD $=m$, DC $=n$, BC $=h$, IR $=c$, MR $=e$, p and q for the ſine and coſine of the angle DBC, radius $=1$. Let L and l repreſent the lengths of the ſtrings BKP, CIQ, put TB $=x$; then will DE $=b-x$, BE $=\sqrt{m^2-b-x^2}$, and FB $=d-\sqrt{m^2-b-x^2}$; whence BK $=\sqrt{d-\sqrt{m^2-b-x^2}^2+\overline{a-x}^2}$, and conſequently PS $=L-\sqrt{d-\sqrt{m^2-b-x^2}^2+\overline{a-x}^2}+a$. Again, $\frac{b-s}{m}$ $=$ ſin. $\angle$DBE, and its coſine $=\frac{\sqrt{m^2-b-x^2}}{m}$; therefore $q\times\frac{b-x}{m}-\frac{p}{m}\times\sqrt{m^2-b-x^2}$, $=$ ſin. $\angle$WBC; whence NC $=qb\times\frac{b-x}{m}+x-\frac{pb}{m}\times\sqrt{m^2-b-x^2}$, and HI $=c-qb\times\frac{b-x}{m}+\frac{bp}{m}\times\sqrt{m^2-b-x^2}-x$. But by the elements of plane trigonometry, the product of the ſines of any two angles, added to that of their coſines, is equal to the coſine of their difference multiplied by radius; therefore $p\times\frac{b-s}{m}+q\times\frac{\sqrt{m^2-b-x^2}}{m}$ is the ſine of the angle BCW; hence EW $=pb\times\frac{b-s}{m}+qb\times\frac{\sqrt{m^2-b-x^2}}{m}-\sqrt{m^2-b-x^2}$, and CI $=$

$$\sqrt{c-qb\times\frac{b-x}{m}+bp\times\frac{\sqrt{m^2-b-x^2}}{m}-x}^2+\overline{e-pb\times\frac{b-s}{m}-qb\times\frac{\sqrt{m^2-b-x^2}}{m}\times\sqrt{m^2-b-x^2}}^2$$

Hence, by lemma 1. Clark's Introduction to Mechanics, the perpendicular diſtance of the common center of gravity of the two weights P, Q, from the horizontal line SR, will be expreſſed by

$$\frac{P\times L-P\times\sqrt{d-\sqrt{m^2-b-x^2}^2+\overline{a-x}^2}+P\times a+l\times Q-Q\times CI+Q\times c}{P+Q};$$ which, being put into fluxions, made $=0$, and the equation thence ariſing properly reduced, by firſt ſubſtituting therein for the values of $\frac{qb}{m}$ and $\frac{pb}{m}$, their reſpective equals, viz. $\frac{BA\times BC}{BD^2}$, and $\frac{AD\times BC}{BD^2}$, there will at length be produced the following equation: $\frac{P\times FB\times DE+P\times BE\times KF}{BE\times BK}+\frac{Q\times HI}{CI}+\frac{Q\times CH\times DE\times AB\times BC}{BD^2\times BE\times CI}-\frac{Q\times HI\times BA\times BC}{BD^2\times CI}=\frac{Q\times HI\times AD\times BC\times DE}{BD^2\times BE\times CI}$.

Corol 1. If FB and HC are each equal to 0, we ſhall have $P+Q=Q\times\frac{BA\times BC}{BD^2}+\frac{Q\times AD\times BC\times DE}{BD^2\times BE}$.

Corol 2. If FB, CH, and AD, are each equal 0, the general equation will contract into $AB\times P=AC\times Q$, or P : Q :: AC : AB, A in this caſe being the center of motion.

Corol 3. If, from the center of motion D, we let fall DL perpendicular upon BK, and DN perpendicular upon IC produced, then will $P\times DL=Q\times DN$; whence P : Q :: DN : DL.

The lever is of five kinds. The common ſort where the prop is between the weight and the power, but nearer the former. When the prop is at one end, the power applied at the other, and the weight between both. When the prop is at one end, the weight at the other, and the power applied between both. The bended lever which differs only in form from the firſt ſort. When the prop is placed at an equal diſtance between the weight and the power, and this is commonly called the balance. See BALANCE.

LEVERET, among ſportſmen, denotes a hare in the firſt year of her age.

LEVIGATION, in pharmacy and chemiſtry, the reducing hard bodies to an impalpable powder, by grinding them with water on a porphyry, or marble.

LEVITE, in a general ſenſe, means all the deſcendants of Levi, among whom were the Jewiſh prieſts themſelves, who, being deſcended from Aaron, were likewiſe of the race of Levi: but it is more particularly uſed for an order of officers in that church, who were employed in performing the manual ſervice of the temple, ſuch as in fetching wood, water, and other things neceſſary for the ſacrifices; and in ſinging and playing upon inſtruments of muſic.

LEVITICUS, a canonical book of the Old Teſtament, ſo called from its containing the laws and regulations relating to the prieſts, Levites, and ſacrifices.

The ſeven firſt chapters of this book preſcribe the ceremonies to be obſerved in offering burnt-ſacrifices, meat-offerings, peace-offerings, &c. then Moſes relates in what manner the prieſts were to be conſecrated, and the misfortune of Nadab and Abihu, who offered incenſe to the Lord with ſtrange fire. Upon this occaſion, he preſcribes ſome laws concerning the mourning of the prieſts, and forbids their drinking wine, while they were employed in the ſervice of the tabernacle. In the eleventh, twelfth, thirteenth, and fourteenth chapters, he lays down rules for diſtinguiſhing clean and unclean beaſts, and concerning the leproſy, purifications, &c. appoints the ceremonies to be obſerved upon the great day of expiation: regulates the degrees of kindred within which perſons were allowed or forbidden to marry: prohibits alliances with the Canaanites, and alſo idolatry, theft, perjury, calumny, &c. In the twenty-third chapter, he takes notice of the principal annual feſtivals, the paſſover, pentecoſt, &c. preſcribes what was to be obſerved in the ſabbatical and jubilee-years, and concludes with regulations concerning vows and tythes.

5 JA 59

LEVITY, in phyſiology, the privation or want of weight in any body, when compared with another that is heavier than it, in which ſenſe it ſtands oppoſed to gravity. See the articles GRAVITATION and GRAVITY.

LEVY, in law, ſignifies to gather or collect, as to levy money; and to levy a fine of lands, is the paſſing a fine.

LEX, LAW. See the article LAW.

LEXICON, the ſame with dictionary. It is generally uſed in ſpeaking of Greek dictionaries.

The word is Greek, λεξικον, and derived from λεξις, a word.

LIBATION, a religious ceremony among the ancient pagans, which conſiſted in an effuſion of liquors poured on the head of the victims prepared for ſacrifice.

Libations were alſo in uſe among the Hebrews, who poured a tun of wine on the victim after it was killed, and the ſeveral pieces of the ſacrifice were laid on the altar, ready to be conſumed in the flames.

LIBEL, injurious reproaches or accuſations againſt a perſon, written and publiſhed in order to expoſe him to public contempt, hatred, or ridicule.

LIBEL, in the law of Scotland, implies an indictment. See INDICTMENT.

LIBELLA, or LIBELLULA, in the hiſtory of inſects, a genus of four-winged flies, called in Engliſh dragon-flies, or adder-flies; the characters of which are, that they are furniſhed with jaws, the antennæ are ſhort, and the tail terminated by a kind of forceps.

LIBERATE, in law, a writ that lies for the payment of a penſion, or annual ſum, granted under the great ſeal, being directed to the treaſurer and chamberlains of the exchequer.

LIBERIA, in Roman antiquity, a feſtival obſerved on the ſixteenth of the calends of April, at which time the youth laid aſide their juvenile habit for the toga virilis, or habit peculiar to grown men. See the article TOGA.

LIBERTUS, in Roman antiquity, a perſon who from being a ſlave had obtained his freedom. See MANUMISSION.

LIBERTY, *Libertas*, in general, denotes a ſtate of freedom, in contradiſtinction to ſlavery. See the article FREEDOM.

According to Cicero, liberty is the power of living as a man pleaſes, or without being controlled by another.

In a legal ſenſe, liberty ſignifies ſome privilege that is held by charter or preſcription.

LIBRA, the ballance, in aſtronomy, one of the twelve ſigns of the zodiac, the ſixth in order; ſo called becauſe, when the ſun enters it, the days and nights are equal, as if weighed in a ballance.

LIBRA, in Roman antiquity, a pound weight; alſo a coin, equal in value to twenty denarii.

LIBRARY, an edifice, or apartment, deſtined for the placing of books; or the books themſelves lodged therein.

The word is formed from the Latin *libraria*, which is derived from *liber*, a book.

LIBRATION, in aſtronomy, an apparent inequality in the motion of the moon, by which ſhe ſeems to librate or waver about her own axis, ſometimes from the eaſt to the weſt, and ſometimes from the weſt to the eaſt. See the article MOON.

LIBRATION *of the Earth* is that motion whereby the earth is ſo retained in its orbit, that its axis continues conſtantly parallel to the axis of the world.

LICENCE, in law, an authority given to a perſon to do ſome lawful act.

LICENTIATE, one who has obtained the degree of licence.

LICHEN, *Cinereus Terreſtris*, aſh-coloured ground liver-wort, in botany, a ſpecies of moſs, conſiſting of roundiſh, pretty thick leaves, divided about the edges into obtuſe ſegments, flat above, of a reticular texture underneath, faſtened to the earth by ſmall fibres; when in perfection, of an aſh-grey colour; by age, turning darker-coloured or reddiſh. It grows on commons and open paths, ſpreads quickly on the ground, and is to be met with at all times of the year, but is ſuppoſed to be in its greateſt vigour about the end of autumn.

This herb is ſaid to be a warm diuretic. It is particularly celebrated as a preſervative againſt the terrible conſequences of the bite of a mad dog: an account of the remarkable efficacy, in this intention, of a powder compoſed of the dry leaves and black pepper, was communicated to the Royal Society by Mr. Dampier, and publiſhed in N°. 237 of the Philoſophical Tranſactions. This powder was afterwards inſerted, in the year 1721, into the London Pharmacopœia, at the deſire of Dr. Mead, who had large experience of its good effects, and who declares, that he had never known it to fail, where it had been uſed, with the aſſiſtance of cold bathing, before the hydrophobia began.

LICTORS, *Lictores*, in Roman antiquity, the ſerjeants or beadles who carried the faſces before the ſupreme magiſtrates: it was alſo a part of their office to be the public executioners in beheading, ſcourging, &c.

LIEGE, in law, a term ſometimes uſed for liege-lord, or one who owns no ſuperior; and ſometimes for liege-man, or one who owes allegiance to the liege-lord. In our ſtatutes, the king's ſubjects are ſometimes called lieges, or liege-people.

LIEN, the ſpleen, in anatomy. See SPLEEN.

LIENTERY, in medicine, a diſorder proceeding from a preternatural ſmoothneſs of the inteſtines, in conſequence of which what is diſcharged by ſtool, greatly reſembles the aliments, both in colour and ſubſtance.

The cauſe of this diſorder, according to Fernelius, is not an obſtructed or hindered diſtribution of the aliments, but a weakneſs of the firſt concoction, in conſequence of which the aliments paſs through the inteſtines unchanged.

The principal intention of cure in a lientery, according to Etmuller, is to ſtrengthen and corroborate the ſtomach; which end is moſt effectually obtained by rhubarb, preparations of coral, and quinces. All the medicines recommended againſt vomiting, are alſo proper in this diſorder. Waldſchmidius informs us, that the moſt ſimple and eaſily prepared ſtomachics are more beneficial in a lientery, than thoſe of the compound kind. The moſt proper ſtomachics, according to that author, are preſerved nutmeg, preſerved ginger, the white of an egg boiled with vinegar, and wormwood-wine prepared with maſtich.

LIEUTENANT, an officer who ſupplies the place, and diſcharges the office of a ſuperior in his abſence. Of theſe, ſome are civil, as the lords-lieutenants of kingdoms, and the lords lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-general of the artillery, lieutenant-colonel, lieutenant of the artillery of the tower, lieutenant of horſe, foot, ſhips of war, &c.

Lord LIEUTENANT *of Ireland* is properly a viceroy, and has all the ſtate and grandeur of a king of England, except being ſerved upon the knee. He has the power of making war and peace, of beſtowing all the offices under the government, of dubbing knights, and of pardoning all crimes except high treaſon; he alſo calls and prorogues the parliament, but no bill can paſs without the royal aſſent. He is aſſiſted in his government by a privy-council; and on his leaving the kingdom, he appoints the lords of the regency, who govern in his abſence.

Lords LIEUTENANTS *of Counties* are officers who, upon any invaſion or rebellion, have power to raiſe the militia, and to give commiſſions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lords-lieutenants are deputy-lieutenants, who have the ſame power; theſe are choſen by the lords-lieutenants, out of the principal gentlemen of each county, and preſented to the king for his approbation.

LIEUTENANT-GENERAL is an officer next in rank to the general; in battle, he commands one of the wings; in a march, a detachment, or a flying camp; alſo a quarter, at a ſiege, or one of the attacks, when it is his day of duty.

LIEUTENANT *of a Ship of War*, the officer next in command to the captain, and who governs the ſhip in his abſence.

In the Britiſh navy an officer muſt have ſerved ſix years at ſea, two of which he muſt have been mate or midſhipman in ſome of the king's ſhips, before he can be appointed a lieutenant; he muſt alſo paſs an examination.

The number of lieutenants appointed to a ſhip is always in proportion to her rate, a firſt rate having ſix, and a ſixth rate only one.

In an engagement the ſtation of the lieutenants is to ſuperintend the manoeuvre of the great guns, and obſerve that they are properly ſupplied with powder and ſhot, &c. The lieutenant ranks with captains of horſe and foot.

LIFE, *Vita*, in general, a kind of active operative exiſtence, and conceived to conſiſt in motion.

LIFE is uſed in a more particular ſenſe to ſignify the duration of an animal's being; or the ſpace of time which paſſes between its birth and death.

LIFE-ANNUITIES. See the article INTEREST.

LIFTS, in the ſea-language, certain ropes which reach from the maſt-heads to the yard-arms of a ſhip, to keep the ſail-yards parallel to the deck, or as ſeamen term it, ſquare by the lifts, i. e. parallel to the horizon, when the ſhip is upright, or at right angles with the maſt.

The lifts are alſo employed to top the yards, i. e. to lift one yard-arm higher than the other, by drawing in one lift, and ſlackening the other.

Topping-LIFT. See TOPPING-*Lift*.

LIGAMENT, in anatomy, a ſtrong compact ſubſtance, ſerving to join two bones together.

A ligament is more flexible than a cartilage, not eaſily ruptured or torn, and does not yield, or at leaſt very little, when pulled.

Some ligaments are deſigned to ſtrengthen the joints, and to ſecure the bones in their ſeveral motions from parting from each other, as happens in luxations; other ligaments ſerve to connect cartilages with bones; and ſome there are which ſtrengthen other parts, beſides the bones and cartilages: of this laſt kind are the annular ligaments, ſo called, not ſo much from their figure as from their uſe, ſerving, like a ring, to bridle the tendons of many muſcles. Some ligaments again are fixed to one or more bones, with different degrees of tenſion, and ſerve on each ſide for the inſertion of muſcles. To theſe may be added, the ligaments commonly termed aponeuroſes; ſuch as thoſe of the temples, ſcapula, or humeri, ulna, palm of the hand, thigh, leg, and ſole of the foot. Other differences of ligaments may be deduced from their conſiſtence, ſolidity, ſituation, and figure; ſome are almoſt cartilaginous, and others have a particular elaſticity, by which they are capable of being drawn out by a ſufficient force, and of contracting again when left to themſelves.

LIGATURE, in ſurgery, is a cord, band, or ſtring; or the binding any part of the body with a cord, band, fillet, &c. whether of leather, linen, &c.

Ligatures are uſed to extend and replace bones that are broken or diſlocated; to tie the patients down in lithotomy and amputations; to tie upon the veins in phlebotomy, or the arteries in amputations, or in large wounds; to ſecure the ſplints that are applied to fractures; to tie up the proceſſes of the peritonæum, with the ſpermatic veſſels in caſtration; and laſtly, in taking off warts or other excreſcences by ligature. For the manner of uſing them, ſee LITHOTOMY, PHLEBOTOMY, FRACTURE, &c.

LIGHT, *Lux*, in philoſophy, certain inconceivable ſmall particles of matter of different magnitudes, which are emitted or reflected from every point in the ſurface of a luminous body in right lines, and in all directions, with an unparalleled velocity, and whoſe power and intenſity decreaſe as the ſquares of the diſtances increaſe.

The Greeks, and after them all the barbarous nations, who learned of them to reaſon and to err, have ſaid from age to age through a long ſeries of time, "Light is an accident, which accident is the act of tranſparent as tranſparent; colours are what move tranſparent bodies. Luminous and coloured bodies have qualities like thoſe they excite in us, according to the maxim that nothing can give what it has not. In fine, light and colours are a mixture of the hot, cold, dry, and humid; for the humid, dry, cold, and hot, being the principles of all things, colours muſt neceſſarily be compoſed of them." See the article COLOUR.

This is the abſurd jargon which the profeſſors of ignorance, paid by the public, have made human credulity revere ſo many eges; which manner of reaſoning prevailed almoſt in all things down to the time of Galileo and Deſcartes. Even long after them, the ſame traſh, the diſgrace of human underſtanding, ſubſiſted in many ſchools.

All the pretended philoſophers therefore having gueſſed of nature at a venture through the veil under which ſhe lay concealed, Deſcartes at length came, and diſcovered a corner of this great veil. He ſaid, "Light is a fine and ſubtile matter, diffuſed univerſally, that ſtrikes our eyes. Colours are ſenſations excited in us by God, according to the motions which tranſmit that matter to our organs." Thus far Deſcartes was in the right, and ought either to have ſtopped there, or, in advancing, to have taken experiment for his guide. But he was poſſeſſed with the deſire of eſtabliſhing a ſyſtem. That paſſion had the ſame effect on this great man, as paſſions have on all men; they hurry them beyond their principles.

According to Deſcartes, the light does not proceed to our eyes from the ſun, but is a globulous matter diffuſed univerſally, which the ſun impels, and which preſſes upon our eyes as a ſtaff puſhed at one end preſſes the ſame inſtant at the other. This appeared plauſible, but is not therefore the leſs falſe. Deſcartes, however, was ſo fully convinced of this principle, that, in his ſeventeenth letter of the third volume, he poſitively ſays and repeats it, "I confeſs that I know nothing of philoſophy, if the light of the ſun is not tranſmitted to our eyes in an inſtant." And indeed we muſt own, that, as great a genius as he was, he knew very little of true philoſophy, and wanted the experiments of the preceding age. That age is as much ſuperior to Deſcartes, as Deſcartes was to antiquity.

If light were always diffuſed, and always exiſting in the air, we ſhould ſee as clearly in the night as we do in the day; becauſe the ſun below the horizon would continually impel the globules on all ſides, and the impreſſion equally affect our eyes.

That light is a material ſubſtance, and what we properly call body, is not to be doubted; becauſe we find it ſomething that has motion, or is propagated in time; ſomething that acts upon our bodies, and produces great alterations and changes in their natures and forms. It is ſomething that bodies act upon, by reflecting, inflecting, and refracting it on their ſurfaces, and in their pores: and it would appear to have weight, and all other ſenſible qualities of common matter, were it not that the ſmallneſs of its quantity renders them entirely imperceptible to us. Nor are we to conſider light only as a body, but as the moſt active principle or moſt general agent in nature; and it is, perhaps, the true primum mobile, or the ſpring of motion and action in all other bodies. Were the particles of light to be annihilated, we ſhould ſee no marks or foot-ſteps of fire or heat remaining, and therefore no power of motion in bodies; but all things would put on the appearance of lifeleſs inert matter, rigid and inflexible, as it would be abſolutely cold and dark.

The divine wiſdom and providence appear, perhaps, in nothing ſo remarkably as in the extreme ſubtility of the particles of light: without this qualification it could not have pervaded the pores of bodies, and ſo we could have had none of thoſe which we call diaphanous or tranſparent ſubſtances, and every thing but the ſurface of a body would have been concealed from the ſight of mankind. Again, the velocity of a body is always as the quantity of matter inverſely; and therefore, the ſmaller the body, the greater velocity it is ſuſceptible of from the ſame force; whence it comes to paſs that light is the qualified to be tranſmitted through immenſe diſtances in a ſmall and inſenſible part of time; which thing was quite neceſſary, according to the preſent frame and ſtate of nature.

But laſtly, it was abſolutely neceſſary that the particles of light ſhould be ſo exceeding ſmall, that, when compounded with its velocity, it ſhould produce no ſenſible force, as it muſt otherwiſe have done, and which, therefore, could not have been borne by the tender and delicate texture of the ſeveral parts of vegetable and animal bodies. To give an example: the velocity of a particle of light is found to be at the rate of 897600000 feet in a ſecond; ſuppoſe its matter to be but one millionth part of a grain, then its force to ſtrike an object would

as $\frac{2.7.6.8.8.8.}{1.0.0.0.0.0.} = 897,6$ feet per ſecond for one grain; or it would ſtrike with the ſame force that one grain weight would do falling from half the height, viz. through 448,8 feet; which we ſhould find to be very great, was the experiment to be made on the ſenſible coats of the eye.

Since the weight of bodies is proportional to the quantity of matter, it follows, that, where the latter is diminiſhed indefinitely, the former will be ſo too; therefore, the weight of light muſt be inſenſible to ever ſo great a quantity of it. Dr. Boerhaave cauſed a globe of iron, twelve inches in diameter, to be heated red-hot, and ſuſpended at the end of a very exact ballance, and counterpoiſed by weights at the other end very nicely, and thus let it hang till all the particles of heat or light were eſcaped, when he found the equilibre of the ballance no ways altered; which plainly proves the above theſis. See the article FIRE.

That the particles of light have not only magnitude, but that in different degrees alſo, is another, and perhaps the moſt ſubtile, diſcovery of the Newtonian philoſophy. The comparative terms of greater and leſſer are now as applicable to the particles of light, as to any other bodies. This is abſolutely proved by the different refrangibility they are found to have in paſſing through a priſmatic figure of glaſs or water; for the power of the priſm detains the iſſuing particle, and draws it a little towards the ſurface; and, ſince this power is the ſame, it would have the ſame effect on all the particles of light, if they were all of an equal magnitude, becauſe they have all an equal velocity. But ſince this effect is different among the particles, ſome being detained and drawn aſide to a greater diſtance than others, it follows, they muſt be leſs in magnitude, to become more ſubject to the influence of the attracting ſurface; in like manner as the electric effluvia will act upon and agitate very ſmall and light bodies, much ſooner and more eaſily than they can move thoſe which are larger. But of this more when we come to ſpeak of the manner in which this power acts in refracting the rays of light. See REFRACTION.

If light were not reflected from every point in the ſurface of a body in all directions every way, there might be aſſigned a point of ſpace where a ray of light, from ſuch a point in the ſurface, does not come; and there the ſaid point of the ſurface could not be viſible: but becauſe the eye can find no point of ſpace in all the viſible hemiſphere reſpecting that point, but where it is viſible; therefore a ray of light is reflected from that point to every part of ſpace, from whence a right line to that point can be drawn.

That the rays of light proceed in a right-lined direction, is evident from hence, that whatever the figure of the body be, if it be held perpendicular to the rays of light, it will always caſt a ſhadow of the ſame figure againſt a parallel plane. Thus a circle will produce a circular ſhadow, a triangle a triangular one, and ſo on. Which plainly ſhews that the rays of light paſs by the extremities of theſe bodies in right-lined directions, excepting theſe only which paſs contiguous to the edges of the body; for they will be a little inflected, which will cauſe the extremity of the ſhadow to be not ſo diſtinct and well defined as it otherwiſe would be; of which we ſhall take farther notice hereafter.

As all the other affections of light, ſo that of its velocity was utterly unknown to all the ancient, and moſt of the modern philoſophers, who, before the time of Mr. Romer, were of opinion that the motion of light was inſtantaneous, or that it was propagated through immenſe ſpaces in an inſtant. But Mr. Romer, and other philoſophers, about this time, making frequent obſervations on the eclipſes of Jupiter's moons, found that the time of theſe eclipſes did not correſpond to the calculations founded upon the aſtronomical tables; where the times are all calculated for the diſtance of the center of the ſun, and conſequently where the eye of the ſpectator muſt be ſuppoſed to be in viewing the ſaid eclipſes, occultations, &c. of Jupiter's moons.

To illuſtrate this matter, let S (plate LXXX. *fig.* 2.) be the center of the ſun, A B the orbit of Mercury, C D the orbit of Venus, E F that of the earth, and G H a part of the orbit of Jupiter. Let I be the body of Jupiter, and K L its ſhadow; O M N the orbit of one of Jupiter's moons, M juſt entering the ſhadow of Jupiter. Now a ſpectator at S would obſerve the moon M to enter the ſhadow, juſt at the time which is calculated from the tables: but a ſpectator on the earth, at T, always obſerves it to happen ſooner; and, when the earth is in the oppoſite part of its orbit R, he will always obſerve it to happen later, by the ſpace of about ſeven minutes, in both caſes. This obſervation gave the firſt proof that light was progreſſive, and took up about fourteen minutes to paſs over the diameter of the earth's orbit from T to R, or ſeven minutes to paſs from the ſun S to the earth T.

But this, though a ſufficient diſcovery or proof of the progreſſive motion of light, was yet but an experiment in the groſs, and not accurate to determine or define the true rate of velocity which properly belonged to light: the ſolution of this noble problem was reſerved for Dr. Bradley, who by reiterated and certain experiments, obſerved, that the bright ſtar in the head of Draco appeared 39″ more northerly in September than in March, juſt the contrary way to what it ought to appear by the annual parallax of the ſtars, which muſt ariſe from the velocity of light bearing ſome proportion to that of the annual motion of the earth. See the article ABERRATION *of the Stars*.

To illuſtrate this, and from thence to determine the velocity of light: let A B (*fig.* 3.) repreſent a part of the earth's annual orbit, and let C be a ſtar obſerved by a ſpectator at the earth at A; when the earth arrives at B, the ſtar will not be obſerved at C, as before, but at D in the line B D parallel to A C; for let A B be divided into equal parts A *a*, *ab*, *bc*, *cd*, and *d* B; then through theſe points draw the lines *ae*, *bf*, *cg*, *dh*, parallel to A C and D B. Now let the velocity of the earth be to that of the light as A B to C B. When the earth ſets out from the point A, ſuppoſe the ray of light commences its motion from the ſtar at C in the direction C B perpendicular to A B; then it is plain, when the earth is arrived at *a*, the particle of light will be got to *i*, the point where *a e* cuts B C, and the ſtar will be ſeen in the direction *a i*, and appear at *e*. In like manner, when the earth is at *b*, the particle of light will be come to *k*, and will appear at *f*; and ſo on; when the earth is at *c*, *d*, B, the particle will be at *l*, *m*, and B, and the ſtar will appear at *g*, *h*, and D. If therefore the line C A repreſents the axis of a teleſcope, making the angle B A C with the direction of the earth's motion A B; when the ſpectator comes to B, he will ſee the ſtar at D, which he could not do, if the teleſcope was directed in the perpendicular line B C; but the difference of the poſitions of the lines D B and B C, or the angle D B C, is ſo very ſmall as to amount to no more than 20″ 15‴, which gives the proportion of the ſides B C to C D or A B, as 10210 to 1; which ſhews that the velocity of light is 10210 times greater than the velocity of the earth in her orbit. But the velocity of the earth is known, which is about 500,000,000 miles in 365 days, or about 56,000 miles per hour; whence the velocity of light will be found to be ſuch as carries it through the ſpace of 170,000 miles, or 897,600,000 feet in one ſecond; and, therefore, it will paſs from the ſun to us in 8′ and 13″.

If a cannon will throw a ball one mile perpendicular height, or 5280 feet, the velocity with which it goes from the cannon's mouth is the uniform velocity of 10,560 feet per 18 ¼″, which is the time of the perpendicular aſcent or deſcent, and therefore the velocity of the cannon-ball is 578 feet per ſecond. Whence the velocity of light is, to that of the cannon-ball, as 897,600,000 to 578, or as 1,550,000 to 1, nearly.

The doctor found that the parallax of the fixed ſtars, inſtead of amounting to many ſeconds, as ſome have deduced from their obſervations, does not make one ſecond; and from thence it follows that the abovementioned ſtar, in draco, is about 400,000 times farther from us than the ſun; and, conſequently, that the light takes up above 493″ × 400,000 = 197,200,000 ſeconds, which is more than ſix years, in coming from that ſtar to us.

For the properties of reflected and refracted light, ſee the articles REFLECTION and REFRACTION.

LIGHT is alſo uſed to denote the diſpoſition of objects,

with regard to the receiving of light: thus, the doors, windows, &c. of houſes, are called lights.

For the lights and ſhades of paintings, &c. ſee CLARO-OBSCURO.

LIGHTER, a ſort of veſſel or large boat employed in harbours or rivers, particularly the Thames, to bring goods to and from a ſhip in the act of lading and delivering the cargo. See CARGO.

LIGHT-HOUSE, among ſailors, a little houſe erected on a cape, hill, or promontory, near the ſea-coaſt, for the direction of ſhips which are paſſing that way: for this purpoſe it is furniſhed with great lights at the top, and has always ſomebody to watch them. As the lights may be ſeen at a great diſtance, they are very ſerviceable in guiding ſhips which are at a loſs to know where they are.

LIGHTNESS, or *Levity of* BODIES. See the article LEVITY.

LIGHTNING, in phyſiology, the burſting of fire from a cloud.

From Mr. Franklin's experiments, it appears, that lightning is only electrical fire drawn off from the clouds; and, in effect, this electricity has been collected during thunder in iron bars, or on tin-tubes, in many parts of Europe. See ELECTRICITY.

Thunder then, or lightning, is in the hand of nature, what electricity is in ours; the wonders which we now exhibit at pleaſure, are only little imitations of thoſe great effects which frighten us. A cloud prepared by the action of winds, by heat, by a mixture of exhalations, &c. is the electrified body; and watery clouds, or terreſtrial matter, the non-electrics which excite it. See the article THUNDER.

LIGULATED, among botaniſts, an appellation given to ſuch floſcules as have a ſtraight end turned downwards, with three indentures, but not divided into ſegments.

LIGUSTICUM, lovage, in botany, a genus of plants, the general corolla of which is uniform, and the ſingle flowers conſiſt each of five lanceolated petals, bent inwards at the points: the fruit is naked, oblong, angulated, ſulcated, and ſeparable into two parts; and containing two oblong, ſmooth ſeeds, plain on one ſide, and ſtriated on the other.

LIGUSTRUM, privet, in botany, a genus of trees, with a funnel-faſhioned flower, quadrifid or quinquifid at the limb: the fruit is a globoſe, ſmooth berry, with only one cell, containing four ſeeds, convex on one ſide, and angulated on the other.

LILAC, in botany, a genus of trees, otherwiſe called ſyringa. See SYRINGA.

LILIACEOUS, an appellation given to ſuch flowers as reſemble that of the lily. See LILY.

LILIO-FRITILLARIA, a ſpecies of fritillary. See FRITILLARY.

LILIO-HYACINTHUS, a ſpecies of ſcilla or quill. See SCILLA.

LILIO-NARCISSUS, or AMARYLLIS, in botany, a genus of plants, with a liliaceous flower, compoſed of ſix petals. Its fruit is a ſuboval capſule, with three cells, containing a great many ſeeds.

LILIUM, the lily. See LILY.

LILIUM *Convallium*, lily of the valley. See CONVALLIUM *Lilium*.

LILY, *lilium*, in botany, the name of a large genus of plants, with a kind of bell-faſhioned flower, and is compoſed of ſix leaves, which are more or leſs expanded and bent back. The piſtil ſtands in the center of the flower, and finally becomes an oblong and trigonal fruit, which is divided into three cells, and contains a number of marginated ſeeds, arranged in a double order one on another. To this muſt be added, that the root is of a bulbous form, and is compoſed of a number of fleſhy ſcales affixed to an axis.

All ſorts of lilies and martagons are propagated by ſowing their ſeeds; and if the ſeeds are carefully ſaved from good flowers, the martagons very frequently afford very beautiful varieties.

The manner of ſowing them is this: ſome ſquare boxes ſhould be provided of about ſix inches deep, with holes bored in the bottoms to let out the wet; theſe muſt be filled with freſh light ſandy earth, and the ſeeds muſt be ſown on them pretty thick in the beginning of Auguſt, ſoon after they are ripe, and covered over about half an inch deep with light ſifted earth of the ſame kind. They ſhould be then placed where they may have the morning ſun; and if the weather prove dry, they muſt be watered at times, and the weeds carefully picked out. In the month of October, the boxes are to be removed to a place where they may have as much ſun as poſſible, and be ſecured from the north and north-eaſt winds. In ſpring the young plants will appear, and the boxes are then to be removed into their former ſituation; they ſhould be watered at times during the ſummer, and in Auguſt the ſmalleſt roots are to be emptied out of theſe boxes, and ſtrewed over a bed of light earth, and covered with about half an inch depth of light earth ſifted over them; they muſt here be watered and ſhaded at times, and defended from the ſeverity of the winter, by a light covering of ſtraw, or peaſe-haulm, in the hardeſt weather. In February the ſurface of the bed ſhould be cleared, and a little light earth ſifted over it. When the leaves are decayed, the earth ſhould be a little ſtirred over the roots, and in the month of September following a little earth ſifted on. In the September of the following year, the roots muſt be tranſplanted to the places where they are to remain, and ſet at eight inches diſtance, the roots being placed four inches below the ſurface: this ſhould be done in moiſt weather. They will now require the ſame care as in the preceding winters; and the ſecond after they are tranſplanted, the ſtrongeſt roots will begin to flower. The fine ones ſhould then be removed at the proper ſeaſon into flower-beds, and planted at great diſtances from one another, that they may flower ſtrong. *Miller's Gard. Dict.*

The roots of the white lily are emollient, maturating, and greatly ſuppurative. They are uſed externally in cataplaſms for theſe purpoſes with ſucceſs. The common form of applying them is boiled and bruiſed; but ſome prefer the roaſting them till tender, and then beating them to a paſte with oil, in which form they are ſaid to be excellent againſt burns. Gerard recommends them internally in dropſies.

LIMB, in a general ſenſe, denotes the border or edge of a thing: thus we ſay, the limb of a quadrant, of the ſun, of a leaf, &c.

LIMB, in anatomy, an appellation given to the extremities of the body, as the arms and legs. See ARM and LEG.

LIMBERS, or LIMBER-HOLES, in ſhip-building, ſmall holes in the lower part of the timbers of a ſhip cloſe to the keel; the purpoſe of which is to let the water, which may have come in by a leak, have a free paſſage to the well, where the pumps are fixed to draw it out: for this purpoſe every floor-timber is fitted with two of theſe, viz. one on each ſide of the kelſon.

LIMBER-BOARDS, ſhort pieces of plank which form a part of the ceiling of a ſhip's floor cloſe to the kelſon, and immediately above the timber-holes: they can be occaſionally removed to clear the limbers, when they are filled or clogged with any filth, ſand, gravel, &c.

LIME, *Calx*, a ſoft, friable ſubſtance, obtained by calcining or burning ſtones, ſhells, and the like.

There are ſo many ſpecies of ſtone capable of being burnt into lime, and ſo many that in the different parts of the world are really put to that uſe, that it would be difficult to affix any particular idea to the term lime-ſtone; but we are to underſtand by it in general, any ſtone, that upon a proper degree of heat, continued a ſufficient time, becomes a white calx, which will make a great ebullition and noiſe on being thrown into water, and will, in fine, fall into a looſe white powder at the bottom of that liquor; after having very ſtrongly impregnated it with its ſoluble particles. The moſt common kind of lime-ſtone is a greyiſh or bluiſh ſtone, found in looſe maſſes, and often veined with red: marble, alabaſter, and all the ſtones that have ſpar for their baſis, may alſo come under the general denomination of lime ſtone, ſince they all burn into lime. In general, every ſtone, of whatever kind or colour, that will ferment with aqua-fortis, will alſo burn into lime; and it is of no conſequence to the medicinal uſe of that calx, whether it be made of the one or the other of theſe ſtones. What lime we have in London is

is made of chalk, which is weaker than that made of ſtone; but it is otherwiſe the ſame.

The kilns uſed for making lime, are commonly built in a large pit; they are wide at the top, and grow narrow by degrees, as they approach nearer to the bottom: on the outſide, near the bottom of the kiln, there is a door, at which the aſhes are taken out, and juſt above that an iron-grate: upon this is placed a layer of ſtone, or whatever elſe is to be burnt for making lime, and upon that a layer of wood or coals, which is repeated till the kiln is full, only obſerving, that the outermoſt layer muſt be wood or coals. Chalk is commonly burnt in twenty-four hours, but ſtone often takes up ſixty hours: ten buſhels of ſea-coal, or a hundred of faggots three feet long, will burn forty buſhels of chalk, and forty buſhels of chalk will yield thirty buſhels of unſlacked lime.

The beſt lime is that made of the hardeſt ſtone; it is not only uſed by architects, builders, plaſterers, dyers, ſugar-refiners, tanners, and many other mechanics, but is an excellent manure for land, where it is ſandy, or a mixed gravel or clay ſoil. In many places it is carried out and laid in heaps, allowing a buſhel to a pole ſquare, or 160 buſhels to an acre.

The beſt method of ordering it, is to mix it with dung, or with mud drawn from the bottom of rivers: this makes an excellent mixture, eſpecially where the ſoil is ſandy; and in Weſtmoreland they produce fine crops of barley from their ſandy lands, by manuring them with lime and cow dung mixed together. The nature of lime on land is like that of chalk, it works downwards as the farmers expreſs it; and therefore it is beſt to treat it in the ſame manner, laying it fallow the year before it is to be ploughed up. It is obſerved that if the lime be carried hot out of the kiln, and laid upon the land to cool, it does much better than in any other way.

The improvement it makes upon land is owing chiefly to its heat, and the ſalt it contains. It is in much the ſame manner that coal aſhes and the ſoot of coal become uſeful upon the like kind of lands; but the farmers always find that a mixture of good earth and lime, that has laid a conſiderable time together, is better for this purpoſe than freſh lime alone.

Lime is alſo of great utility in medicine, for which uſe it is to be choſen in clean, light, and hard pieces, but not ſtony, ſuch as will not eaſily crumble to pieces between the fingers, and yet will readily break when thrown into water. The beſt lime in the world, on being long expoſed to a damp air, will moulder into a powder, and loſe all its medicinal virtues. Lime in its perfect and unaltered ſtate, as newly taken from the kiln, is called calx viva, or quick-lime: that which has lain in the air till it has fallen into powder, is called calx extincta; and that which has been thrown into water, and the powder it has fallen into afterwards waſhed with ſeveral freſh waters, is called calx lota.

Quick lime is burning and corroſive, and is never given internally; but it is ſometimes uſed in external applications, as made into a paſte with orpiment, ſoap, &c. and uſed as a depillatory. The calx lota is no longer a corroſive, but a powerful deſiccative; and lime-water is of great ſervice internally in all cutaneous eruptions, in the cure of obſtinate ulcers, and for diſeaſes of the lungs: for this purpoſe it is generally to be continued a conſiderable time.

The preparations of lime in uſe in the ſhops are, the ſimple lime-water; the leſs compound lime-water; the more compound lime-water; and ſeveral kinds of cauſtics, which ſee under the article CAUSTIC.

Simple lime-water is made in the following manner: Put a pound of quick-lime into a large earthen pan; pour upon it, by a little at a time, a gallon and a half of water; after the ebullition is thoroughly over, let the liquor ſtand to ſettle, and then pour it clear off, and filter it for uſe. This is principally intended for waſhing old ulcers, and other external purpoſes; when it is to be taken internally, the following additions are made to it, to take off its flavour, or to add to its virtues. Take of liquorice-root, an ounce; of ſaſſafras-bark, half an ounce; ſimple lime-water, three quarts; let the whole infuſe together for two days without heat, then filter it for uſe: this laſt preparation is called the leſs compound lime-water. The more compound lime-water is made thus: Take raſpings of guaiacum, half a pound; liquorice-root, an ounce; ſaſſafras-bark, half an ounce; of coriander-ſeed, three drams; of lime-water, three quarts; let the whole ſtand together two days without heat, and then filter it off for uſe.

It has been found by ſeveral late experiments, made by Dr. Alſton, that lime-water is an excellent remedy for the ſtone; and that it has alſo been given with extraordinary ſucceſs in acute fevers.

Sponius ſays, that when drank with milk or whey, it performs wonderful effects in internal ulcers, diarrhœas, and the dyſentery.

Lime-water on being mixed with linſeed oil, or the oil of olives, and well ſhaken, acquires the conſiſtence of a balſam, which is of ſingular ſervice when applied externally in freſh burns, and alſo conduces to ſtop inflammations. It may alſo be impregnated with copper, by ſtanding in a brazen baſon: by which means it aſſumes a beautiful ſaphire colour, and proves an excellent remedy againſt puſtules, ulcers, ſcabies, and itching of the eyes; and this laſt prepartion mixed with a little ſal ammoniac, is recommended againſt all humours, films, and other blemiſhes of the eyes, and is ſaid to be very efficacious when the eyes are hurt by the ſmall-pox; and there is no remedy more effectual for cancerous ulcers.

LIME-TREE, the Engliſh name of the tilia. See TILIA.

LIMITS *of Equations*, in algebra, a method of diſcovering the limits of the root of equations, by which their ſolutions is much facilitated.

Let any equation be propoſed, and having put p, q, r, s, t, v, &c. for the known quantities of the terms thereof, under their ſigns changed, viz. that of the ſecond p, that of the third q, of the fourth r, of the fifth s, and ſo on. And the ſigns of the terms being rightly obſerved, make $p=a$, $pa+2q=b$, $pb+qa+3r=c$, $pc+qb+ra+4s=d$, $pd+qc+rb+sa+5t=e$, $pe+qd+rc+sb+ta+6v=f$, and ſo on, obſerving the ſame law in the continuation of the ſeries; and a will be the ſum of the roots, b the ſum of the ſquares of each of the roots, c the ſum of the cubes, d the ſum of the biquadrates, e the ſum of the quadrato-cubes, f the ſum of the cubo-cubes, and ſo on. As in the equation $x^4-x^3-19xx+49x-30=0$, where the known quantity or co-efficient of the ſecond term is -1, of the third -19, of the fourth $+49$, of the fifth -30: you muſt make $1=p$, $19=q$, $-49=r$, $30=s$. And there will thence ariſe $a=(p=)\ 1$, $b=(pa+2q=1+38=)\ 39$, $c=(pb+qa+3r=39+19-147=)\ -89$, $d=(pc+qb+ra+4s=-89+741-49+120=)\ 723$: wherefore the ſum of the roots will be 1, the ſum of the ſquares of the roots 39, the ſum of the cubes -89, and the ſum of the biquadrates 723; hence the roots of that equation are 1, 2, 3, & -5, and the ſum of theſe $1+2+3-5=1$; the ſum of the ſquares, $1+4+9+25$, is 39; the ſum of the cubes, $1+8+27-125$, is -89; and the ſum of the biquadrates, $1+16+81+625$ is 723.

Now to collect the limits between which the roots of the equation ſhall conſiſt, if none is impoſſible, it will be neceſſary to obſerve, that when the ſquares of all the roots are affirmative, the ſum of the ſquares will be affirmative; and therefore greater than the ſquare of the greateſt root; and alſo that the ſum of the biquadrates of all the roots will be greater than the biquadrate of the greateſt root, and the ſum of the cubo-cubes greater than the cubo-cube of the greateſt root. Wherefore, to obtain that limit which no roots can paſs, find the ſum of the ſquare of the roots, and extract the ſquare root of that ſum, this root will be greater than the greateſt root of the equation; but to approach the greateſt root ſtill nearer, find the ſum of the biquadrates, and extract its biquadrate root; and for a third approximation, extract the cubo-cubical root of the ſum of the cubo-cubes of the roots.

Thus in the precedent equation, the ſquare-root of the ſum of the ſquares of the roots, or $\sqrt{39}$, is $6\frac{1}{2}$ nearly, and $6\frac{1}{2}$ is farther diſtant from 0 than any of the roots 1, 2, 3, -5. But the biquadrate root of the ſum of the biquadrates of the roots, viz. $\sqrt[4]{723}$, which is $5\frac{1}{4}$ nearly, comes nearer to the root that is moſt remote from nothing, viz. -5.

Another

Another method of finding the limits of an equation is this: Multiply every term of the propoſed equation by the number of its dimenſions, and divide the product by the root of the equation.

Then again, multiply every one of the terms that come out by a number leſs by unity than before, and divide the product by the root of the equation; proceed in this manner, by conſtantly multiplying by numbers leſs by unity than before, and dividing the product by the root, till at length all the terms are deſtroyed, whoſe ſigns are different from the ſign of the firſt or higheſt term, except the laſt: and that number will be greater than any affirmative root, which being writ in the terms that come out for the root, makes the aggregate of thoſe which were each time produced by multiplication, to have always the ſame ſign with the firſt or higheſt term of the equation.

Let the equation $x^5-2x^4-10x^3+30x^2+63x-120=0$, be propoſed; firſt multiply it thus; $x^{5}-2x^{4}-10x^{3}+30x^{2}+63x^{1}-120^{0}$. Then again, multiply the terms that come out, divided by x, thus; $5x^{4}-8x^{3}-30x^{2}+60x^{1}+63^{0}$, and dividing the terms that come out again by x, there comes out $20x^3-24x^2-60x+60$; which, to leſſen them, I divide by the greateſt common diviſor 4, and you have $5x^3-6x^2-15x+15$. Theſe being again multiplied by the progreſſion 3, 2, 1, 0, and divided by x, become $15xx-12x-15$, and again divided by 3, becomes $5xx-4x-5$: and theſe multiplied by the progreſſion 2, 1, 0, and divided by $2x$, gives $5x-2$. Now ſince the higheſt term of the equation x^5 is affirmative, I try what number writ in theſe products for x will cauſe them all to be affirmative. And by carrying 1, you have $5x-2=3$ affirmative; but $5xx-4x-5$, you have -4 negative: wherefore the limit will be greater than 1. I therefore try ſome greater number, as 2, and ſubſtituting 2 in each for x, they become

$5x-2=8$
$5x^2-4x=-5=7$
$5x^3-6x^2-15x+15=1$
$5x^4-8x^3-30x^2+60x+63=79$
$x^5-2x^4-10x^3+30x^2+63x-120=46$.

Wherefore, ſince the numbers that come out 8, 7. 1. 79. 46. are all affirmative, the number 2 will be greater than the greateſt of the affirmative roots. In like manner, if we would find the limit of the negative roots, we muſt try negative numbers, or, which is the ſame thing, change the ſigns of every other term, and try affirmative ones. But having changed the ſigns of every other term, the quantities in which the numbers are to be ſubſtituted, will become

$5x+2$
$5x^2+4x-5$
$5x^3+6xx-15x-15$
$5x^4+8x^3-30x^2-60x+63$
$x^5+2x^4-10x^3-30x^2+63x+120$.

From theſe, let ſome quantity be taken wherein the negative terms ſeem moſt prevalent; ſuppoſe $5x^4+8x^3-30x^2-60x+63$; and here ſubſtituting for x the numbers 1 and 2, there come out the negative numbers -14 and -33; whence the limit will be greater than -2. But ſubſtituting the number 3, there comes out the affirmative number 234. And in like manner in the other quantities, by ſubſtituting 3 for x, there comes out always an affirmative number, which may be ſeen by bare inſpection. Wherefore the number -3 is greater than all the negative roots. And ſo you have the limits 2 and -3, between which are all the roots.

Theſe limits are of uſe both in the reduction of equations by rational roots, and in the extraction of ſurd roots out of them; for it is certain, that if after trying all the diviſors of the laſt term of the equation, which here is 120, none of them writ in the equation for x would make all the terms vaniſh, the equation will admit of no root but what is ſurd. But there are many diviſors of that term, namely, $1,-1,2,-2,3,-3,4,-4,5,-5,6,-6,8,-8,10,-10,12,-12,15,-15,20,-20,24,-24,30,-30,40,-40,60,-60,120$, and -120. To try all theſe diviſors would be tedious. But it being known that the roots are between 2 and -3, it will be ſufficient to try thoſe only that are within theſe limits, viz. the diviſors 1, and -1, and -2. For if none of theſe are the root, it is certain that the equation admits of no root but what is ſurd.

LIMITS *of a Planet*, its excurſion from the ecliptic, or; which is the ſame thing, the points of its greateſt latitude.

LIMITATION, in law, ſignifies a certain ſpace of time allowed for bringing actions in.

LIMITATION *of Eſtate* is the length of time an eſtate is to continue in the poſſeſſion of a perſon or family.

LIMITED PROBLEM, a problem that admits but of one ſolution, as to make a circle paſs through three given points, not lying in the ſame right line.

LIMNING, the art of painting in water-colours, in contradiſtinction to painting, which is done in oil colours. See PAINTING.

LIMON, the lemon-tree. See LEMON.

LIMPET, the Engliſh name of a ſhell-fiſh, called by authors patella. See PATELLA.

LINE, *Linea*, in geometry, a quantity extended in length only, without any breadth or thickneſs. It is formed by the flux or motion of a point. See the article FLUXION.

There are two kinds of lines, viz. right lines and curve lines. If the point A, (plate LXXXI. *fig.* 1.) move towards B; by its motion, it deſcribes a line, and this, if the point go the neareſt way towards B, will be a right or ſtraight line, whoſe diſtinction therefore is the neareſt or ſhorteſt diſtance between any two points; or a line, all whoſe points tend the ſame way. If the point go any way about, as in one of the lines A B C, or A c B, it will trace out either a crooked line as the upper A c B, or elſe two more ſtraight ones as in the lower A C B. Right lines are all of the ſame ſpecies, but curves are of an infinite number of different ſpecies. We may conceive as many as there may be different ratios between their ordinates and abſciſſes. See the articles ABSCISS and ORDINATE.

Curve lines are uſually divided into geometrical and mechanical; the former are thoſe which may be found exactly in all their points; the latter are thoſe, ſome or all of whoſe points are not to be found preciſely, but only tentatively, or nearly.

Curve lines are alſo divided into the firſt order, ſecond order, third order, &c. See the article CURVE.

Lines conſidered as to their poſitions, are either parallel, perpendicular, or oblique, the conſtruction and properties whereof ſee under PARALLEL, &c.

Euclid's ſecond book treats moſtly of lines, and of the effects of their being divided and again multiplied into one another.

LINE, in geography, the ſame with equator. See the article EQUATOR.

LINES, in aſtronomy, are, 1. Fiducial line, the line or ruler which paſſes through the middle of an aſtrolabe, or the like inſtrument, and on which the ſights are fitted, otherwiſe called alhidade, index, dioptra, and mediclinium. See the article ASTROLABE. 2. The horizontal line. 3. Iſochronal line. 4. Meridian line. 5. Line of the nodes. See the articles HORIZONTAL, ISOCHRONAL, MERIDIAN and NODES.

LINES, in perſpective, are, 1. Geometrical line, which is a right line drawn in any manner on the geometrical plane. 2. Terreſtrial line, or fundamental line, is a right line wherein the geometrical plane, and that of the picture or draught interſect one another, ſuch is the line N I, (plate LXXXI *fig.* 2.) formed by the interſection of the geometrical plane L M, and the perſpective plane H K. 3. Line of the front, is any right line parallel to the terreſtrial line. 4. Vertical line, the common ſection of the vertical and of the draught. 5. Viſual line, the line or ray imagined to paſs from the object to the eye. 6. Line of ſtation, according to ſome writers, is the common ſection of the vertical and geometrical planes. Others, as Lamy, mean by it the perpendicular height of the eye above the geometrical plane. Others a line on that plane, and perpendicular to the line expreſſing the height of the eye. 7. Objective line, the line of an object from whence the appearance is ſought for in the draught or picture.

LINES, in dialling, are, 1. Horizontal line, the common ſection of the horizon and the dial-plane. See DIAL. 2. Horary lines, or hour-lines, the common interſections of the hour-circles of the ſphere, with the plane of the dial. 3. Subſtylar line, that line on which the ſtyle or cock of a dial is duly erected, and the repreſentation of ſuch an hour-circle as is perpendicular to the plane of that dial. 4. Equinoctial line, the common interſection of the equinoctial and plane of the dial.

Contingent LINE. See CONTINGENT.

LINE *of Meaſures* is uſed by Oughtred, to denote the diameter of the primitive circle in the projection of the ſphere in plano, or that line in which the diameter of any circle to be projected falls. In the ſtereographic projection of the ſphere in plano, the line of meaſures is that line in which the plane of a great circle perpendicular to the plane of the projection, and that oblique circle which is to be projected, interſects the plane of the projection; or it is the common ſection of a plane paſſing through the eye-point and the center of the primitive at right angles to any oblique circle which is to be projected, and in which the center and pole of ſuch circle will be found.

LINE *of Direction of the Earth's Axis*, in the Pythagorean ſyſtem of aſtronomy, the line connecting the two poles of the ecliptic and of the equator when they are projected on the plane of the former.

LINE *of Direction*, in mechanics, that wherein a body actually moves, or would move, if it were not hindered. It alſo denotes the line that paſſes through the center of gravity of the heavy body to the center of the earth, which muſt alſo paſs through the fulcrum, or ſupport of the heavy body, without which it would fall.

LINE *of Gravitation*, of any heavy body, a line drawn through its center of gravity, and according to which it tends downwards.

LINE *of the ſwifteſt Deſcent*, of a heavy body, is the cycloid. See CYCLOID.

LINE *of a Projectile*. See PROJECTILE.

LINES *on the Plain Scale*, are the line of chords, line of ſines, line of tangents, line of ſecants, line of ſemitangents, line of leagues, the conſtruction and application of which ſee under the words SCALE, SAILING, &c.

LINES *on Gunter's Scale* are the line of numbers, line of artificial ſines, line of artificial tangents, line of artificial verſed ſines of rhumbs, line of artificial tangents of the meridian line, and line of equal parts; for the conſtruction and application of which, ſee GUNTER'S SCALE.

LINES *of the Sector* are the line of equal parts, or line of lines, line of tangents, line of ſecants, line of polygons, line of numbers, line of hours, line of latitudes, line of meridians, line of metals, line of ſolids, line of planes; for the conſtruction and uſe of which, ſee the article SECTOR.

LINES, in fortification, are thoſe of approach, capital, defence, circumvallation, contravallation, of the baſe, &c. See the articles APPROACH, CAPITAL, &c.

To LINE *a Work*, ſignifies to ſtrengthen a rampart with a firm wall; or to encompaſs a parapet or moat with good turf, &c.

LINE, in the art of war, is underſtood of the diſpoſition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked. See ARMY.

LINE *of Battle*, in the marine, the array in which a fleet or ſquadron of ſhips of war is formed to engage with an enemy.

In this manoeuvre the ſhips are drawn up about one hundred fathoms diſtant, a-head of each other, the admiral being in the center, whoſe chief judgment is to form it in a proper diſpoſition and ſtrength throughout, from the van to the rear; in doing which, particular care muſt be had to make the center ſtrong; for if that is forced or broke through, the battle is looked upon as loſt. Here it is to be obſerved, that in a ſea-action the center is made the ſtrongeſt; whereas in a land-fight it is the weakeſt; and the wings of an army are the ſtrongeſt, leſt the enemy, by forcing a wing, ſhould have the advantage of flanking, and conſequently putting the line in confuſion; for the ſame reaſon alſo, the van and rear of a fleet is not put into diſorder, becauſe care is taken to make them proportionally ſtrong to reſiſt the enemy; therefore the weakeſt part of the line will be in the quarters, as ſupported each way from the center throughout.

The line being thus formed, there ought to be a corps-de-reſerve, as many as may be thought neceſſary, if they can be diſpenſed with. But firſt, the line muſt ſtretch out the length of the enemy's, if poſſible, or elſe they will have the advantage, and by tacking and doubling upon your line, put the van and rear into confuſion.

It is a maxim in naval diſcipline that a commanding flag-ſhip ſhould never go out of her way for any ſhip whatever, unleſs that ſhip ſhould be diſabled, or that a ſudden ſhift of wind takes her unexpectedly. The reaſon is ſelf-evident: if the admiral gives way for one, or backs and fills for another's fancy or miſconduct, there would be no end to ſuch negligence or over-ſight; therefore the commanding flag-ſhip expects that every ſhip in his fleet will obſerve and take her motions from him and his ſeconds, whoſe diſtance from the admiral ſhould be a ſtandard for every other ſhip to follow in that from each other, as near as poſſible, except when her ſignal is made to back or fill, or make more or leſs ſail.

The ſeconds to the commanding flag-ſhip are particularly to regard her, to move as ſhe does, whether the other ſhips do or not, or cannot do; for they are called ſeconds to guard and attend the admiral's ſhip.

It is the duty of every officer, as ſoon as the ſignal is diſplayed for the line, to crowd, if poſſible, into his ſtation, and not lie, through indolence or negligence, braced to or a-back, but make ſail to windward, or bear away to leeward, in order to form the line immediately, and then each leading ſhip to mind her tack as the wind is, to lead and give room.

The commanding flag-officer, when his ſhips are arranged into a line, obſerves the ſtrength of the enemy's line throughout, and acts accordingly, making more or leſs ſail, or what motion he might think moſt to his advantage. He is not to take his motion from his leading ſhip, but upon ſome particular occaſion, ſignal, notice, or meſſage ſent to him.

In a line of battle the weathermoſt fleet, or that which has the weather-gage, in the ſea language, is generally allowed to have the advantage, although there are ſeveral arguments on the other hand in favour of the lee-ſide. We ſhall endeavour to ſtate the mutual advantages.

1. The weather-gage is ſooneſt clear of ſmoke; and of courſe that line can better obſerve the ſignals which are ſpread than the ſhips to leeward can, which muſt have the continuance of both its own and of the enemy longer.

2. If the weather-ſhips are more in number than the enemy's fleet, they can detach ſome from their ſquadron, which, bearing down upon the rear of the enemy, muſt infallibly throw them into diſorder.

3. The fire-ſhips of the weather-line can, when they are ordered, more eaſily bear down upon the enemy, than thoſe of the lee can ply to windward, which can never be done againſt a line in action; but the weather fire-ſhips can bear down againſt all the reſiſtance that can be made by the enemy.

Advantages of the lee-line. — 1. If one, two, or more of the ſhips to windward ſhould be diſabled, they muſt inevitably drive to leeward, and become a prey to the enemy.

2. The ſhips of the lee line can more readily bear away before the wind, and have their places ſupplied by ſhips from the corps de-reſerve, in caſe of being diſabled or meeting with any diſaſter.

3. The line to leeward can keep their ports longer open in a ſtrong wind with a high ſea, when thoſe to windward, in all probability, may be obliged to ſhut the ports of their lower tier of guns, to prevent the water from ruſhing in between decks, which may be attended with the moſt fatal conſequences.

4. The lee-line can more eaſily obſerve the men on the decks of the ſhips to windward, as they heel, and when the ſmoke does not intercept their ſight: at which time the marines and top-men may eaſily take aim at, and deſtroy them with muſkets or carabines.

LINE A-BREAST, an arrangement in which the whole ſquadron advances uniformly with all the ſhips parallel to

each other; ſo that the length of each ſhip forms a right line with the line a-breaſt. See DIVISION, SQUADRON, and NAVAL *Engagement*.

LINE, in fencing, that part of the body oppoſite to the enemy, wherein the ſhoulders, the right arm, and the ſword, ought always to be found; and wherein are alſo to be placed the two feet at the diſtance of eighteen inches from each other. In which ſenſe a man is ſaid to be in his line, or to got out of his line, &c.

LINE *of Demarcation*, or *Alexandrian* LINE, a meridian paſſing over the mouth of the river Moragnon, and by the capes Houmas and Mallabrigo, ſo called from pope Alexander VI. who, to end the diſpute between the crowns of Caſtile and Portugal, about their boundaries, drew an imaginary line on the globe, which was to terminate the pretenſions of each. By this partition, the Eaſt Indies fell to the ſhare of the Portugueſe, and the Weſt Indies to the Caſtilians.

LINE *of the Synodical*, in reference to ſome theories of the moon; is a right line ſuppoſed to be drawn through the centers of the earth and ſun: and, if it be produced, quite through the orbits: it is called the line of the true ſyzygies: but a right line imagined to paſs through the earth's center, and the mean place of the ſun, is called the line of the mean ſyzygies.

LINE, in genealogy, a ſeries or ſucceſſion of relations in various degrees, all deſcending from the ſame common father.

Direct line, is that which goes from father to ſon; being the order of aſcendants and deſcendants.

Collateral line is the order of thoſe who deſcend from ſome common father, related to the former, but out of the line of aſcendants and deſcendants: in this are placed uncles, aunts, couſins, nephews, &c. See DIRECT and COLLATERAL.

LINE alſo denotes a French meaſure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot.

LINES, in muſic, the name of thoſe ſtrokes drawn horizontally on a piece of paper, on and between which the characters and notes of muſic are diſpoſed: their number is commonly five; when another is added, for one, two, or more notes, it is called a ledger-line.

LINES, in heraldry, the figures uſed in armories, to divide the ſhield into different parts, and to compoſe different figures. Theſe lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the ſtraight or plain lines.

LINEA *Alba*, in anatomy, a white line which runs from the cartilago enſiformis to the os pubis, dividing the abdomen exactly in the middle; and is formed out of the tendons of the oblique and tranſverſe muſcles.

It receives a twig of a nerve from the intercoſtals in each of its digeſtations or indentings.

LINEAMENT, among painters, implies the out-lines of a face.

LINEAR PROBLEM, in mathematics, ſuch a problem as may be ſolved geometrically, by the interſection of two right lines: as meaſuring an inacceſſible height by means of two unequal ſticks, &c. It is alſo called a ſimple problem, and is capable but of one ſolution.

LINEN, in commerce, a well-known kind of cloth, chiefly made of flax. See FLAX.

LINIMENT, *Linimentum*, in pharmacy, a compoſition ſomewhat thinner than an unguent, and thicker than an oil, uſed for anointing the body in various intentions.

LINNET, *Linaria*, in ornithology, a bird of the ſize of the goldfinch; the head is ſmall and flatted; the eyes are ſmall, and hazel; the beak is conic, very ſmall, and ſharp at the point; the head, neck, and back are variegated with a bright brown and white; the breaſt and belly are pale, but in the male, eſpecially in the ſummer, there is a redneſs on the top of the head and all over the breaſt. This is a ſinging bird, and ſometimes has young ones four times a year, eſpecially if they are taken from the dam before they are able to fly, which may be done four days after they are hatched.

LINSEED, the ſeed of the plant linum. See the article LINUM.

Linſeed bruiſed and ſteeped in water, gives it very ſoon a thick mucilaginous nature, and communicates much of its emollient virtues to it. It is anodyne, attemperating, and of great ſervice in ſuppreſſions of urine from inflammation and heat; it envelops the acid ſalts of the urine, and prevents their vellicating and wounding the tender parts; and in ſome meaſure ſupplies the mucus of the bladder, when abraded and worn off. It is to be given in decoction, or infuſion, on theſe occaſions: the infuſion is not to be made too thick or mucilaginous, becauſe in that caſe it loads the ſtomach, and breeds flatulences in the inteſtines. A ſlight infuſion of linſeed, by way of tea, is recommended by many as an excellent pectoral; and the ſeed is a common and very good ingredient in clyſters. Externally, this ſeed, ground to powder, is an excellent emollient; as is alſo the ſtrong mucilage, made by boiling the ſeeds a long time: the oil drawn from it by expreſſion is of great ſervice in coughs, pleuriſies, and many other caſes.

LINSPINS, in the military art, ſmall pins of iron, which keep the wheel of a cannon, or waggon, on the axle-tree; for when the end of the axle-tree is put thro' the nave, the linſpin is put in, to keep the wheel from falling off.

LINSTOCK, in the military art, a wooden ſtaff, about three feet long, upon one end of which is a piece of iron, which divides in two, turning from one another, having each a place to receive the match, and a ſcrew to keep it faſt: the other end is pointed, and ſhod with iron, to ſtick in the ground. It is uſed, by gunners, to fire the guns.

LINT, *Linum*, the flax of which linen is made. See FLAX and LINEN.

In ſurgery, the term lint denotes the ſcrapings of linen which is uſed in dreſſing wounds, and is made up in various forms, as tents, doſſils, pledgets, &c. See the articles TENT, DOSSIL, &c.

LINTEL, in architecture, a piece of timber that lies horizontally over door-poſts and window-jambs, as well to bear the thickneſs of the wall over it, as to bind the ſides of the wall together.

LINUM, flax, in botany, a genus of plants, the flower of which is infundibuliform, conſiſting of five oblong petals; its fruit is a globoſe capſule, divided into ten cells, in each of which is a ſingle acuminated ſeed. See FLAX and LINSEED.

LION, *Leo*, in zoology, the ſtrongeſt and fierceſt of all quadrupeds.

The head of the lion appears very large in proportion to its body, and is the moſt fleſhy of the heads of all the known animals. Its jaw-bones alſo are remarkably large. The breaſt alſo appears very large, but this is only owing to the great quantity of long hair that covers it, for the ſternum is ſmaller than that of moſt animals of the ſame ſize. The tail, which is very long, appears alſo of the ſame thickneſs all the way, but this is wholly owing to the growth of the hair. The tail itſelf is largeſt at the baſe, and thence goes taper to the point; but the hair, being very ſhort near its baſe, and continuing to grow longer all the way, as that decreaſes in thickneſs, is ſo exactly proportioned in this growth, that it always gives the whole tail this regular appearance.

The long hair that grows about the neck and breaſt, and makes what is called the mane of the lion, only differs from the hair of the reſt of the body in length, having no greater thickneſs, or rigidity, like that of the manes of other animals. The claws of the lion have no caſes, as Pliny pretends that they have, for the animal to withdraw them into in walking; but Plutarch, Solinus, and ſome others, are much more in the right, in ſaying that the lion draws them up backwards when he walks, and places them cloſely among the articulations of the toes.

It is certain that the laſt joint but one of every toe in this creature has a peculiarly eaſy joint for motion, and by means of this the laſt joint, with the claw that is affixed to it, are very readily drawn up, and hid upon the foot, and placed wholly out of the way of being hurt in walking. This creature, therefore, does not put the extremities of its toes to the ground in walking, but the termination of each toe, as to its touching the earth, is the joint of the laſt piece with the laſt but one. This drawing up of the laſt joint of every toe, by means of which

which each claw is hid between the toe it belongs to and the next, is the effect of a ligament, which in its natural ſtate is ſo ſhortened, as to keep them in this poſition: and it is only by the action of a very ſtrong muſcle, that this joint can be pulled downward, when the claws are to be uſed, the ligament beforementioned always drawing them naturally into their firſt poſition again, as ſoon as the force of the muſcle is over.

The lion has fourteen teeth in each jaw, four inciſores, four canine, and ſix molares. The inciſores are ſmall; the canine are unequal in ſize, two being very large, and two very ſmall; the large ones are an inch and half long, and are the only ones the ancients allowed to be canine teeth. The molares alſo are irregular in ſize, the anterior ones being very ſmall, the others large, and terminated by three or four points, forming a ſort of flower-de-luce.

Ariſtotle, Ælian, and others ſay, that the neck of the lion is all compoſed of one unjointed bone. It appears indeed very rigid in this creature, but it does not proceed from ſo ſtrange a cauſe, but is found owing to this, that the ſpinoſe apophyſes of the vertebræ of the neck are long, and faſtened together by extremely ſtrong and rigid ligaments.

The tongue of the lion is very rough and rigid, being covered with a great number of prominences of a hard matter, reſembling that of a cat's claws, and nearly of the ſame ſize, the baſe of each being a round fleſhy prominence on the ſurface of the tongue.

The eyes of the lion are clear and bright, even after the creature is dead. The common obſervation that this creature ſleeps with its eyes open, is founded on this, that it has a very thick membrane lodged in the greater canthus of the eyes, which it can extend over the whole eye upon occaſion, as birds do their membrana nictitans, and thus will have no occaſion to ſhut its eye-lids, in order to exclude the light. It is very remarkable that the common cat has all the ſingular ſtructure of the ſeveral parts as the lion has, its claws, feet, tongue and eyes, being of the ſame kind, and its internal parts bearing as ſtrong a reſemblance.

The heart of the lion is greatly larger than that of any other creature of the ſame ſize, being ſix inches long, and four in diameter, in the largeſt part, and terminating in a very ſharp point. The brain is as remarkably ſmall; and upon the compariſon of this with the great quantity of brain in a calf, and purſuing the obſervation through ſeveral other creatures, as to the proportion of brain they have, it does not appear that a ſmall quantity of brain is a mark of folly, but uſually of great ſubtlety, and of a cruel diſpoſition. *Mem. pour l'Hiſtoire des Anim.*

LIONCELLES, in heraldry, a term uſed for ſeveral lions borne in the ſame coat of arms.

LIP, *Labium*, or *Labrum*, in anatomy, the exterior fleſhy covering of the mouth. See MOUTH.

The cheeks and lips form the ſides and entry of the cavity of the mouth. They are formed in general by the connection of ſeveral fleſhy portions, of different breadths, fixed round the two jaws, covered on the outſide with the ſkin and fat, and lined on the inſide by a glandulous membrane. Beſides this, the lips have a ſoft ſpongy ſubſtance, which ſwells and ſubſides on certain occaſions, independently of the action of the muſcles; and is mixed with fat.

The ſubſtance that forms the red border of the lips is a collection of very fine, long, villous papillæ, cloſely connected together, and covered by a fine membrane; which ſeems to be both a continuation of the epidermis, and of that pellicle which covers the glandulous membrane of the cavity of the mouth. This ſubſtance is extremely ſenſible. The internal membrane of the upper-lip forms a ſmall middle frænum above the firſt dentes inciſorii.

The arteries which go to the lips are ramifications of the external carotid, and principally of the external and internal maxillary branches. See ARTERY.

The veins are ramifications of the external anterior jugular. See VEIN.

The nerves of theſe parts come from the maxillaris ſuperior and inferior, which are branches of the fifth pair; and alſo from the portio dura of the auditory nerve, or ſympatheticus minimus, the ramifications of which are ſpread in great numbers on all theſe parts, and communicate very ſingularly with the nerves of the fifth pair in ſeveral places.

There is ſo much variety in the muſcles of the lips, in different objects, that it is not at all ſurpriſing to find anatomiſts diſagree in the deſcription of them.

The muſcles of the lips are uſually divided into common and proper; the common are thoſe which end at the angles of the two lips; and thoſe are proper which are fixed in one lip only, which are again ſubdivided into proper muſcles of the upper-lip, and proper muſcles of the under-lip.

The common muſcles are the ſemi-orbiculares, ſupra-ſemi-orbiculares, buccinatores, and zygomatici majores.

The proper muſcles of the upper-lip are the zygomatici minores, canini, inciſorii laterales, and inciſorii medii.

Thoſe of the under-lip, the triangulares, triangularium collaterales, quadratus, inciſorii inferiores, and cutanei.

The upper-lip is ſometimes moved by the action of the muſcles of the noſe, eſpecially the pyramidales; and both lips, either jointly or ſeparately, are moved by ſuction, without the aſſiſtance of their proper muſcles.

The common muſcles of the lips either draw both corners of the mouth at once, or only one at a time, according to the different direction of their fibres. The proper muſcles pull the different parts of the lips in which they are inſerted.

The buccinators, in particular, may ſerve to move the food in maſtication.

Hare-LIPS, in ſurgery, a diſorder in ſome perſons wherein the upper-lip is ſo divided, as to reſemble a hare's lip. This diviſion is ſometimes ſmall, at other times it is double, like the letter M, and then termed the double hare-lip. Beſides the deformity cauſed by this diſorder, it hinders infants from ſucking, and adults from ſpeaking diſtinctly. Sometimes this accident happens to the lower lip from the ill treatment of a wound, and this is called the ſpurious hare-lip; the true kind is born with the infant. The leſs and more equal the fiſſure of the hare-lip is, it is generally ſo much the more eaſily cured. In ſome infants, the diviſion of the lip is ſo large and irregular, that there can be but little hopes of a cure, which may, however, be eaſily performed on the very ſame lip, when adult. Sometimes too we meet with a tooth projecting forward into the fiſſure; in this caſe it cannot be cured without firſt taking out the tooth. In a recent hare-lip, or one made by a wound, the cure is to be performed by the knotted ſuture. See the articles SUTURE and WOUND.

In curing the hare lip, where part of the lip is wanting, no attempt can be made to ſupply what is deficient, but only to unite thoſe parts which are divided, by taking off the ſkin from the edges of the fiſſure, and then cauſing them to unite and grow together, by paſſing through them two or three needles, made of gold or ſilver, pointed with ſteel, from the right to the left, beginning with the upper-part of the fiſſure, and inſerting them at about a ſtraw's breadth from each other: the ſurgeon having thus entered the needles, and cleanſed the bleeding lips with a ſpunge, he takes a piece of ſtrong waxed thread or ſilk, and faſtening it about one end of the needle, he winds it over the other end, and back again. Having done this, he afterwards ſecures it by a knot; by this means the edges of the lips are brought cloſe together, and the upper-part or ſurface kept ſmooth and even. To heal the wound internally, it is dreſſed with ſoft lint dipped in honey of roſes, and put between the gums and lip; but this practice can only be followed with adults: the external part of the wound is at the ſame time dreſſed with balſam of Peru, or ſome other vulnerary unguent, covered with lint and compreſs, and over that a ſticking plaſter with four heads, two of which are faſtened on the left ſide of the lip, and two upon the right, and the whole ſecured by a ſling or fillet, whoſe extremities may be faſtened about the head, either by a knot or pins. But it muſt here be obſerved, that when the fiſſure appears large and deep, ſo that the two parts of the lip cannot be eaſily joined, it will be neceſſary, before the above operation, to divide the frænulum of the upper-lip from the gum, with a pair

of

of ſciſſars, but without wounding the gum, or uncovering the jaw. Though the hæmorrhage is often very plentiful in performing theſe operations on young infants, yet it is not dangerous, ſince it prevents an inflammation, and generally ceaſes after tying the bandages.

The dreſſings ought not to be moved before the third day, unleſs ſome accident makes it neceſſary; and then it muſt be done with great caution, to avoid ſeparating the parts in contact. If the lips of the wound appear conjoined, three or four days after the operation, you may then venture to draw out the middle needle, when there are three, or the upper one, when there are only two; and two or three days after draw out the other: the cure muſt be completed by dreſſing every day, as at firſt.

LIPOTHYMIA, in medicine, the name of a diſeaſe uſually confounded with the ſyncope, but really different from it in many particulars.

The lipothymia is a very conſiderable abolition of the vital and animal faculties, at leaſt to appearance: and the ſyncope is a plenary or total abolition of them, as far as appears to us at the time. It is eaſy to ſee, however, that theſe are only two different ſtages of the ſame diſtemperature. The lipothymy is ſometimes an idiopathic, ſometimes a ſymptomatic diſeaſe, and moſt frequently attends the ſcurvy, malignant fevers, and other diſorders; the ſyncope is idiopathic, and attacks perſons in health as well as thoſe that are diſeaſed. The lipothymy is always eaſily diſtinguiſhed from a convulſed ſtate of the body, by this, that the limbs are all flaccid in it. The ſyncope differs from death only in degree; and the body being flaccid in this, and growing rigid under the laſt convulſions in death, is the only diſtinction of them in extreme caſes.

LIQUOR MINERALIS ANODYNUS, is a name given by Hoffman to a liquor of his invention, famous at this time in Germany, and ſuppoſed by Burggrave to be made in this manner: take oil of vitriol, and Indian nitre, of each four ounces; diſtil the ſpirit gradually from this, by a retort: pour two ounces of the ſpirit cautiouſly and ſucceſſively, into fifteen ounces of ſpirit of wine, highly rectified; diſtil this, and there comes over a very fragrant ſpirit: this is to be again diſtilled, to render it perfectly pure, adding firſt to it a ſmall quantity of oil of cloves, and a quantity of water, equal to that of the ſpirit; after this, as ſoon as the watery vapours begin to riſe, the whole proceſs is to be ſtopped, and the ſpirit kept alone in a bottle, well corked. This has great virtues as an anodyne, diaphoretic, antiſeptic, and carminative. It is not certain that this is the ſame with Hoffman's, that author never having publiſhed his manner of making it; but it appears the ſame to the ſmell and taſte, and has the ſame virtues.

LIQUORICE, *liquoritia glycyrrhiza*, and *radix dulcis*, a ſweet root of conſiderable uſe in medicine.

This plant, deſcribed by all the botanical authors under the name of glycyrrhiza vulgaris, grows to four or five feet high, its ſtalks are hard and woody, its leaves are ſmall and roundiſh; and they ſtand many together on the two ſides of a rib, making what authors call a winged leaf. They are viſcous to the touch; the flowers are of the papilionaceous kind, ſmall, and bluiſh.

The plant is of the diadelphia decandria of Linnæus, and of the herbæ flore papilionaceo ſeu leguminoſæ of Mr. Ray. Liquorice grows wild in many parts of France, Italy, Spain, and Germany. It is cultivated in great abundance in Yorkſhire, and in many other parts of England; and by the good order we keep the ſoil in, produce better roots, longer, evener, and more ſucculent than are to be had from any other part of the world. The reſt of Europe is in great meaſure furniſhed by what grows about Bayonne and Saragoſſa in Spain.

The ground deſigned for liquorice muſt be well dug, and dunged the year before, that the dung may be thoroughly rotted in it; and juſt before it is planted, the earth is to be dug three ſpades deep, and laid very light. The plants to be ſet ſhould be taken from the ſides or heads of the old roots, and each muſt have a very good bud, or eye, or otherwiſe they are ſubject to miſcarry; they ſhould alſo be about ten inches long, and perfectly ſound. The beſt ſeaſon for planting them is the end of February, or the beginning of March, and this muſt be done in the following manner: the rows muſt be marked by a line drawn a-croſs the bed, at two feet diſtance; and the plants muſt be ſet in theſe by making a hole of their full depth, and ſomething more, that the eye of the root may be an inch below the ſurface: they muſt alſo be ſet two feet diſtance from each other in the rows. When this is done, the ground may be ſowed over with onions, which, not rooting deep, will do the liquorice roots no injury for the firſt year. In October, when the ſtalks of the liquorice are dead, a little very rotten dung ſhould be ſpread over the ſurface of the ground. Three years after the time of planting, the liquorice will be fit to take up for uſe; and this ſhould be done juſt when the ſtalks are dead off; for, if taken up ſooner, the roots are very apt to ſhrink greatly in their weight. The roots about London look browner than thoſe which have been propagated in a leſs rich ſoil, but then they are much larger, and grow quicker to their ſize. *Miller's Gard. Dict.*

Liquorice is an excellent medicine in coughs, and all diſorders of the breaſt and lungs. It obtunds the ſharpneſs of acrid and ſalt humours. It is alſo recommended againſt diſorders of the kidneys and bladder, and is ſaid to take off the ſenſe of pain in many terrible complaints. It is an ingredient in almoſt all decoctions and ptiſans, in which it is eſteemed for obtunding acrimony, and for giving the whole a very pleaſant taſte, and drowning the worſt flavour of the other ingredients.

LIQUORICE *Juice*, the inſpiſſated juice of the common liquorice root, and is brought to us in rolls or cakes, covered uſually with bay leaves from Spain and Holland, from the firſt of which places it obtained the name of Spaniſh juice. It is to be choſen firm, but not tough, hard, and when broken, of a fine ſhining ſurface; ſuch as perfectly melts in the mouth, and does not taſte of burning, nor leaves any harſh or gritty particles between the teeth.

The manner of preparing it in Spain is this: they take up the roots in the month of July; they clean them perfectly as ſoon as taken out of the earth, and then hang them up in the air till nearly dry; after this they cut them into thin ſlices, and boil them in water till the decoction is extremely ſtrong; they then preſs it hard out to obtain all the juice they can from the root. They ſet this decoction by to ſettle a little, and when it has depoſited its coarſeſt parts, they pour it off into veſſels, in which they evaporate it over a fire, ſtrong at firſt, but milder afterwards, till it becomes of the conſiſtence of a thick extract; they then let the fire go out, and when the extract is ſo cool that they can handle it, they take out large parcels of it at a time; and working them well in the hands, they roll them out into long cylindric maſſes, which they cut out into ſuch lengths as they pleaſe, and rolling them over a parcel of half dried bay leaves, they pick up enough of them for a covering, which are in that condition laid in the ſun till perfectly dried; there is great nicety required at the end of the evaporation, to get the extract to a proper conſiſtence, without letting it burn. It is this the Spaniards are famous for: a great deal of liquorice juice is made in other places, but it is in a great meaſure either under-boiled, and conſequently ſoft, or is burnt.

Liquorice juice has the ſame virtues with the root it is produced from. It is a very famous remedy among the common people for coughs and all diſorders of the breaſt and lungs. It is commonly taken alone, holding a ſmall piece of it in the mouth till it gradually melts there; but the more agreeable way of taking it is in form of lozenges, of which there are many kinds, which it is the baſis of; in theſe it is mixed with other pectoral ingredients, and has the advantage of melting more eaſily in the mouth than in its own form. It is alſo an ingredient in the theriaca and ſome other of the compoſitions of the ſhops.

LIST, in commerce, the border of cloth, or of a ſtuff; ſerving not only to ſhew their quality, but to preſerve them from being torn in the operations of fulling, dyeing, and the like. See CLOTH, &c.

Liſt is uſed on various occaſions; but chiefly by gardeners, for ſecuring their wall trees.

LIST, in architecture, a little ſquare moulding, other-wiſe

wiſe called a fillet, liſtel, &c. See FILLET and MOULDING.

LISTING, the ſame as heeling, or inclining to one ſide. See HEEL and CAREEN.

LITANY, a ſolemn form of ſupplication to God, in which the prieſt utters ſome things fit to be prayed for, and the people join in their interceſſion.

LITERATI, in general, denotes men of learning; but is more particularly uſed by the Chineſe, for ſuch perſons as are able to read and write their language, which is remarkably difficult.

LITHARGE, a metalline ſubſtance, formed of the ſpume of lead.

The word is Greek, λιθαργυρος, which is formed of λιθος, a ſtone, and αργυρος, ſilver, becauſe it is found in furnaces where ſilver is refined.

This preparation, or, as it may be more properly called, recrement of lead, is of two kinds, differing in colour, though in no other quality: the ancients, as well as moderns, obſerved this difference, and called the one litharge of gold, and the other litharge of ſilver. This recrement of lead is not prepared by a formal proceſs on purpoſe; it is collected from the furnaces where ſilver is ſeparated from lead, or from thoſe where gold and ſilver are purified by means of that metal; but in the furnaces uſed for either of theſe purpoſes, it is generally run into lead again to ſerve for the ſame or other uſes. The litharge ſold in the ſhops is produced in the copper works, where lead has been uſed to purify that metal, or to ſeparate ſilver from it. Of all the various metalline and mineral ſubſtances, which are ſeparated from gold or ſilver, by means of lead, there is none but copper which remains embodied in and intimately joined with that metal after ſcorification; the others being either not at all received into the body of it, or, if they are, being either deſtroyed before ſcorification; or finally, if they remain mixed with it longer, they ſplit and deſtroy the veſſels. The recrement produced from this combination of lead with copper, is our common litharge. It is of a yellower or redder colour, as the fire has been more or leſs ſtrong; and is always compoſed of a multitude of thin flakes, reſembling the ſpangles of talc, in thoſe foſſils called micæ or glimmors.

The greateſt quantities of litharge are brought from Sweden, Germany, and Denmark. Poland furniſhes ſome, as does alſo England, but the Dantzic kind is eſteemed the moſt valuable. The beſt litharge is that which is moſt calcined, and of the livelieſt colour. Litharge on the whole is properly lead vitrified, either alone or with a mixture of copper.

Litharge is ſoluble in oil and all other unctuous ſubſtances, and thus diſſolved, it makes the baſis of a great part of the ointments and plaſters of the ſhops. It is drying, abſtergent, and ſlightly aſtrictive; and hence it is of great uſe in cleanſing ulcers, and diſpoſing them to incarnate.

LITHOCOLLA, a cement uſed by lapidaries for faſtening precious ſtones together. See the article CEMENT.

LITHONTRIPTICS, medicines which either break, or are ſuppoſed to have the virtue of breaking ſtones in the urinary paſſages.

The word is derived from the Greek λιθος, a ſtone, and θρυπτω, to break.

LITHOPHYTA, in botany, a ſubdiviſion of plants, ſo called from their approaching to a ſtony hardneſs, comprehending the iſis, ſpongia, millepora, tubipora, &c.

LITHOSPERMUM, gromwell, in botany, a genus of plants, the corolla of which conſiſts of a ſingle petal of the length of the cup: the tube is cylindric, the limb ſemiquinquifid, obtuſe, and erect: there is no pericarpium, but the cup becomes patulous and long, containing four broad, oval, acuminated, and hard ſeeds.

The ſeeds of this plant, being the only parts uſed in medicine, are accounted diuretic. Emulſions are made of them, with dog's graſs water.

LITHOTOMY, in ſurgery, cutting for the ſtone. See the article STONE.

Mr. Sharp lays down the following method of ſearching for the ſtone. The patient being laid on an horizontal table with his thighs elevated, and a little extended, paſs the ſound, or catheter, with the concave part towards you, till it meets with ſome reſiſtance in the perinæum, a little above the anus; then turning it without much force, puſh it gently on into the bladder, and if it meets with an obſtruction at the neck, raiſe its extremity upwards, by inclining the handle of it towards you; and if it does not then ſlip in, withdraw it a quarter of an inch, and introducing your fore finger into the rectum, lift it up, and it will ſeldom fail to enter. Though, upon ſearching, the ſurgeon may be aſſured of a ſtone in the bladder, yet he is not without farther inquiry to operate immediately; ſince there are ſome obſtacles that forbid the operation, either abſolutely, or only for a certain time. Among theſe, that of the greateſt conſequence is the gravel or ſtone in the kidneys, which is known by the pain in the loins, vomiting, retraction of the teſticles, numbneſs of the thighs, and often by matter which the inflammation produces in the kidneys. Difference of age makes an extreme difference in danger, infants and young people almoſt always recovering; but ſtill the operation is adviſeable in thoſe advanced in years, though it is not attended with near the ſame ſucceſs. Before the operation is performed it is proper to prepare the patient with a gentle purge the preceding day, and a clyſter early in the morning, which will be of great ſervice in cooling the body and making the operation leſs dangerous, where the rectum is liable to be wounded when full.

The moſt convenient time for the operation of lithotomy is ſpring or autumn, though when the patient is in exquiſite torment, or his life in danger, the preſent opportunity ſhould be embraced. Lithotomy is of two kinds: that made into the bladder is termed cyſtotomy; but when the ſtone is in the kidneys, which very rarely happens, the operation is termed nephrotomy.

With reſpect to the ſeveral methods of performing lithotomy for the ſtone in the bladder, they, according to Heiſter, are four: the firſt, and moſt ancient, is the apparatus minor, called likewiſe the Celſian or Guidonian method: the ſecond the apparatus magnus, or Marianus's method; the latter being termed the new, and the former the old method: the third is the apparatus altus, or hypogaſtric ſection, wherein the inciſion is made at the lower part of the abdomen in the anterior ſide of the bladder, immediately above the os pubis; whereas in the reſt it is made in the perinæum, between the anus and the ſcrotum: the fourth, and moſt modern method, was invented towards the end of the laſt century, and is termed the lateral operation.

1. The firſt method is now entirely laid aſide, though Heiſter thinks it practicable on boys under fourteen: the wound of the bladder in this operation, ſays Sharp, is made in the ſame place as is now practiſed in the lateral method; but its being impracticable on ſome ſubjects, and uncertain in all others, has made it to be univerſally exploded.

2. In performing lithotomy by the apparatus major, Mr. Sharp's directions for the ſituation of the patient are thus. Having laid the patient on a ſquare horizontal table, three feet four inches high, with a pillow under his head, let his legs and thighs be bent, and his heels made to approach his buttocks by tying his hands to the ſoles of his feet with a couple of ſtrong ligatures; and to ſecure him more effectually from ſtruggling, paſs a double ligature under one of his hams, and carry the four ſtrings round his neck to the other ham: then paſſing the loop underneath, make a knot by threading one of the ſingle ends through the loop; and thus the thighs are to be widened from each other, and firmly ſupported by proper perſons.

The patient thus ſituated, Heiſter directs the operation as follows: the operator, dipping the beak of a ſizeable and grooved ſteel catheter in oil, conveys it through the urethra into the bladder, and being aſſured there is a ſtone, turns the crooked part of the catheter in the bladder and urethra towards the left ſide of the perinæum, but the handle and penis which contains it, towards the right inguen, then delivers it to the aſſiſtant, who holds up the ſcrotum in the other hand; for the crooked convex part of the catheter thus elevated in the perinæum, renders that part of the urethra which is to be divided, ſufficiently

ficiently perceptible both to the ſight and touch. He next lays hold of the integuments of the perinæum with the fingers of his left hand, holding in his right the inciſion-knife, wrapped in linnen, as he would do a pen for writing: with this he makes a longitudinal incision downwards, about the middle of the left ſide of the perinæum near the ſuture, through the fat; then he again feels for the catheter, and afterwards divides the urethra in a direct line downwards, ſo that the end of the knife may paſs into the groove of the catheter. After a proper inciſion, the ſurgeon parts with his knife, inſerting in the groove of the catheter, if an aſſiſtant holds it, the nail of his finger or thumb: then he takes a male conductor, dips it in warm oil, and having paſſed it through the groove of the catheter and neck of the bladder into the bladder itſelf, extracts the catheter.

The male conductor being thus paſſed, a female conductor is introduced upon it, in ſuch a manner as the latter receives the prominent back of the former in its groove, and conveys it ſafely into the bladder through its neck. After this the two conductors are gently ſeparated by their handles, and then a ſtraight forceps, dipt in oil and ſhut very cloſe, is carefully conveyed into the bladder between the conductors. The forceps, after it is introduced, and the conductors withdrawn, muſt be opened ſeveral times to dilate the wound, and then ſhut to ſearch for the ſtone: when the ſtone is found, they muſt be opened with both hands, in ſuch a manner that one jaw, if poſſible, may lay hold under the ſtone, and the other above it. When the ſtone is thus intercepted, the forceps, by a gentle motion from ſide to ſide, muſt be brought towards the rectum, and the ſtone extracted downwards, becauſe the parts dilate and yield more eaſily that way, while upwards they meet with a reſiſtence from the os pubis: but if it lies concealed in any part of the bladder, and cannot be laid hold of by the forceps, the operator muſt paſs the two firſt fingers of his left hand into the anus, elevate the ſtone, and force it into them. If it is ſituated in the upper part of the bladder, behind the oſſa pubis, the inferior part of the abdomen muſt be preſſed downwards by the hand, that it may commodiouſly be taken hold of, and drawn out by the ſtraight or a crooked forceps; and if it is lodged on either ſide, the crooked inſtrument is moſt convenient.

When the ſtone is too large to be extracted whole, it muſt be broken by a forceps with teeth, and the fragments to be drawn out one after another. Laſtly, if the ſtone is too large and too hard to be either extracted or broken, a prudent ſurgeon will deſiſt, and heal the wound, or leave a fiſtula for the diſcharge of the urine. The ſtone being thus extracted, and the bladder cleared, the wound is cleanſed with a ſponge, the ligatures untied, the patient put to bed, and the wound now dreſſed with doſſils of ſcraped lint: if the hæmorrhage be too profuſe, it may be ſtopped by pledgets of lint dipt in a proper ſtyptic, and the arteries compreſſed with the fingers till it ſtops.

Theſe muſt be covered with a linnen-bolſter, and a large ſquare compreſs without a plaſter, ſecuring the whole with the T bandage, or that with four heads; and if they are ineffectual, the artery muſt be tied up with a crooked needle and thread. See the article HÆMORRHAGE.

After dreſſing, the patient muſt be ſupplied with plenty of ptiſan, barley-water, or a ſtrengthening and compoſing emulſion; his diet ſhould be the ſame as for people in fevers, or after great wounds. See the articles FEVER and WOUND.

3. The apparatus altus, or high operation, is performed as follows. The patient being duly prepared, and laid in a proper ſituation, a hollow ſilver catheter, with a flexible leathern tube at the end of it, is to be introduced into the bladder: to the tube muſt be fitted a large ſyringe, for the injecting of ſuch warm water, barley-water, or milk, as the patient can bear. When this is done, the catheter is extracted: then while an aſſiſtant introduces his two fore-fingers into the anus to elevate the ſtone and bladder, the operator makes an inciſion in a right line through the ſkin, fat, and abdominal muſcles, immediately above the oſſa pubis. The external wound ſhould be three fingers-breadth long in children, and four in adults; then introducing the left index, the ſurgeon feels for the liquor that diſtends the bladder, and then makes an inciſion into the bladder immediately above the junCture of the oſſa pubis: after which he paſſes a ſmall knife into the body of the bladder, ſo as to make a ſmall wound with the point only; through this aperture he paſſes a crooked or ſtraight knife, armed with a button, whereby he enlarges the wound upwards the breadth of one or two fingers. He then introduces his left index to draw the upper part of the bladder towards the navel, and then enlarges the wound downwards. Immediately after, he introduces the fore-finger of the other hand, and examines the ſize and ſituation of the ſtone, and accordingly he enlarges the wound either upwards or downwards, in order to extract it. And when the ſtone is extracted, and nothing left, the wound is dreſſed, and the patient treated much in the ſame manner as in the former caſe.

4. The fourth method, which is called the lateral operation, was performed by Cheſelden thus: every thing being properly prepared, he introduces a catheter, and afterwards makes an inciſion of a proper length, beginning where they end in the apparatus major, and continuing it downwards between the accelerator urinæ, and erector penis, on the left ſide of the inteſtinum rectum; and directing his knife to the poſterior part of the catheter, through the inferior and lateral part of the bladder, behind the proſtate gland, and above the ſeminal veſicles, he then continues it forwards through the ſphincter of the bladder, and left ſide of the proſtate glands into the membranous part of the urethra even to its bulb, which preſerves the rectum better than the lateral method.

Among Cheſelden's emendations, Douglas enumerates theſe. 1. If he finds the patient's pulſe low after the operation, he applies bliſters to the arms, which effectually raiſe his ſpirits. 2. If the wound grows callous, he lays on a piece of bliſter plaſter to erode it, by which new fleſh pullulates, and the wound unites. 3. If the wound be putrid, he mixes a little verdigreaſe with ſome digeſtive ointment.

Women are leſs ſubject to the ſtone in the bladder than men, and their urinary paſſages are more ſhort and lax, ſo that in general the ſtone being but ſmall, diſcharges itſelf with the urine, and when it happens to increaſe in the bladder, we have inſtances of its coming away ſpontaneouſly. Douglas propoſes to extract a ſmall ſtone in a woman, by dilating the urethra with a tent of gentian-root, or prepared ſponge; but when the ſtone is large, he approves of the high operation, diſtending the bladder with warm water, and compreſſing the urethra by an aſſiſtant's finger in the vagina, and then making an inciſion into the bladder immediately above the os pubis. This, Heiſter ſays, is a very proper method, when the ſtone is very large, and the patient young and healthy; but Morand, when the ſtone is ſmall, prefers the apparatus major.

Upon the whole, lithotomy appears to be a dangerous and precarious operation, nor can one method alone be depended on; but the ſurgeon muſt be determined in the choice, by the particular circumſtances of the caſe.

Nephrotomy, the ſecond ſpecies of lithotomy, is by moſt writers on the ſubject thought impracticable, who therefore abſolutely reject it; though we have many inſtances of perſons, who have been cured of wounds of the back penetrating to the kidneys. Heiſter mentions one cure of this kind performed by himſelf. Wounds, therefore, of the kidneys, eſpecially thoſe inflicted on the back, without penetrating into the cavity of the abdomen, he ſays, are often curable. And though Hippocrates prohibits his pupils from practiſing lithotomy, yet treating of diſorders in the kidneys, in his work, *De Intern. Affect.* he directs to make an inciſion near the kidney when it is tumified and elevated, and after extracting the pus, to diſcharge the gravel by diuretics; for this opening may preſerve the patient, who muſt otherwiſe die: and again, he ſays, when the kidney, being ſuppurated, tumifies near the ſpine, a deep inciſion ſhould be made upon the tumor near the kidney, or into the kidney itſelf. Hence it is manifeſt, that a wound in theſe parts did not appear ſo formidable to him. Rouſet, Rioſanus, and others, think nephrotomy may be practiſed with

with ſucceſs, if the opening is made where the ſtone is perceptible, and neither the emulgent artery, vein, nor ureter, wounded, nor the cavity of the abdomen penetrated. But beyond all diſpute it muſt be reaſonable, when nature points out the place by a tumor or abſceſs in the loins, preceding from a ſtone in the kidneys.

LITURGY, λειτυργια, a name given to thoſe ſet forms of prayer which have been generally uſed in the Chriſtian church. Of theſe there are not a few aſcribed to the Apoſtles and fathers, but they are almoſt univerſally allowed to be ſpurious.

The liturgy of the church of England was compoſed in the year 1547, ſince which time it has undergone ſeveral alterations, the laſt of which was in the year 1661, and of this liturgy Dr. Comber gives the following character. "No church was ever bleſſed with ſo comprehenſive, ſo exact, and ſo inoffenſive a liturgy as ours; which is ſo judiciouſly contrived, that the whole may exerciſe at once their knowledge and devotion; and yet ſo plain, that the moſt ignorant may pray with underſtanding; ſo full, that nothing is omitted, which ought to be aſked in public; and ſo particular, that it compriſeth moſt things which we would aſk in private; and yet ſo ſhort, as not to tire any that have true devotion. Its doctrine is pure and primitive; its ceremonies ſo few and innocent, that moſt of the Chriſtian world agree in them: its method is exact and natural, its language ſignificant and perſpicuous, moſt of the words and phraſes being taken out of the holy Scripture, and the reſt are the expreſſions of the firſt and pureſt ages."—And in the opinion of the moſt impartial and excellent Grotius, (who was no member of, nor had any obligation to, this church) "the Engliſh liturgy comes ſo near the primitive pattern, that none of the reformed churches can compare with it." Again, he ſays, "In the prayers, a ſcholar can diſcern cloſe logic, pleaſing rhetoric, pure divinity, and the very marrow of the ancient doctrine and diſcipline; and yet all made ſo familiar, that the unlearned may ſafely ſay, Amen."

LITUUS, in Roman antiquity, a ſhort ſtraight rod, only bending a little at one end, uſed by the augurs. See AUGUR.

LIVER, *Hepar*, in anatomy, a large and pretty ſolid maſs of a dark red colour, a little inclined to yellow, ſituated immediately under the arch of the diaphragm, partly in the right hypochondrium, which it fills almoſt entirely, and partly in the epigaſtrium, between the appendix enſiformis and ſpina dorſi, and terminating commonly in the left hypochondrium, into which it ſometimes runs a conſiderable way. The figure of the liver is irregular, it being arched or convex on the upper part, unequally concave on the lower, and very thick on the right and back-ſides. Towards the left and anterior ſides, its thickneſs decreaſes very much, and terminates then by a kind of edge; and its breadth is more extended from right to left, than from before backwards. The liver may be divided into two extremities, one great, the other ſmall; two edges, one anterior, the other poſterior; two ſides, one ſuperior and convex, which is ſmooth and poliſhed, and proportioned to the arch of the diaphragm; and one inferior, concave and uneven, with ſeveral eminences and depreſſions. It may likewiſe be divided into two lateral parts called lobes; one of which is termed the great or right lobe, the other the ſmall or left lobe. Theſe two lobes are diſtinguiſhed above by a membranous ligament, and below very plainly by a conſiderable ſciſſure lying in the ſame direction with the ſuperior ligament. The eminences on the concave ſide of the liver belong to the great lobe. The principal eminence is a ſort of triangular or pyramidal apophyſis ſituated backward, near the great ſciſſure, which diſtinguiſhes the two lobes. This triangular eminence is termed lobulus Spigelii, or, ſimply, the ſmall lobe of the liver. One of its angles advances a conſiderable way toward the middle of the lower ſide of the great lobe, and is loſt there. This angle is called the root of the lobulus. Toward the fore-ſide there is another eminence leſs prominent but broader; and to this eminence and the former the ancients gave the name of portæ. The depreſſions on the concave or lower ſide of the liver, which deſerve our attention, are four in number. The firſt is the ſciſſure which ſeparates the two lobes, which run acroſs the concave ſide, from the eminences already mentioned, to the anterior edge, where it terminates by a notch of different depths, in different ſubjects. This is termed the great ſciſſure of the liver; and in ſome ſubjects, part of it is an entire tube. The ſecond depreſſion is ſituated tranſverſely between the two eminences of the great lobe, and filled by the ſinus of the vena portæ, ſo called by the ancients, becauſe it lies between the eminences of the ſame name. The third depreſſion is backward, between the great lobe and lobulus Spigelii; and the vena cava paſſes through it. The fourth is a kind of ſulcus, between the lobulus and ſmall lobe of the liver; which, in the fœtus, ſerves to receive a venous canal loſt in adults, in which it appears only as a kind of ligament. This ſulcus is in ſome meaſure a continuation of the great ſciſſure, and joins the vena cava by an acute angle. Beſides theſe four depreſſions, there is one on the fore-part of the great lobe, in which the gall-bladder is lodged, and it ſometimes runs as far as the edge, where it forms a ſmall notch. We may likewiſe reckon, among theſe depreſſions, a ſmall cavity in the poſterior and lateral part of the lower-ſide of the great lobe, by which it reſts on the right kidney; and likewiſe a ſuperficial cavity in the left lobe, where it runs over the ſtomach. Laſtly, on the poſterior edge of the liver, there is a great ſinus common to both lobes, which gives paſſage to the ſpina dorſi and œſophagus, near the place where the vena cava deſcends; and we ſometimes meet with ſciſſures on both ſides of the liver, which are not ordinary.

The convex ſide of the liver is commonly connected to the diaphragm by three ligaments, which are only continuations of the membranous lamina of the peritonæum. One lies near the edge of the extremity of each lobe, and one in the middle; and they are accordingly termed right, middle, and left ligaments. There is a cellular ſubſtance in the duplicature of each, in which the blood-veſſels and lymphatics run, and which ſends off a kind of lamina into the ſubſtance of the liver. The right ligament ſometimes connects the great lobe to the cartilages of the falſe ribs; and the left ligament or that of the ſmall lobe is often double, and advances toward the middle ligament. This middle ligament begins below the great ſciſſure of the liver, near the eminences called portæ; and from thence paſſes through the anterior notch, and over the convex ſide of the liver, as the union of the two lobes, and is fixed obliquely in the diaphragm. It is likewiſe fixed along the upper and inner part of the vagina of the right muſculus rectus of the abdomen, in ſuch an oblique manner, as to be nearer the linea alba below than above. Beſides theſe ligaments, the great lobe of the liver is likewiſe connected to the right ala of the tendinous portion of the diaphragm, not by a ligament, but by a broad and immediate adheſion, without the intervention of the membrane of the peritonæum, which is only folded quite round this adheſion, and to form this external membrane of all the reſt of the body of the liver. This broad adheſion is commonly, though improperly called ligamentum coronarium; but in the firſt place it is not a ligament, as has been already obſerved; and ſecondly, it is not circular, but oval and very oblong: it is not in the upper part of the convex ſide of the liver, but along the poſterior part of the great lobe; the broad extremity of the adheſion lying near the notch, and the pointed extremity towards the right hypochondrium. The middle ligament, called improperly ligamentum hepatis ſuſpenſorum, contains in its duplicature a thick white rope, like a round ligament, which was the umbilical vein in the fœtus. Thus the lower part repreſents a flag, the convex edge of which is ſharp, and the other rounded: all theſe ligaments ſerve to keep the liver in its proper ſituation, and to hinder it from inclining too much towards either ſide: but we muſt not imagine that any of them ſerve to ſuſpend it, becauſe it is ſufficiently ſupported by the ſtomach and inteſtines, eſpecially when they are filled. When the ſtomach is empty, or when we faſt longer than ordinary, it is a common expreſſion to ſay, the ſtomach pinches us. As the liver is not then ſuſtained by the ſtomach and inteſtines, it deſcends by its own weight, and, principally by means of the middle ligament, pulls the diaphragm along with it. It is in that place therefore, that we have this uneaſy ſenſation, and not at the ſuper-

rior orifice of the ſtomach, as is commonly believed. The right or great lobe of the liver, which lies in the right hypochondrium, reſts on the right kidney, by a ſmall ſuperficial depreſſion above mentioned; and it likewiſe covers a portion of the colon, and the pylorus. About $\frac{2}{3}$ of the ſmall or left lobe lie in the middle of the epigaſtrium, and the remaining third part advances over the ſtomach, towards the left hypochondrium: this ſmall lobe is ſituated almoſt horizontally; the great lobe is very much inclined, and its thick extremity runs down almoſt in a perpendicular direction to the right kidney, on which it lies in the manner already ſaid. This obſervation is of uſe to diſtinguiſh the different parts of the liver, in wounds and chirurgical operations. It may likewiſe ſerve to direct us in examining a liver taken out of the body; the ſituation of which may be otherwiſe very eaſily miſtaken, eſpecially that of the parts of the concave ſide. The paſſage of the vena cava, between the body of the great lobe and the lobulus Spigelii, may likewiſe ſerve for a rule, in placing a detached liver in its true ſituation.

The liver is compoſed of ſeveral kinds of veſſels, the ramifications of which are multiplied in an aſtoniſhing manner and form, by the intertexture of their capillary extremities, an innumerable collection of ſmall, pulpy, friable corpuſcles, which are looked upon to be ſo many organs deſigned to ſeparate from the maſs of blood a particular fluid termed the bile. See the article BILE.

The greateſt part of theſe veſſels, from one end to the other, is included in a membranous vagina called capſula venæ portæ, or capſula Gliſſoni, from an Engliſh author who has deſcribed it particularly. The veſſel which carries the blood to the liver, is called the vena portæ, for the reaſon already given. In the deſcription of the veins it is obſerved, that the vena portæ might be conſidered as two large veins, the trunks of which are joined endwiſe, and ſend out branches and ramifications in oppoſite directions to each other; that one of theſe veins is ramified in the liver, the other lying without the liver, and ſending its branches and ramifications to the viſcera of the abdomen; and laſtly, that the firſt of theſe large veins may be termed vena portæ hepatica, the other vena portæ ventralis.

The particular trunk of the vena portæ hepatica is ſituated tranſverſely between the broad anterior eminence of the great lobe of the liver, and the root of the lobulus, in a particular ſciſſure, and forms what is called the ſinus of the vena portæ. From this ſinus five principal branches go out, which are afterwards divided into millions of ramifications, though the whole ſubſtance of the liver. At this place the vena portæ lays down the common office of a vein, and becomes a kind of artery, as it enters, and is again ramified in the liver. The extremities of all theſe ramifications of the trunk of the vena portæ hepatica end in the pulpy friable corpuſcles, which ſeen to be thick, villous folliculi, when examined through a microſcope in clear water.

It is in theſe folliculi that the bile is ſecreted, and it is immediately collected in the ſame number of extremities of another kind of veſſels, which unite by numerous ramifications into one common trunk. Theſe ramifications are termed pori biliarii, and the trunk ductus hepaticus; and the ramifications of theſe two kinds of veſſels are inveſted together by the capſula of the vena portæ.

The blood, deprived of this bilious fluid, is reconveyed to the heart, by a great number of venous ramifications, which afterwards unite into three principal branches, beſides others which are leſs conſiderable, that terminate in the vena cava, and are called by the name of venæ hepaticæ: the capillary extremities of the ramifications of the vena cava join thoſe of the vena portæ, and accompany them through the liver; and yet the great branches of both veins interſect each other in ſeveral places. When we cut the liver in ſlices, it is eaſy to diſtinguiſh, in each ſlice, the ramifications of the vena cava from thoſe of the vena portæ, the firſt being thinneſt and largeſt, and adhering cloſeſt to the ſubſtance of the liver; whereas thoſe of the vena portæ, which are inveſted by the cellular capſula, appear to be a little rumpled, when empty, becauſe the cellular capſula ſubſides, when it is cut; but the other veins remain uniformly open, their ſides adhering to the ſubſtance of the liver.

The liver receives from the cœliac artery a particular branch termed arteria hepatica, which being very ſmall, when compared with the bulk of that bowel, ſeems deſigned only for the nouriſhment thereof, and not for the ſecretion of the bile. The plexus hepaticus, formed by the nervi ſympathetici maximi and medii, furniſhes a great number of nerves to the ſubſtance of the liver. The ramifications of the artery, and nervous plexus, are included in the cellular capſula, together with thoſe of the vena portæ and pori biliarii: the pulſation of this artery has been, by ſome anatomiſts, taken for that of the capſula; and by this, they have endeavoured to explain the arterial function of the vena portæ: but they have not conſidered that the blood in this vein does not require to be pumped forward; becauſe ſo ſwift a motion would have been prejudicial to the ſecretion of the fine oil of the bile; for which a ſlow and almoſt an inſenſible motion is neceſſary. The liver is covered exteriorly by a particular membrane or coat, which is a continuation of the peritonæum: there is likewiſe a membranous or filamentary ſubſtance, which runs through the whole bowel, and connects the ramifications and extremities of all its veſſels to each other: this ſubſtance ſeems to be a complicated production of the capſula of the vena portæ, and of the external membrane of the liver. The outer ſurface of this coat is very ſmooth; but its inner ſurface is uneven, being made up of a great number of thin membranous laminæ, between which we obſerve, very diſtinctly, numerous lymphatic veſſels on both the convex and concave ſides of the liver; but it is more difficult to trace thoſe which accompany the filamentary ſubſtance through the bowel. We have already obſerved that the ſubſtance of the liver is principally made up of pulpy friable corpuſcles, each of which is bounded, and in a manner ſurrounded, by a particular expanſion of the capſula Gliſſoni; and all theſe expanſions are connected by common ſepta, in ſome meaſure reſembling a honey-comb: theſe corpuſcles have ſeveral angles eſpecially in the inner ſurface of the liver; but near the ſurface they are raiſed in the form of ſmall tubercles: their pulpy texture ſeems like radiated tufts, a ſmall void ſpace being left in the middle of each. If we blow through a pipe into the vena portæ, vena cava, arteria hepatica, or trunk of the pori biliarii, but eſpecially through the two veins, we obſerve the liver to ſwell, and the corpuſcles, near the ſurface, are raiſed and become more ſenſible: if blown with much force, theſe corpuſcles will burſt, and the air getting between them and the external membrane, raiſes it from the ſubſtance of the liver, in bliſters.

The ductus hepaticus or trunk of the pori biliarii, having run a little way, joins another canal, called ductus cyſticus or veſicularis, becauſe it comes from the veſicula felli: theſe two united trunks form a common trunk, named ductus communis choledochus, becauſe it conveys the bile: this duct, having reached the incurvation of the duodenum, inſinuates itſelf through the coats of that inteſtine, and opens into the cavity thereof, not by a round papilla, but by an oblong orifice, rounded at the upper part and contracted at the lower like the ſpout of an ewer, or like a common tooth-picker: the edges of this orifice are raiſed, broad, and plaited; as may be ſeen by making this portion of the duodenum ſwim in clear water: at the entry of this orifice, we may ſee another ſmaller opening, diſtinct from it, which is the orifice of the ductus pancreaticus.

Plate LXXX. *fig.* 4. exhibits the liver freed from its parenchyma.

Fig. 5. repreſents the flat part of the liver, together with the moſt conſpicuous veſſels in it, A being that part of the liver which lies next to the back; B, its right ſide; C, its anterior edge. D, its left ſide; E, the vena cava, where it paſſes through the diaphragm; E E 2, E 3, its three principal branches diſtributed almoſt through the whole liver; F, the vena portæ turned upwards, that other veſſels may be more eaſily ſeen; F F 2, F 3, F 4, four branches of the vena portæ diſtributed to ſeveral quarters of the flat part of the liver, but the fifth branch is not obſerved on this ſide; G, the gall bladder; H, H, the vena umbilicalis become a ligament; I, the ductus communis choledochus; K, the canalis venoſus, now performing the office of a ligament;

the trunk of the vena cava deſcendens; *a*, a ſmall portion of the membrane inveſting the liver; *b*, that part of the diaphragm which ſurrounds the vena cava; *c*, the biliary duct; *d*, the cyſtic duct; *e*, the place where theſe veſſels meet; *f*, the hepatic artery; *o*, *o*, the hepatic nerves, *p*, *p*, *p*, *p*, the common capſula laid open; *q*, *q*, the lymphæducts; *m*, *m*, *m*, &c. the ſmaller branches of the vena portæ; *n*, *n*, *n*, &c. the ſmall branches of the vena cava.

Fig. 6. repreſents the convex part of the liver, together with the veſſels ſituated in it. A, the ſuperior part of the liver which lies next to the back. B, its right part. C, its lower interior part. D, the left part of the liver. E, the trunk of the vena cava above the diaphragm. F, the ſinus of the vena portæ. F 1, F 2, F 3, F 4, four branches of the venæ diſtributed in four different directions through the liver. F 5, the fifth branch of the vena portæ, which could not be deſcribed in the preceding figure. G, the gall-bladder. H, H. the umbilical vein. I, the ductus communis choledochus. *a*, *a*, *a*, *a*, the ſmall ramifications of the fifth branch of the vena portæ cut off, that the other veſſels may be the more diſtinctly ſeen. *b*, that portion of the diaphragm where it is joined to the vena cava. *c*, the biliary duct. *d*, *d*, the cyſtic duct. *e*, the angle where thoſe veſſels are joined. *m*, *m*, *m*, &c. the ſmaller branches of the vena portæ. *n*, *n*, *n*, &c. the ſmaller branches of the vena cava.

Fig. 7. A, the convex part of the liver. B, its right part. C, the concave part of the liver. D, its left part. E, the trunk of the vena portæ turned upwards, that the other veſſels may be the more eaſily ſeen. 1, 2, 3, 4, 5, the five larger branches of the vena portæ. F, the ductus communis choledochus. G, the biliary duct and its firſt diviſion. H, the cyſtic duct. I, the gall-bladder. *a*, *a*, *a*, *a*, &c. the common capſula laid open. *b*, *b*, *b*, *b*, *b*, the ſubdiviſions of the biliary duct.

LIVERY *of Seiſin*, in law, ſignifies delivering the poſſeſſion of lands, &c. to him who has a right to them.

LIVERYMEN, of London, are a number of men choſen from among the freemen of each company. Out of this body the common council, ſheriff, and other ſuperior officers for the government of the city are elected, and they alone have the privilege of giving their votes for members of parliament; from which the reſt of the citizens are excluded.

LIVES, or *Inſurance of* LIVES. See the article INSURANCE and INTEREST.

LIVRE, a French money of account, containing twenty ſols.

LIXIVIOUS, *Lixiviate*, in chemiſtry, ſuch ſalts as are extracted from the aſhes of burnt vegetables by means of lotion.

LIXIVIUM, a ley, or water impregnated with the ſalts of burnt vegetables.

What is left after the evaporation of ſuch a liquor is called a lixivious ſalt.

Lixiviums are of great uſe in medicine, bleaching, ſugar-works, &c.

LIZARD, *Lacerta*, in zoology, a genus of amphibious animals, the body of which is oblong and rounded, the legs four, and the hinder part terminated by a tapering tail.

LOACH, the Engliſh name of a fiſh, called by Artedi, the ſmooth ſpotted cobitis, with a cylindrical body.

LOAD, among miners, denotes a vein of ore. See MINE.

It is alſo uſed for nine diſhes of ore. See the article DISH.

LOADSTONE, the ſame with magnet. See MAGNET.

LOAMS, in natural hiſtory, are defined to be earths, compoſed of diſſimilar particles, hard, ſtiff, denſe, and hard and rough to the touch; not eaſily ductile while moiſt, readily diffuſible in water, and compoſed of ſand, and a tough viſcid clay. Of theſe loams, ſome are whitiſh, and others brown or yellow.

LOBE, in anatomy, denotes each of the two parts of which the lungs conſiſt. See LUNGS.

It is alſo applied to the diviſions of the liver. The word is derived from the Greek λοβὸς, the extremity of a thing.

LOCAL, in law, ſomething fixed to the freehold, or tied to a certain place: thus real actions are local, ſince they muſt be brought in the country where they lie; and local cuſtoms are thoſe peculiar to certain countries and places.

LOCAL PROBLEM, among mathematicians, ſuch a one as is capable of an infinite number of different ſolutions, by reaſon that the point which is to reſolve the problem may be indifferently taken within a certain extent, as ſuppoſe any where, within ſuch a line, within ſuch a plane figure, &c. which is called a geometric locus, and the problem is ſaid to be a local or indetermined one. See LOCUS.

LOCHIA, in phyſic, the purgations of the uterus after child-birth. Theſe conſiſt, generally, for the two firſt days, of a kind of bloody ſerolity, and gradually become more white, viſcous, and leſs in quantity; which, during the whole time, cannot be determined, ſome women having more, others leſs: nor can the duration of the flux be limited to any particular time.

The lochia ſometimes flow in too large quantities, either on account of ſomething retained in the uterus, which prevents it from contracting duly; or a too great fluidity or agitation of the blood. If it proceed from a retention of ſomething in the uterus, this muſt, if poſſible, be taken away by the hand. But if it proceed from a too great fluidity or agitation of the blood, temperating decoctions of barley, jellies, emulſions, opiates, and aſtringents, are to be adminiſtered.

But when a deficiency in the lochia, or their utter ſuppreſſion, happens, all poſſible means ſhould be uſed to procure this ſalutary diſcharge. For this purpoſe mild anti-acids, diluters, and aperients, are to be exhibited. But great ſtreſs is to be laid on aperient and relaxing topics, clyſters, fomentations, plaſters, liniments, cupping on the inferior parts, peſſaries and ſuppoſitories.

Boerhaave adviſes not to let blood in the above-mentioned diſorders, without the utmoſt neceſſity.

LOCK, a well known inſtrument for ſecuring doors, cheſts, &c. and only to be opened by a key. See the article KEY.

LOCUS GEOMETRICUS, in geometry, denotes a line, by any point of which a local or indeterminate problem is ſolved.

If a right line ſuffice for the conſtruction of the equation, it is called locus ad rectam; if a circle, locus ad circulum; and theſe were called plain loci: if a parabola, hyperbola, locus ad parabolam, hyperbolam, &c. And thoſe were called ſolid loci.

Wolfius and the moderns more commodiouſly divide loci into orders, according to the number of dimenſions to which the indeterminate quantities riſe.

When in an equation there are two undetermined quantities *x* and *y*, then for each particular value of *x* there may be as many valves of *y* as it has dimenſions in that equation. So that if A P, a part of the indefinite line A E, repreſent *x*, and the perpendiculars P M (plate LXXXI. *fig.* 3.) repreſent the correſponding values of *y*, then there will be as many points M, the extremities of theſe perpendiculars or ordinates, as there are dimenſions of *y* in the equation. And the values of P M will be the roots of the equation ariſing by ſubſtituting for *x* its particular value A P in any caſe.

From whence it appears, how when an equation is given you may determine as many of the points M as you pleaſe, and draw the line that ſhall paſs through all theſe points; which is called the locus of the equation.

When any equation involving two unknown quantities, *x* and *y*, is propoſed, then ſubſtituting for *x* any particular value A P, if the equation that ariſes has all its roots poſitive, the points M will lie on one ſide of A E; but if any of them are found negative, then theſe are to be ſet off on the other ſide of A E towards *m*.

If for *x*, which is ſuppoſed undetermined, you ſubſtitute a negative quantity, as A *p*, then you will find the points M, *m*, are taken in, that it may ſhew all the values of *y* correſponding to all the poſſible values of *x*.

If, in any caſe, one of the values of *y* vaniſh, then the

point M coincides with P, and the locus meets with A E in that point.

If one of the values of y becomes infinite, then it ſhews that the curve has an infinite arch: and in that caſe the line P M becomes an aſymptote to the curve, or touches it at an infinite diſtance, if A P is itſelf finite.

If, when x is ſuppoſed infinitely great, a value of y vaniſh, then the curve approaches to A E produced as an aſymptote. If any values of y become impoſſible, then ſo many points M vaniſh.

From what has been ſaid it appears, that when an equation is propoſed involving two undetermined quantities, x and y, there may be as many interſections of the curve, that is the locus of the equation, and of the line P M, as there are dimenſions of y in the equation; and as many interſections of the curve and the line A E as there are dimenſions of x in the equation.

LOCUST, *Locuſta*, a genus of inſects, comprehending the locuſt, ſimply ſo called, the ſeveral ſpecies of other locuſts and graſhoppers, with the crickets of the houſe and field.

Willughby obſerves, that in theſe animals there are always more males than females, which is contrary to the order of nature in other inſects, where the females are much the moſt numerous; and Swammerdam obſerves, that it is only the males that make a noiſe, which he ſays they do by a ſwift vibration of their wings, either againſt one another, or againſt their legs.

The nympha, or worm of the locuſt, ſcarce at all differs from the creature in its perfect ſtate. It moves and eats in the nymph ſtate, and all the viſible difference is, that the wings are not expanded as in the perfect locuſt, but are gathered up in a ſmall compaſs, and form four little buttons on the ſhoulders. Swammerdam obſerves, that the want of attention to this particular, in former writers, had been the occaſion of a very unneceſſary multiplication of names; as Aldrovand, Johnſon, Mouffet, and others, have deſcribed theſe locuſts in the nymph ſtate under the names of bruchi, attebali, and aſelli, ſuppoſing them to be ſo many diſtinct ſpecies of animals. It is obſerved, that towards the end of ſummer the males are very tender of the females, three or four of them being frequently ſeen gathered about one of that ſex, and ſeeming to do her all the kind offices in their power, fluttering about with their wings, and rubbing her with their fore legs. The males are always more briſk and nimble than the females; and, amongſt all the kinds of locuſts, there are a great many naturally imperfect; particularly, many have only one hinder leg, yet theſe hop almoſt as well as the reſt.

The country of the Coſſacks or Ukrain is, in dry ſummers, much infeſted with ſwarms of locuſts driven thither by an eaſt or ſouth-eaſt wind. The number of theſe inſects is ſo great, that they darken the air, and devour all the corn of the country. They lay their eggs in autumn, and then die. It is ſaid that each of theſe creatures lays two or three hundred eggs, which hatching the enſuing ſpring, produce ſuch a number of locuſts, that they do far more miſchief than before, unleſs the rains fall, which kill both the eggs and the inſects, or unleſs a ſtrong north or north-weſt wind ariſes, which drives all into the Euxine ſea. The hogs of the country are fond of theſe eggs, and devour great quantities of them. In the night, when theſe inſects reſt on the ground, they cover it to the height of three or four inches. If a wheel paſſes over them, they emit an intolerable ſtench. *Phil. Tranſ.* N°. 8.

Water LOCUST, *Locuſta Aquatica*, the name given by authors to a ſpecies of water inſect, ſomewhat reſembling the locuſt kind in ſhape. It is about three inches long, its tail an inch and a quarter, and its legs are of different lengths; the anterior pair being ſhorteſt of all. Its body is ſlender, and its fore legs are always carried ſtraight forward, ſo as to reach beyond the head in the form of antennæ. Theſe, as well as the other legs, end each in two claws. The eyes are ſmall and not very prominent, and the upper wings are cruſtaceous, the under ones membranaceous, thin, and tranſparent. The middle joint of the leg is ſuch, that the creature can only move them upwards, not downwards; and there runs an acute tongue or proboſcis under the belly, as is the caſe of the water ſcorpion and notonecta. *Ray's Hiſt. Inſects.*

LOCUSTÆ, in botany, the tender extremities of the branches of trees, ſuch as, it is ſuppoſed, St. John Baptiſt fed on in the wilderneſs.

LODGMENT, in military affairs, is a work raiſed with earth, gabions, faſcines, wool-packs, or mantelets, to cover the beſiegers from the enemy's fire, and to prevent their loſing a place which they have gained, and are reſolved, if poſſible, to keep. For this purpoſe, when a lodgment is to be made on the glacis, covert-way, or in a breach, there muſt be great proviſion made of faſcines, ſand-bags, &c. in the trenches; and during the action, the pioneers with faſcines, ſand-bags, &c. ſhould be making the lodgment, in order to form a covering in as advantageous a manner as poſſible from the oppoſite baſtion, or the place moſt to be feared.

LOG, in naval affairs, a ſmall triangular piece of board uſed on board a ſhip; into one end of which a convenient quantity of lead is caſt, to make it ſwim upright, the other end being faſtened to the log-line.

LOG-LINE, a line faſtened to one end of the log, and wound upon a reel.

This line is generally divided into certain ſpaces, which are, or ought at leaſt to be, ſuch a proportional part of a nautical mile, ſixty of which make a degree of a great circle, as half a minute, the time allowed for the experiment, is of an hour. Now a common nautical or ſea mile, according to an experiment made by Mr. Richard Norwood, and with which the French nearly agree, is=6120 Engliſh feet, which being divided by 120, the half minutes in an hour, gives fifty-one feet for the diſtance between each diviſion on the log-line.

Theſe diviſions or ſpaces are called knots, becauſe at the end of each diviſion there is a piece of twine with knots in it reeſed between the ſtands of the line: whereby the number of diviſions or knots run off the reel, during the half minute, are readily counted.

And becauſe it is requiſite that the log be out of the eddy of the ſhip's wake before they begin to count, therefore theſe knots or ſpaces begin at the diſtance of ten fathoms or ſixty feet from the log, at which point, for the more ready diſcovering it, there is faſtened a piece of red rag.

The log-line being thus prepared and wound upon a reel, heave the log over-board from the poop, and as ſoon as the log is out of the ſhip's eddy, or the red rag at your hand, let your aſſiſtant turn the half minute glaſs; then veer the line from off the reel, which eaſily turns, as the ſhip ſails from the log, till the half minute glaſs is run out, at which time ſtop the line, and the number of knots intercepted between your hand and the red rag, will ſhew how far the ſhip has run in that time, and, conſequently, her rate of ſailing. For ſince the diſtance, comprehended between each knot, bears the ſame proportion to a nautical mile as half a minute does to an hour; therefore as many knots as are run out in half a minute, ſo many miles will the ſhip ſail in an hour; ſuppoſing her to move with the ſame velocity, during that time.

But as many accidents attend a ſhip during a day's ſailing, ſuch as the variableneſs of winds, the different quantity of ſail carried, &c. it will be neceſſary to heave the log at every alteration; but if none of theſe alterations be perceptible, yet it ought to be conſtantly heaved, at leaſt every hour. As the log-line is apt to ſtretch and ſhrink, and the half minute glaſs to alter, they ought to be often examined, and when found amiſs, rectified.

The generality of our ſeamen, upon a ſuppoſition that ſixty Engliſh miles are equal to a degree of a great circle, make the diſtance between knot and knot but forty feet; but as this ſuppoſition is evidently falſe, it were greatly to be wiſhed that they woud conſtantly uſe the former limitation, being in every reſpect as eaſy, and much more ſure and certain; and the rather, as they are at the ſame time obliged by experience to ſhorten the half minute glaſs nearly four ſeconds, which is nothing leſs than correcting one blunder by another.

LOG-

Log-Board, a table generally divided into five columns, in the firſt of which is entered the hour of the day; in the ſecond, the courſe ſteered; in the third, the number of knots ran off the reel each time of heaving the log; in the fourth, from what point the wind blows; and in the fifth, obſervations on the weather, variation of the compaſs, &c.

Log-Book, a book ruled in columns like the log-board, into which the account on the log-board is tranſcribed every day at noon; from whence, after it is corrected, &c. it is entered into the journal.

Log-Wood, or Campeachy wood, is the wood of a low prickly tree, which grows plentifully about Campeachy on the bay of Honduras. See Campeachy-Wood.

Log-wood gives out its colour both to watery and ſpirituous menſtrua, but not readily to either: it requires to be raſped and ground into fine powder, and boiled in ſeveral freſh parcels of the liquors. Rectified ſpirit extracts the colour more eaſily, and from a larger proportion of the wood than water does.

The tinctures both in water and in ſpirit are of a fine red, with an admixture, particularly in the watery one, of a violet or purple. Volatile alkaline ſalts or ſpirits incline the colour more to purple: the vegetable and nitrous acids render it pale; the vitriolic and marine acids deepen it.

The watery decoction, wrote with on paper, loſes its redneſs in a few days, and becomes wholly violet. This colour communicates alſo to woollen cloth previouſly prepared by boiling with a ſolution of alum and tartar: the dye is beautiful, but very periſhable. It is often uſed by the dyers, as an ingredient in compound colours, for procuring certain ſhades which are not eaſily hit by other materials.

With chalybeate ſolutions, it ſtrikes a black. Hence it is employed in conjunction with thoſe liquors, for ſtaining wood black for picture frames, &c. and with the addition of galls, for dyeing cloth and hats black. The black dyes, in which this wood is an ingredient, have a particular luſtre and ſoftneſs, far beyond thoſe made with galls and vitriol alone: the beauty, however, which it here imparts, is not permanent, any more than its own natural violet dye.

On the ſame principle, it improves alſo the luſtre and blackneſs of writing ink. Ink made with vitriol and galls, does not attain to its full blackneſs till after it has lain ſome time upon the paper: a due addition of log-wood renders it of a deep black as it flows from the pen, eſpecially when vinegar or white wine is uſed for the menſtruum.

LOGARITHMIC *Curve*, a curve which explains the nature and properties of logarithms, and is delineated in the following manner:

Upon the line A G (plate LXXXI. *fig.* 4.) infinitely extended each way, let there be taken A B, B C, C D, D E, E F, &c. towards the right hand; alſo A O, O P, &c towards the left, all equal among themſelves; and from the ſeveral points P, O, A, B, C, D, E, F, &c. let there be drawn the lines R P, O Q, A H, B I, C K, D L, E M, F N, &c. equal in length to the ſeveral lines, in the geometrical ſcale of proportional lines, infinite in number; theſe therefore will repreſent ſo many terms in the progreſſional of proportionals, of which the line A H repreſents unity. Now if the extremities R, Q, H, I, K, L, M, N, &c. of the geometrical ſcale of mean proportionals be connected together by right-lines, the figure P R N F will be a polygon, conſiſting of more or fewer ſides, according as the terms in the ſcales of mean proportionals are more or fewer in number.

If the diſtances A B, B C, D E, E F, &c. are biſſected in the points *b*, *c*, *d*, *e*, *f*, &c. and from theſe points be drawn lines, as *b i*, *c k*, *d l*, *e m*, *f n*, &c. perpendicular to A G, which will be ſo many proportionals between A H, B I, C K, D L, E M, F N, &c. there will ariſe a new ſcale for a ſeries of proportionals between A H, B I, C K, D L, E M, F N, &c. double in number to thoſe of the former ſcale. And if the extremities H, *i*, I, *k*, K, *l*, L, &c. be connected together by right-lines, we ſhall have a new polygon, conſiſting of a greater number of ſides; but each ſide leſs in magnitude.

After the ſame manner, if the diſtance between every two terms be continually biſſected, and to each of the points, ſo found, there be applied a ſeries of mean proportionals, the number of terms in this new ſcale, as alſo the ſides of the polygon, will by this means become infinite; and each ſide of the polygon will be leſs than any given right-line, and conſequently the polygon will be changed into a curve-lined figure; ſince every curvilinear figure may be conſidered as a polygon of an infinite number of ſides. The curve thus deſcribed is called the logarithmic curve, in which, if the right-lines A H, B I, &c. which ſtand at right-angles to the axis A G, repreſent ſo many terms in a ſeries of numbers in geometrical progreſſion, the portions of the axis A B, B G, &c. between the place of unity and any given term, will ſhew the place or order that each number in the ſcale of geometrical proportionals obtains from the place of unity in the ſame ſeries.

The diſtance therefore between any two numbers, in this continued ſcale of geometrical proportionals, is the logarithm of the ratio of theſe two numbers the one to the other. See Logarithms.

Logarithmic *Spiral*. If the quadrant of a circle A N B (plate LXXXI. *fig.* 5.) be divided into any number of equal parts, in the points N, *n*, *n*, &c. and from the radii C N, C *n*, C *n*, &c. be cut off C M, C *m*, C *m*, &c. continual proportionals, the points M, *m*, *m*, *m*, &c. will be in the logarithmic ſpiral. And there may be imagined an infinite number of different curves of this kind.

LOGARITHMS, a ſet of artificial numbers, whereby the common operations in multiplication and diviſion are performed by addition and ſubtraction; raiſing powers and extracting roots, are by the help of theſe numbers eaſily performed by multiplication and diviſion.

The word is formed from the Greek, λογος, ratio, and αριθμος, number.

Logarithms, juſtly eſteemed one of the greateſt and moſt uſeful diſcoveries that the laſt century has produced, were firſt invented by John Neper, baron of Marchiſton in Scotland, and by him firſt publiſhed at Edinburgh in the year 1614, and ſoon after by himſelf, and Mr. Briggs, (then Savilian profeſſor of geometry in the univerſity of Oxford) reduced into a better form, and publiſhed in London in the year 1624, in the ſame form and manner as they are uſed at this day.

Logarithms may be conſidered as, and are uſually defined to be, a ſeries or rank of numbers in an arithmetical progreſſion, fitted or adapted to the exponents of a ſeries of numbers in a geometrical progreſſion.

If between 1 and x be inſerted a mean proportional, which is $\sqrt{x}$ or $x^{\frac{1}{2}}$, its index $\frac{1}{2}$ ſhews that its diſtance from unity will be but one half of the diſtance of x from unity. In like manner, if between x and x^2 we inſert a mean proportional, its index will be 1 and $\frac{1}{2}$ or $\frac{3}{2}$, inaſmuch as its diſtance from unity is once and a half the diſtance of x from the ſame place of unity.

Again, if between 1 and x be inſerted two mean proportionals, the firſt of theſe will be the cube-root of x or $\sqrt[3]{x}$, and its index will be $\frac{1}{3}$, inaſmuch as its diſtance from the units place is but $\frac{1}{3}$ of the diſtance of x, from the ſame place of unity; and conſequently $\sqrt[3]{x}$ is expreſſed by $x^{\frac{1}{3}}$, whence it follows that the index of unity is 0, inaſmuch as unity cannot be removed at any diſtance from itſelf.

And the ſame ſeries of geometrical proportionals may be continued on the contrary ſide of unity, or towards the left hand, and which therefore will decreaſe in the ſame manner, or in the ſame ratio, as the terms placed on the right hand increaſe.

For the terms $\frac{1}{x^5}$, $\frac{1}{x^4}$, $\frac{1}{x^3}$, $\frac{1}{x^2}$, $\frac{1}{x}$, 1, x, x^2, x^3, x^4, x^5, &c. are in the ſame geometrical progreſſion continued, and have all the ſame common ratio; wherefore, inaſmuch as the diſtance of x from unity towards the right hand is poſitive, or $+1$, the diſtance of $\frac{1}{x}$ from unity towards the left hand, which is equal to the former, is

is negative or -1, which is therefore the index of $\frac{1}{x}$, and consequently for $\frac{1}{x}$ may be written x^{-1}.

Again, inasmuch as x^2 is on the right side of unity, and positive, and its index $+2$, the index of $\frac{1}{x^2}$, which is as far distant from unity on the contrary side, or towards the left hand, will be negative, and -2, and consequently $\frac{1}{x^2}$ is the same with x^{-2}: In like manner x^{-3} is the same with $\frac{1}{x^3}$, and x^{-4} same with $\frac{1}{x^4}$; whence it comes to pass that the negative indices shew that the terms to which they belong, are as far distant from unity toward the left hand, as the terms whose indices are the same and positive, are removed from unity on the contrary side, or towards the right hand.

Again, as between 1 and x, in the series increasing from or on the right hand of unity, may be inserted a mean proportional as $\sqrt{x}$, and between this mean proportional and unity be inserted another mean proportional as $\sqrt[4]{x}$, and between the last mean proportional and unity be inserted another mean proportional as $\sqrt[8]{x}$, &c. whose respective indices will be $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, &c. so between unity and the next term $\frac{1}{x}$ in the series decreasing from unity, or on the left hand of unity, may be inserted a mean proportional as $\frac{1}{\sqrt{x}}$, whose correspondent index will be $-\frac{1}{2}$: and, again, between this mean proportional and unity, may another mean proportional, as $\frac{1}{\sqrt[4]{x}}$, be inserted, whose correspondent index will be $-\frac{1}{4}$, and between this and unity may another mean proportional be inserted; the index will be $-\frac{1}{8}$, &c. and as this may be done between any other two terms of the progression, it follows, that between any two terms may an infinite number of mean proportionals be inserted, whose respective indices will become the logarithms of the respective terms to which they belong: and these mean proportionals, the greater they are in number between the two terms of any ratio, the nearer do they approach to a ratio of equality, with their correspondent indices or exponents.

Hence we are let into the reason of the ancient way of making logarithms, and which was made use of by their first inventors, and that was by a continual extraction of the square-root. In order to this, they first extracted the square of 10, and having continued that root to a very great number of places, they extracted the square-root again, and so on continually until they at last, after 54 such extractions, obtained the number 1,000000000000000127819149320032344 2. Now if this number be first squared, then cubed, then raised to the fourth, fifth, &c. power, it is very certain that, as their increase in the several products arise but by slow degrees, there will among them be found such as are extremely near in value to the natural numbers 2, 3, 4, 5, &c. and consequently, by what has been already said concerning the nature of logarithms, those of the natural numbers 2, 3, 4, 5, &c. will be expounded by the exponents, or number of multiplications, which formed the products respectively equal (or nearly so) to the natural numbers 2, 3, 4, 5, 6, &c. Here we see the reason why the logarithm of 1 is 0, or rather, that 1 has no logarithm, because the quantity to be continually involved must be a small matter greater than 1; for if it be less, the powers will decrease it.

If logarithms are to be made only to seven places of figures, which are sufficient for common use, twenty-five successive extractions will do for that purpose; that is, we need only extract the 33554432 (or 2 raised to the 25th power) root of 10; because in that root there will be found seven cyphers before the first significant figure after the unit; and in the course of these extractions, the denominators of the fractions expounding those roots which are nearest in value to any of the natural numbers 2, 3, 4, 5, &c. will point out their respective logarithms.

Some have considered the logarithm of a number as the logarithm of the ratio of unity to that number itself, or as the distance between unity and that number in a geometrical scale of proportionals, and consequently measured by the number of proportionals contained between them: logarithms therefore expound the place or order that every number obtains from the unit's place in a continued series or scale of proportionals indefinite in number.

Thus, if between unity, and the number 10, there be supposed 10000000, &c. mean proportionals, that is, if the number 10 be placed in the 10000000th place from unity, between 1 and 2, there will be found 3010300 of such proportionals; that is, the number 2 will be placed in the 3010300th place from unity; between 1 and 3 there will be found 4771213 of the same proportionals, or the number 3 will stand in the 4771213th place in the indefinite scale of proportionals; their numbers 10000000, 3010300, and 4771213, are therefore the logarithms of 10, 2, and 3; or, more properly, the logarithms of the ratio's of those numbers one to the other.

Again, if between unity and the number 10, there be supposed an indefinite scale of mean proportionals, whose number is 23025851; that is, if the number 10 be placed in the 23025851st place from unity, in the indefinite scale of proportionals, between 1 and 2, there will be found to be 6931471 such mean proportionals; and between 1 and 3, there will be found 10986122 of the same proportionals: so that if the first term of the series be called x, the second term will be x^2, the third x^3, &c. and if the number 10 be supposed to be the 10000000th term in the series, the number 2 will be the 3010300th term, and the number 3 will be the 4771213th term in the same series; and consequently $x^{10000000} = 10$, $x^{3010300} = 2$, and $x^{4771213} = 3$, &c. and again, if the number 10 be supposed the 23025851st term in the series, the number 2 will be the 6931471st term, and the number 3 the 10986122d term in the same series; and consequently, in this case, $x^{23025851} = 10$, $x^{6931471} = 2$, and $x^{10986122} = 3$, &c.

And as the indefinite number of mean proportionals between any two numbers may be assumed at pleasure, hence logarithms may be of as many different forms (that is, there may be as many different scales of logarithms) as there can be assumed different scales of mean proportionals between any two numbers. Every number therefore is some certain power of that number which is placed next to unity in the indefinite scale of proportionals between unity and the given number, and the index of that power is the logarithm of the number.

Logarithms therefore may be of as many sorts as you can assume different indices of the power of that number whose logarithm is required.

But since fluxions and the higher geometry have been so well understood, mathematicians have directed their views towards facilitating those laborious and operose calculations formerly made use of for constructing tables of logarithms, by help of converging series, and other means, whereby the logarithms of any proposed numbers may now be obtained with very little trouble: an example of this kind may be seen in Mac Laurin's Fluxions, p. 678, vol. ii. where that celebrated mathematician shews that, the logarithm of m being given, the logarithm of $\overline{m+z}$ — log. m is equal to $\frac{2z}{2m+z}$ multiplied by the series $1 - \frac{z}{12} \times \frac{1}{m+z} - \frac{1}{m} + \frac{z^3}{360} \times \frac{1}{\overline{m+z}^3} - \frac{1}{m^3} - \frac{z^5}{1260} \times \frac{1}{\overline{m+z}^5} - \frac{1}{m^5}$ + &c. This series converges so very swift, that two or three terms are sufficient in almost any case whatsoever.

The indices, or characteristics of logarithms, correspond to the denominative part of the natural numbers, as the other member of the logarithm does to the denominative part of the number: that is, the index shews the denomination, or place of the last (or left hand) figure of the number, and consequently of all the rest. — Thus 0 affixed to a logarithm, denotes the last figure of the number, to which the logarithm answers, to be nothing distant

diſtant from (i. e. in) the place of units. The index 1 ſhews the laſt figure of its number to be diſtant 1 place from the place of units, i. e. to be in the place of tens, and conſequently the number itſelf to be either 10, or ſome number between that and 100, and ſo of the other indices.—Hence all numbers, which have the ſame denomination, but not the ſame numerative parts, are all numbers from 1 to 10, from 10 to 1000, &c. and will have logarithms whoſe indices are the ſame, but the other members different. Again, all numbers, which have the ſame numerative, but not the ſame denominative part, will have different indices, but the reſt of the logarithms the ſame. If a number be purely decimal, to its logarithm is affixed a negative index, ſhewing the diſtance of its firſt real figure, from the place of units. Thus the logarithm of the decimal ,256 is $\bar{1}$,43824; of the decimal ,0256 is $\bar{2}$ 30824, &c.

To find the logarithm for a number greater than any in the common tables, but leſs than 10000000.—Cut off four figures on the left hand of the given number, and ſeek the logarithm in the table; add as many units to the index, as there are figures remaining on the right; ſubtract the logarithm found from the next following it, in the table; then, as the difference of numbers in the canon is to the tabular difference of the logarithms anſwering to them, ſo are the remaining figures of the given number to the logarithmic difference; which if it be added to the logarithm before found, the ſum will be the logarithm required. Suppoſe the logarithm of the number 92375 were required. Cut off the four figures 9237, and to the characteriſtic of the logarithm correſponding to them, add an unit; then

From the logarith. of the numb. 9238 =	3,9655780
Subtract logarith. numb. — — 9237 =	3,9655309
Remains tabular difference — — — —	471

10—471=5
5) 2 — — 1
235

Now to the logarithm — — —	4,9655309
Add the difference found — — —	235
The ſum is the logarithm required —	4,9655544

To find the logarithm of a proper fraction.—Subtract the logarithm of the numerator from that of the denominator, and to the remainder prefix the ſign of ſubtraction.—Thus ſuppoſe it were required to find the logarithm of $\frac{3}{7}$,

Logarithm of 7 =	0,8450980
Logarithm of 3 =	0,4771213
Logarithm of $\frac{3}{7}$ =	$\bar{0}$,3679767

To find the number correſponding to a logarithm greater than any in the table.—Firſt, from the given logarithm, ſubtract the logarithm of 10, or 100, or 1000, or 10000, till you have a logarithm that will come within the compaſs of the table; find the number correſponding to this, and multiply it by 10, or 100, or 1000, or 10000, the product is the number required. Suppoſe, for inſtance, the number correſponding to the logarithm 7,7589982 be required; ſubtract the logarithm of the number 10000, which is 4,0000000, from 7,589982; the remainder is 3,7589982, the number correſponding to which is 5741,1, which multiplied by 10000, gives 57411000, the number required.

To find the number correſponding to a negative logarithm.—To the given negative logarithm, add the laſt logarithm of the table, or that of the number 10000, i. e. ſubtract the firſt from the ſecond, and find the number correſponding to the remainder; this will be the numerator of the fraction, whoſe denominator will be 10000. Suppoſe it be required to find the fraction correſponding to the negative logarithm 0,3679767, ſubtract this from

4,0000000

the remainder is — — 3,6320233, the number correſponding to which is 4285 $\frac{71}{100}$; the fraction ſought therefore is $\frac{4285\frac{71}{100}}{10000}$.—The reaſon of the rule is, that as a fraction is the quotient, ariſing from the diviſion of the numerator by the denominator, unity will be to the fraction, as the denominator to the numerator; but as unity is to the fraction correſponding to the given negative logarithm, ſo is 10000 to the number correſponding to the remainder: therefore if 10000 be taken for the denominator, the number will be the numerator of the fraction required.

To find a fourth proportional to three given numbers, add the logarithm of the ſecond to that of the third, and from the ſum ſubtract the logarithm of the firſt; the remainder is the logarithm of the fourth required. Let the given numbers be 4, 68, and 3.

Logarithm 68 =	1,8325089
Logarithm 3 =	0,4771213
Sum — — =	2,3096302
Logarithm 4 =	0,6020600
Logarithm requir'd	1,7075732

The number in the tables correſponding to which is 51.

LOGIC, λογικὴ, the art of thinking and reaſoning juſtly; or, it may be defined the ſcience or hiſtory of the human mind, inaſmuch as it traces the progreſs of our knowledge from our firſt and moſt ſimple ideas thro' all their different combinations, conceptions, and all thoſe numerous deductions that reſult from variouſly comparing them one with another. See the articles IDEA and KNOWLEDGE.

The preciſe buſineſs of logic, therefore, is to explain the nature of the human mind, and the proper manner of conducting its ſeveral powers, in order to the attainment of truth and knowledge. It lays open thoſe errors and miſtakes we are apt, through inattention, to run into; and teaches us how to diſtinguiſh between truth, and what only carries the appearance of it. By this means we grow acquainted with the nature and force of the underſtanding; ſee what things lie within its reach; where we may attain certainty and demonſtration; and when we muſt be contented with probability.

Theſe conſiderations ſufficiently evince the uſefulneſs of this ſcience, which is divided into four parts, according to the number of the operations of the mind in its ſearch after knowledge, viz. perception, judgment, reaſoning, and method. See the articles PERCEPTION, &c.

This valuable art of ranging our ideas, connecting them cloſely together, and conſequently of facilitating the tranſition from one to another, ſupplies us with a means of rendering all men's abilities nearly equal. In fact, all our knowledge is reducible to primitive ſenſations, which is nearly alike in all men. The art of combining and connecting our direct ideas only gives them a more or leſs exact arrangement and denomination; whence they become more or leſs ſenſible to others. A man who readily combines his ideas, differs but little from him who combines them ſlowly; as he who judges of a picture at ſight, differs but little from him who requires to be made ſenſible of all its parts: both at the firſt glance have the ſame ſenſations, though they ſink not ſo deep in the ſecond, who therefore dwells longer upon each, to render them ſtrong and diſtinct; and by this means, the reflex ideas of the firſt obſerver become as eaſy to the ſecond as direct ones. And hence, perhaps, there is ſcarce an art or ſcience that may not, by means of a well adapted logic, be taught to a ſlow underſtanding; becauſe there are few arts or ſciences, whoſe precepts or rules may not be reduced to ſimple notions, and diſpoſed in ſo connected an order, that the chain need never be broken. As the mind is more or leſs ſlow in its operations, it requires more or leſs of this connected order. The advantage of a genius is that of having leſs occaſion for it; or rather, of being able to form it quick and almoſt imperceptibly. See DEMONSTRATION.

LOGISTIC CURVE, the ſame with that otherwiſe called logarithmic. See the article LOGARITHMIC.

LOGISTIC SPIRAL. See LOGARITHMIC and SPIRAL.

LOGISTICA NUMERALIS, the ſame with algorithm. See ALGORITHM.

LOGISTICAL ARITHMETIC, the doctrine of ſexageſimal fractions. See the article SEXAGESIMAL.

LOHOCH, or LOCH, in pharmacy, a compoſition of a middle conſiſtence between a ſoft electuary and a ſyrup, principally uſed in diſorders of the lungs. See LINCTUS.

LOINS, *Lumbi*, in anatomy, the two lateral parts of the

the umbilical region of the abdomen. See the article ABDOMEN.

LOLIUM, darnel, in botany, a genus of plants, the corolla whereof conſiſts of two valves; the lower is narrow, lanceolated, convoluted, acuminated, and of the length of the cup; the other is ſhort, linear, obtuſe, and hollowed upwards; there is no pericarpium, the corolla incloſes the ſeed, which is ſingle, oblong, compreſſed, convex on one ſide, and plane and ſulcated in the middle on the other.

The ſeed of this plant is reckoned attenuant, abſtergent, drying and heating.

LOMBARDY, a kingdom which comprehended almoſt all Italy. It was erected by the Longobards, or Lombards, a German nation, about the year 598, and laſted till Charlemain put an end to it, about the year 760.

LONCHITIS, ſpleenwort, in botany, a genus of plants, the fructifications of which are arranged into lunulated ſeries, and diſpoſed ſeparately under the ſinuſes of the leaves.

The leaves of this plant are of uſe in healing wounds, and in preventing inflammations of them; they are alſo uſed againſt the ſpleen; the root is aperient and diuretic.

LONDON, the metropolis of Great Britain, where the firſt meridian is fixed on the Britiſh maps, lies in 51° 32′ north latitude, on the river Thames, and the greateſt part on the north-ſide of that river. The form of London, including Weſtminſter and Southwark, comes pretty near an oblong ſquare, five miles in length, if meaſured in a direct line from Hyde-Park to the end of Limehouſe, and ſix miles, if we follow the windings of the ſtreets; the greateſt breadth is two miles and a half; and the circumference of the whole ſixteen or ſeventeen miles, but it is not eaſy to meaſure it exactly, on account of its irregular form. The principal ſtreets are generally level, exceeding well built, and extended to a very great length; theſe are inhabited by tradeſmen, whoſe houſes and ſhops make a much better figure than thoſe of any tradeſmen in Europe. People of diſtinction uſually reſide in elegant ſquares, of which there are great numbers at the weſt end of the town near the court. What moſtly contributes to the riches and glory of this city, is the port, whither ſeveral thouſand ſhips of burden annually reſort from all countries, and where the greateſt fleets never fail to meet with wealthy merchants ready to take off the richeſt cargoes. The number of people in the whole city are computed to be about one million.

LONGÆVITY, from *longus*, long, and *vita*, life, length of life.

We have ſeveral inſtances of longævity, as Parr, who lived one hundred and thirty-two years and nine months; Henry Jenkins of Yorkſhire, who lived one hundred and ſixty-nine; the counteſs of Deſmond and Mr. Eccleſtone, both of Ireland, each of whom exceeded one hundred and forty years.

LONG-BOAT, in the marine, the largeſt and ſtrongeſt boat in the ſhip.

The uſe of the long-boat is to carry great bins, ſuch as water, proviſions, anchors, and cables, and often part of the cargo: ſhe is occaſionally equipped with a maſt, ſails, and rigging, ſometimes armed with ſwivels, muſketoons, and carabines, and can be decked as neceſſity requires.

LONGIMETRY, the art of meaſuring lengths, acceſſible and inacceſſible.

LONGISSIMUS DORSI, in anatomy, a very complex, long and narrow muſcle ſituated between the ſpinal apophyſes and the ſacro-lumbaris, from which it is divided by a fatty or cellular line; but, at the lower part, they are confounded together. It covers the ſemiſpinalis or tranſverſo-ſpinalis dorſi, and ſemiſpinalis lumborum. Its upper part lies between the ſacro-lumbaris and tranſverſalis colli. This muſcle and the ſacro-lumbaris are common to the back and loins. The longiſſimus dorſi is an aſſiſtant to the ſacro-lumbaris, eſpecially its vertebral portion, which it helps very powerfully both by the multiplicity and inſertions of its fibres, in ſuſtaining the vertebræ of the back and loins, while extended, whether in ſitting or ſtanding, and in preventing their ſinking under the weight of the body, or any additional burden. It aſſiſts in performing, or counterballancing all the motions and inflections which theſe vertebræ, eſpecially thoſe of the loins, are capable of in all poſtures of the body. And in this, it alſo bears ſome reſemblance to the inferior or vertebral portion of the ſplenius: and theſe two muſcles on each ſide, and the ſacro-lumbaris, are of the number of thoſe called vertebrales obliquæ divergentes. *Winſlow's Anat.*

LONGITUDE *of the Earth*, denotes its extent from weſt to eaſt, according to the direction of the equator.

LONGITUDE *of a Star*, &c. in aſtronomy, an arch of the ecliptic, counted from the beginning of aries, to the place where a ſtar's circle of longitude cuts the ecliptic.

LONGITUDE *of a Place*, in geography, its diſtance from ſome firſt meridian, or an arch of the equator intercepted between the meridian of the place and the firſt meridian.

LONGITUDE, in navigation, the diſtance of a ſhip or place, eaſt or weſt, from one another, counted in degrees of the equator. If this diſtance be counted in leagues, miles, &c. or in degrees of the meridian, and not in thoſe proper to the parallel of latitude, it is uſually called departure.

Since the difference of longitude between any two places is equal to the arch of the equator intercepted between the two meridians paſſing through the two places; which is analogous to the quantity of time that the ſun requires to move from the meridian of one place to that of another; or, in the language of the Copernicans, that is elapſed between the application of the meridian of one of the places to the ſun and the meridian of the other; for ſince the ſun finiſhes his diurnal revolution in the ſpace of 24 hours, or, which is the ſame thing, ſince the revolution of the earth about her axis is performed in the ſame time; it follows that in every hour there paſſes over the meridian one twenty-fourth part of 360 degrees, or of the whole circumference of the equator, equal to fifteen degrees; in two hours, one twelfth part, or thirty degrees; and, in any greater or leſſer part of time, a proportional greater or leſſer part of the equator; whence it follows, that if the difference of longitude, or arch of the equator intercepted between the meridians paſſing through any two places, be known, the difference of the times of the day in thoſe two places is known alſo; and conſequently, the hour in one place being known, the hour in the other place is known alſo; and, on the contrary, if the difference between the times at any two places be known, the difference of longitude between thoſe two places is known alſo, by reducing the difference of the times into degrees and minutes, allowing fifteen degrees to an hour, &c.

Hence it is, that if two or more places lie under the ſame meridian, the hour in one will be the ſame with the hour in the other; and, on the contrary, if in two or more places the hour be the ſame, thoſe places lie under the ſame meridian.

And, becauſe the ſun in all places conſtantly riſes in the eaſt, he muſt neceſſarily apply himſelf to the meridian of the eaſtermoſt place firſt, and, conſequently, in that place that lies to the eaſtermoſt, the noon happens ſooneſt; and the hour of the day or diſtance of the ſun from the meridian at any other time muſt be greateſt.

Whence it appears, that if, by any contrivance whatſoever, the hour of the day at the ſame point of abſolute time in two different places can be obtained, the difference of longitude between thoſe places is alſo known; and by comparing the times together, it is eaſy to pronounce which place of the two lies to the eaſtward or weſtward of the other.

Wherefore if two or more perſons can view the ſame appearance at two or more places, and pronounce the time at each place when ſuch appearance was viſible; or if the time when any notable appearance ſhall happen at any place be predicted, and the time when that appearance was viſible at any other place was determined; theſe times being compared together, will give the difference of meridians, or difference of longitude between the two places.

Now ſince an eclipſe of the moon proceeds from nothing

thing elſe but an interception of the earth between her and the ſun, by which means ſhe is prevented from reflecting the light ſhe receives from the ſun, the moment that any part of her body begins to be deprived of the ſolar rays, it is viſible to all thoſe people who can ſee her at the ſame time; whence if two or more different people, at two or more different places, obſerve the times when it firſt began or ended, or note the time when any number of digits was eclipſed, or when the ſhadow begins to cover or quit any remarkable ſpot, the difference of thoſe times, if there be any, when compared together, will give the difference of longitude between the places of obſervation.

The longitudes of places may alſo be determined from the obſervations of ſolar eclipſes; but theſe being incumbered with the conſiderations of parallaxes, are not near ſo proper as thoſe of the moon are; and each of theſe happening but rarely, another excellent expedient has been thought of, and that is the eclipſes of Jupiter's ſatellites.

Jupiter has been found to have four ſatellites or moons conſtantly attending him, always obſerving the ſame laws in moving round about him. See the article JUPITER.

Now as neither Jupiter nor any of his attendants have any native light of their own, but ſhine with a borrowed light from the ſun, it happens that each of theſe, in every revolution about Jupiter, ſuffers two eclipſes, one at their entrance into the ſhadow, the other at the entrance of their paſſage behind his body; whence in each revolution of the ſatellite there are four remarkable appearances, by the obſervation of any one of which the buſineſs may be done, viz. one at the entrance into the ſhadow, and one at the emerſion out of it; one at the entrance behind the body, and another at the coming out; but the latter of theſe, viz. the ingreſs and egreſs of the ſatellite, into and from under the body, is not ſo much regarded by aſtronomers as the immerſion into and out of the ſhadow, becauſe, in the former, the difficulty of pronouncing the exact time is very great, it requiring, in each obſerver, eyes equally good and ſtrong, and teleſcopes equally large; but the obſervation of the former of theſe, viz. the immerſion into, and emerſion out of the ſhadow, is eaſy and practicable, becauſe the quick motions of the ſatellites plunge them ſo quick into the ſhadow of Jupiter, that it is no difficult matter to pronounce, by any teleſcope, by which they may be ſeen, the exact time of their immerſion and emerſion, as any one may ſoon be ſatisfied, if he will but try the experiment.

Now, inaſmuch as each of theſe happens at the ſame moment of abſolute time, if two or more perſons, in different places, note the time of obſervation, theſe, when compared together, will give the difference of longitude between the two places of obſervation. And, when we conſider the great number of theſe eclipſes that happen every year, there being more viſible in one year than there are days in it, and, conſequently, but few nights when Jupiter may be ſeen, and which is near eleven months of the year, but that an eclipſe of one or other happens, and ſometimes two or three in a night; the eaſineſs with which they may be made, there requiring only a teleſcope of eight or ten feet in length, which may be almoſt managed with the hand; and the little likelihood there is of miſſing the times of ingreſs or egreſs, they being in a manner momentaneous; and laſtly, the great exactneſs to which they would give the difference of longitude, it being certainly as exact as the latitude can at preſent be taken; it is much to be wondered at, that the more ſkilful part of our ſeamen have ſo long neglected them, and eſpecially in the ſeveral ports into which they ſail.

Beſides theſe, there is another method equally uſeful, expeditious, and certain; and that is, the appulſes of the moon to certain fixed ſtars, and their occultations by the interpoſition of her body; for, the moon finiſhing her revolution in the ſpace of twenty-ſeven days, ſeven hours, forty-three minutes, there are but few clear nights, when the moon does not paſs over, or ſo near to ſome fixed ſtar, that her diſtance from it, or the time of her viſible conjunction with it, may be eaſily obſerved by the teleſcope and micrometer only; and theſe when compared together, or with the viſible time computed to the meridian of ſome place when a good theory of the moon ſhall be obtained, will ſhew the difference of longitude of thoſe places.

The lunar theory is already brought to very great perfection, and the Nautical Ephemerides, now preparing by that able mathematician Mr. George Witchel, will, it is hoped, render the method of finding the longitude at ſea very practicable; eſpecially as the ingenious Mr. Maſkeline has already favoured the world with a treatiſe called the Mariner's Guide, wherein he has fully explained the method of finding the longitude from obſervations made on the appulſes of the moon to the fixed ſtars.

Mr. Flamſteed has given us the places of near one thouſand fixed ſtars, confirmed by ſeveral obſervations, that lie within the zodiac, each of which will be covered by the moon and the reſt of the planets, in one revolution of their node; ſo that ſcarce one night can happen but ſome one or other of them will be eclipſed, or approached ſo near unto, as to come within the compaſs of a teleſcope, in one place of the earth or other: add to theſe the eclipſes of Jupiter's ſatellites, and it is ſcarce poſſible that any clear night can happen, but the heavens afford us ſome agreeable phænomenon or other, by which the longitude of any place may be duly aſcertained.

In the Philoſophical Tranſactions, N° 1, we have an account of a ſucceſsful experiment made with two pendulum-watches by major Holmes, in a voyage from the coaſt of Guinea homewards. This and ſome other ſucceſſes encouraged monſieur Huygens ſo far, that, after he had improved the ſtructure of theſe watches, he publiſhed an account at large for the ſhewing how and in what manner theſe watches are to be uſed in finding the longitude at ſea, with directions for adjuſting of them and keeping a journal by them; which account the curious reader may ſee at large in the Philoſophical Tranſactions, N° 47.

This method has been purſued by the ingenious Mr. John Harriſon, who, after many years labour, has at laſt completed a time-keeper, which has every requiſite neceſſary for finding the longitude at ſea; and from ſeveral experiments, particularly two voyages to the Weſt-Indies, it was found to keep time ſo very accurately as not to vary above a minute in the whole voyage: and he has accordingly received 10,000l. being half the ſtipulated reward for this diſcovery; and will, it is preſumed, receive the other moiety as ſoon as his watch ſhall be found to keep time with the ſame degree of accuracy, in the frozen zone. The reader will therefore be pleaſed with finding ſome account of this ingenious contrivance, which we ſhall give from a report delievered to the board of longitude, by Mr. William Ludlam, one of the gentlemen to whom Mr. Harriſon was referred to make a diſcovery of the principles of his time pieee.

"The defects in common watches, ſays Mr. Ludlam, which Mr. Harriſon propoſes to remedy, are the following.

"1. That the main-ſpring acts not conſtantly with the ſame force upon the wheels, and through them upon the balance. 2. That the balance, either urged with an unequal force, or meeting with a different reſiſtance from the air, or the oil, or the friction, vibrates through a greater or leſs arch. 3. That theſe unequal vibrations are not performed in equal times. 4. That the force of the balance-ſpring is altered by a change of heat.

"To remedy the firſt defect, Mr. Harriſon has contrived, that his watch ſhall be moved by a very tender ſpring, which never unrolls itſelf more than one eighth part of a turn, and acts upon the balance through one wheel only. But ſuch a ſpring cannot keep the watch in motion a long time. He has therefore joined another, whoſe office is to wind up the firſt ſpring eight times in every minute, and which is itſelf wound up but once in a day.

"To remedy the ſecond defect, Mr. Harriſon uſes a much ſtronger balance-ſpring than in a common watch. For if the force of this ſpring upon the balance remains the ſame, whilſt the force of the other varies, the errors ariſing from that variation will be the leſs as the fixed force is the greater. But a ſtronger ſpring will require either a heavier or a larger balance. A heavier balance would

would have a greater friction. Mr. Harriſon therefore increaſes the diameter of it. In a common watch it is under an inch, in this of Mr. Harriſon's two inches and two tenths.

"Had theſe remedies been perfect, it would have been unneceſſary to conſider the defects of the third ſort. But the methods already deſcribed only leſſening the errors, not removing them, Mr. Harriſon uſes two ways to make the times of the vibrations equal, though the arches may be unequal. One is to place a pin, ſo that the balance-ſpring, preſſing againſt it, has its force increaſed; but increaſed leſs when the vibrations are larger; the other to give the palates ſuch a ſhape, that the wheels preſs them with leſs advantage, when the vibrations are larger.

"To remedy the laſt defect, Mr. Harriſon uſes a bar compounded of two thin plates of braſs and ſteel, about two inches in length, rivetted in ſeveral places together, faſtened at one end, and having two pins at the other, between which the balance-ſpring paſſes. If this bar be ſtraight in temperate weather, braſs changing its length by heat more than ſteel, the braſs ſide becomes convex when it is heated; and the ſteel ſide, when it is cold: and thus the pins lay hold of a different part of the ſpring in different degrees of heat, and lengthen or ſhorten it, as the regulator does in a common watch.

"The two firſt of theſe improvements, any good workman, who ſhould be permitted to view and take to pieces Mr. Harriſon's watch, and be acquainted with the tools he uſes, and the directions he has given, could, without doubt, exactly imitate. He could alſo make the palates of the ſhape propoſed; but for the other improvements, Mr. Harriſon has given no rules. He ſays, that he adjuſted thoſe parts by repeated trials, and that he knows no other method. This ſeems to require patience and perſeverance; but with theſe qualifications other workmen need not deſpair of ſucceſs equal to Mr. Harriſon's. There is no reaſon to ſuſpect that Mr. Harriſon has concealed from us any part of his art.

"If our opinion of the excellence and uſefulneſs of this machine be aſked, I muſt fairly own, that nothing but experience can determine the uſe of it with certainty; however, I think it my duty, ſays the above gentleman, to declare to the board the beſt judgment I can form.

"The firſt of Mr. Harriſon's alterations is, I believe, an improvement, but not very conſiderable. Probably if the other defects in common watches could be removed, the changes in the force of the main-ſpring would not occaſion ſuch errors as would make them uſeleſs at ſea.

"The next alteration ſeems to be of greater importance; I ſuppoſe that it contributes more to the exactneſs of the watch, than all the other changes put together; but is attended with ſome inconvenience. The watch is liable to be diſordered, and even ſtopped by almoſt any ſudden motion, and, when ſtopped, does not move again of itſelf. But as it has gone two voyages without any ſuch accident, it may ſeem that this danger at ſea is not conſiderable.

"The principle on which Mr. Harriſon forms the alterations of the third ſort is, that the longer vibrations of a balance moved by the ſame ſpring, are performed in leſs time. This is contrary to the received opinion among the philoſophers and workmen. But if Mr. Harriſon is right, yet whether the method he has propoſed will correct the errors, or not, is to me quite uncertain.

"The laſt alteration beforementioned is ingenious and uſeful; but that it can be made to anſwer exactly to the different degrees of heat, ſeems not probable."

LONGITUDE *of Motion*, according to ſome philoſophers, is the diſtance which the center of any moving body runs through, as it moves on in a right line. See the article MOTION.

LONGITUDINAL, in general, denotes ſomething placed lengthwiſe: thus ſome of the fibres of the veſſels in the human body are placed longitudinally, others tranſverſely, or acroſs.

LONICERA, honey-ſuckle, in botany, a genus of plants, the corolla of which conſiſts of a ſingle petal; the tube is oblong and gibboſe downwards; the limb is divided into five ſegments, one of which is more deeply ſerrated than the reſt: the fruit is a roundiſh umbilicated berry, containing two cells; the ſeeds are roundiſh and compreſſed.

LOOF, in ſhip-building, that part of a ſhip where the bow begins, or where the planks of her fore part begin to bend, and round inward, as ſhe grows narrower approaching the ſtem. See BOW.

LOOKING-GLASSES are nothing but plane mirrors of glaſs; which being impervious to the light, reflect the images of things placed before them; for the theory of which ſee the articles MIRROR and REFLECTION.

For the caſting, grinding, and poliſhing glaſſes, ſee the article GLASS.

For foliating of looking-glaſſes, ſee the article FOLIATING.

LOOM, a frame compoſed of a variety of parts, uſed in all the branches of weaving; for a particular deſcription of which, ſee WEAVING.

LOOMING, in the ſea-language, appearance, as the ſhip looms large, i. e. appears towering.

LOOP, in the iron works, denotes a part of a ſow, or block of caſt iron, broken or melted off from the reſt.

LOPPING, among gardeners, the cutting off the ſide branches of trees.

It is very obſervable that moſt old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of thoſe who have the management of them, who ſuffer the tops to grow large before they lop them; as the aſh, elm, hornbeam, &c. and perſuade themſelves, that they may have the more great wood; but, in the mean time, do not conſider that the cutting off great tops endangers the life of a tree; or, at beſt, wounds it ſo, that many trees yearly decay more in their bodies, than the yearly tops come to; and at the ſame time that they furniſh themſelves with more great wood, they do it at the loſs of the owner. And, indeed, though the hornbeam and elm will bear great tops, when the body is little more than a ſhell; yet, the aſh, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays. Therefore, if once theſe trees decay much in the middle, they will be worth little but for the fire; ſo that if you find a timber-tree decay, it ſhould be cut down in time that the timber be not loſt.

The lopping of your trees, that is, at ten or twelve years old at moſt, will preſerve them much longer, and will occaſion the ſhoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, ſpoil many a tree; for which reaſon they ſhould always be taken off cloſe and ſmooth, and not parallel to the horizon; and cover the wound with loam and horſe-dung mixed, to prevent the wet from entering the body of the tree.

When trees are at their full growth, there are ſeveral ſigns of their decay; as the withering or dying of many of their top branches; or if the wet enters at any knot; or they are anywiſe hollow, or diſcoloured; if they make but poor ſhoots; or if woodpeckers make any hole in them.

This lopping of trees is only to be underſtood for pollard-trees; becauſe nothing is more injurious to the growth of timber-trees, than that of lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and ſize, growing near each other, to lop or cut off the ſide branches from one of them, and ſuffer all the branches to grow upon the other, will in a few years, find the latter to exceed the other in growth every way; and this will not decay near ſo ſoon.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped very ſparingly; for they are ſubject to decay, when often cut. The beſt ſeaſon for lopping theſe trees is ſoon after Bartholomew tide; at which time they ſeldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Dict.*

The lopping of young trees, that is, of ſuch as are ten or twelve years old, will preſerve them much longer, and will occaſion the ſhoots to grow more into wood in one year, than they do in old tops in two or three. The taking off of large boughs in a careleſs manner deſtroys many a tree; they ſhould therefore always be lopped with great

great care, and the wound covered with ſome loam to keep it from rotting, and prevent the wet from entering and getting into the body of the trees.

All ſorts of reſinous trees, or ſuch as abound with a milky juice, ſhould be lopped but very ſparingly, for they are very ſubject to decay, when cut. The beſt ſeaſon for the lopping theſe is the end of Auguſt, when they will not bleed very much, and the wounds will heal before the hard weather.

The generality of the world are againſt pruning timber trees at all, and, where they naturally grow ſtraight and regular, it is much better let alone. But all common faults in ſhape may be regulated by this lopping them while young, and it can be attended with no ill conſequence to the timber; for the cut not lying near the timber pith cannot affect it, when grown up, and ſquared in the working for beams and other uſes, or to be quartered; for all the defects occaſioned by ſuch wounds, are in the ſuperficial parts, and all the four quarters are perfectly ſound within.

As to the large foreſt trees, they ſhould not be lopped at all, except in caſes of great neceſſity, and then the large boughs muſt not be cut, but only the ſide branches; and even theſe muſt be cut off cloſe, that the bark may ſoon cover the wound, and yet a little ſlanting, that the water may run off, not lodge upon the cut part.

If there is a neceſſity of cutting off a large bough, as by its being broken or cankered, let it be cut off ſlanting at about four feet diſtance from the body of the tree, and that if poſſible near ſome place where there is a young ſhoot from it, which may receive the ſap, and grow up in its place. No ſtump muſt be left ſtanding out farther than this, becauſe they are wounded parts which never can heal, and which will always be letting in the water, and will ſerve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly ſpoil it. All that grow upright, whether they be large or ſmall branches, muſt in cutting be taken off ſlanting, never evenly, for the ſame reaſon; thoſe boughs that bear from the head are to be cut with the ſlope on the lower ſide, and on any occaſion that great wounds are given to a tree, they ſhould be covered with a mixture of clay and horſe-dung, which will make them heal much ſooner than they otherwiſe would do. *Mortimer's Huſbandry.*

LORD, a title of honour, given to thoſe who are noble, either by birth or creation; in this ſenſe it amounts to much the ſame as peer of the realm, or lord of parliament. This title, by the courteſy of England, is alſo given to all the ſons of dukes and marquiſes, and to the eldeſt ſons of earls: and it is alſo a title of honour beſtowed on thoſe who are honourable by their employments, as lord advocate, lord chamberlain, lord chancellor, &c.

LORICATION, COATING, in chemiſtry, is the covering a glaſs or earthen veſſel with a coat or cruſt of a matter able to reſiſt the heat, to prevent its breaking in the performing an operation that requires great violence of fire.

When veſſels are expoſed naked to the greateſt fire, it eaſily happens that they burſt by throwing freſh cold fuel into the fire, for the preventing of which, the operator muſt have recourſe to lorication, or coating. This is performed in the following manner: Take ſome of the ſame matter of which the muffles and crucibles are made, and inſtead of water moiſten it with freſh blood not yet coagulated, and diluted with twice or thrice the ſame quantity of water, to make a thin paſte of it; then add to this paſte cow's hairs, or other hairs, not very long nor ſtiff, and if you have at hand glaſs pulverized and ſifted, it may alſo be of ſervice to mix ſome of it with the reſt; then with this maſs beſmear your veſſel with a pencil, and dry it; when dried, beſmear it a ſecond time, and dry it again; repeat this a third and fourth time, till the veſſel be covered over with a cruſt or coat, one third or fourth part of an inch. See CRUCIBLE.

LOTION, *Lotio*, waſhing, in phyſic, a ſort of medicine compounded of liquid ingredients for beautifying the face, and cleanſing it from any deformity which the blood throws out. It alſo denotes a medicine that holds a medium between a fomentation and a bath.

LOTION, in pharmacy, a preparation of medicines by waſhing in ſome liquid, either to clear them of the dregs, or of ſome ſalt or corroſive ſpirit, or to communicate ſome virtue to them.

LOTUS, the ſquare podded vetch, in botany, a genus of plants, the corolla of which is papilionaceous; the vexillum is roundiſh, and bent back, with an oblong concave unguis; the alæ are roundiſh, and ſhorter than the vexillum; the carina is gibbous underneath, and ſhut above: the fruit is a cylindric pod, conſiſting of two valves, and containing two cells: the ſeeds are numerous and roundiſh.

LOVAGE, in botany, the Engliſh name for the liguſticum. See LIGUSTICUM.

LOVE-APPLE, the fruit of a ſpecies of ſolanum, a plant cultivated in gardens among us for the ſingularity of its appearance; the Portugueſe eat this fruit either raw or ſtewed, as do alſo the Jew-families in England.

LOUIS, *or Knight of* St. LOUIS, the name of a military order in France inſtituted by Louis XIV. in 1693. Their collars are of a flame-colour, and paſs from left to right; the king is their grand maſter.

LOUSE, *Pediculus*, in zoology. See the article PEDICULUS.

LOWERING, among diſtillers, a term uſed to expreſs the debaſing the ſtrength of any ſpirituous liquor by mixing water with it. The ſtandard and marketable price of theſe liquors is fixed, in regard to a certain ſtrength in them called proof; this is that ſtrength, which makes them, when ſhook in a phial, or poured from on high into a glaſs, retain a froth or crown of bubles for ſome time. In this ſtate ſpirits conſiſt of about half pure, or totally inflammable ſpirits, and half water; and if any foreign or home ſpirit is to be expoſed to ſale, and is found to have that proof wanting, ſcarce any one will buy it, till it has been diſtilled again, and brought to that ſtrength; and if it be above that ſtrength, the proprietor uſually adds water to it, to bring it down to that ſtandard. This addition of water, to debaſe its ſtrength, is what is called lowering it. People well acquainted with the goods will indeed buy ſpirits at any ſtrength, only lowering a ſample to the proof ſtrength, and by that judging of the ſtrength of the whole; but the generality of buyers will not enter into this, but muſt have it all lowered for them.

There is another kind of lowering in practice among the retailers of ſpirituous liquors to the vulgar; this is the reducing it under the ſtandard of proof. They buy it proof, and afterwards increaſe their profit upon it, by lowering it with water one eighth part. The quantity of ſpirit is what they generally allow themſelves for the addition of water; and whoever has the art of doing this, without deſtroying the bubble proof, as this is eaſily done by means of ſome addition, that gives a greater tenacity to the parts of the ſpirit, will deceive all that judge by this proof alone; that is, very nearly all who are concerned in the ſpirit trade. Such an additional quantity of water, as one eighth, makes the ſpirit taſte ſofter and cooler, and will make many prefer it to the ſtronger ſpirit, which is hotter and more fiery; but unleſs the ſpirit, thus lowered, were tolerably clean, or the proof be ſome other way preſerved, the addition of the water lets looſe ſome of the coarſe oil, which makes the liquor milky, and leaves a very nauſeous taſte in the mouth. *Shaw's Eſſay on Diſtillery.*

LOXIA, in the Linnæan ſyſtem of zoology, the name of a genus of birds of the order of the paſſeres, the diſtinguiſhing characters of which are, that the tongue is plain, equal, and whole; the beak large, thick, and ſhort, and crooked and convex both ways.

LOZENGE, LOZANGE, *Rhombus*, in geometry, a quadrilateral figure, conſiſting of four equal and parallel ſides, two of whoſe oppoſite angles are acute, and the other two obtuſe; the diſtance between the two obtuſe ones being always equal to the length of one ſide: when the ſides are unequal, this figure is called a rhomboides.

Scaliger derives the word from the Latin *laurengia*, as this figure ſomewhat reſembles that of a laurel leaf.

LOZENGE, in heraldry, a rhombus, or figure of equal ſides, but unequal angles, reſembling a quarry of glaſs in our old windows, placed erect, pointwiſe. It is in this

figure that all unmarried gentlewomen and widows bear their coats of arms; becauſe, as ſome ſay, it was the figure of the Amazonian ſhield; or as others, becauſe it is the ancient figure of the ſpindle.

LOZENGE, in pharmacy, the ſame with what is otherwiſe called troche. See the article TROCHE.

LUCERNE, in botany, &c. a plant frequently cultivated in the manner of clover, and known among authors by the names of the medica and medicago.

It is the alfaſa of the Spaniards, and the lucerne, grand treffle, or fænum Burgundiacum, as ſome botaniſts call it, of the French. It has a perennial root, and an annual ſtalk, which riſes full three feet high in good land, and is garniſhed at each point with trifoliate leaves, whoſe lobes are ſpear-ſhaped, about an inch and a half long, and half an inch broad, ſawed towards the ſtalks. The flowers grow in ſpikes, which are from two to near three inches in length, ſtanding upon naked foot ſtalks two inches long, riſing from the wings of the ſtalks: they are of the pea bloom, or butterfly, kind; of a fine purple colour, and are ſucceeded by compreſſed moon-ſhaped pods, which contain ſeveral kidney-ſhaped ſeeds. It flowers in June, and its ſeed ripens in September.

There are the following varieties of this ſpecies of lucerne, viz. one with violet-coloured flowers: another with yellow flowers; a third with yellow and violet flowers mixed; and a fourth with variegated flowers: but, as Mr. Miller obſerves, theſe are only variations of the ſame plant, ariſing accidentally from the ſeed. However, neither the yellow, nor the variegated, flowered lucerne is ever ſo ſtrong as that with purple flowers, nor is it, conſequently, ſo profitable to the huſbandman.

Columella calls this the choiceſt of all fodder, becauſe it will laſt ten years, and will bear being cut down four, and ſometimes ſix times in a year; it enriches the land on which it grows, fattens the cattle fed with it, and is a remedy for ſick cattle. About three quarters of an acre of it is abundantly ſufficient to feed three horſes during the whole year. Yet notwithſtanding it was ſo much eſteemed by the ancients, and hath been cultivated to great advantage in France and Switzerland for many years, it has not yet found ſo good a reception in England as it juſtly deſerves; nor is it cultivated here in any conſiderable quantity, though it will ſucceed as well in this country as in either of the laſt mentioned; being extremely hardy, and reſiſting the ſevereſt cold of our climate.

The ſoil in which this plant is found to ſucceed beſt in this country, is a light, dry, looſe, ſandy land, which ſhould be well ploughed and dreſſed, and the roots of all noxious weeds, ſuch as couch graſs, &c. deſtroyed; otherwiſe theſe will over-grow the plants while young, and prevent their progreſs.

The beſt time to ſow the ſeed is about the middle of April, when the weather is ſettled and fair: for if you ſow it when the ground is very wet, or in a rainy ſeaſon, the ſeeds will burſt and come to nothing, as is often the caſe with ſeveral of the leguminous plants; therefore you ſhould always obſerve to ſow it in a dry ſeaſon, and if there happens ſome rain in about a week or ten days after it is ſown, the plants will ſoon appear above ground.

After having well ploughed and harrowed the land very fine, you ſhould make a drill quite acroſs the ground, almoſt half an inch deep, into which the ſeeds ſhould be ſcattered very thin: then cover them over a quarter of an inch thick, or ſomewhat more, with the earth: then proceed to make another drill, about a foot and a half from the former, ſowing the ſeeds therein in the ſame manner as before, and ſo proceed through the whole ſpot of ground, allowing the ſame diſtance between row and row, and ſcatter the ſeeds very thin in the drills. In this manner, an acre of land will require about ſix pounds of ſeed: for when it is ſown thicker, if the ſeeds grow well, the plants will be ſo cloſe as to ſpoil each other in a year or two, the heads of them growing to a conſiderable ſize, as will alſo the roots, provided they have room; for the crown of ſome will meaſure eighteen inches diameter; from which near four hundred ſhoots have been cut at one time, which is an extraordinary increaſe, and this upon a poor dry gravelly ſoil, which had not been dunged for many years; but the roots were at leaſt ten years old; ſo that if this crop be well cultivated, it will continue many years, and be equally good as when it was firſt ſown: for the roots generally run down very deep in the ground, provided the ſoil be dry; and although they ſhould meet a hard gravel a foot below the ſurface, yet their roots would penetrate it and make their way downward, ſome of them having been taken up, which were above a yard in length, and had run two feet into a rock of gravel, ſo hard as not to be looſened without mattocks, and crows of iron, and that with much difficulty.

The reaſon for directing this ſeed to be ſown in rows is, that the plants may have room to grow; and for the better ſtirring the ground between them, to deſtroy the weeds, and encourage the growth of the plants, which may be very eaſily effected with a Dutch hoe, juſt after the cutting the crop each time, which will cauſe the plants to ſhoot again in a very little time, and be much ſtronger than in ſuch places where the ground cannot be ſtirred: but when the plants firſt come up, the ground between ſhould be hoed with a common hoe; and if in doing of this you cut up the plants where they are too thick, it will cauſe the remaining to be much ſtronger. This hoeing ſhould be repeated two or three times while the plants are young, according as the weeds are produced, obſerving always to do it in dry weather, that the weeds may the better be deſtroyed; for if it be done in moiſt weather, they will root and grow again.

With this management, the plants will grow to the height of two feet, or more, by the beginning of Auguſt, when the flowers will begin to appear, at which time the lucerne ſhould be cut, obſerving to do it in a dry ſeaſon, if it is to be made hay, and keep it often turned, that it may ſoon dry, and be carried off the ground; for if it lie long upon the roots, it will prevent their ſhooting again. After the crop is taken off, you ſhould ſtir the ground between the rows with a hoe, to kill the weeds, and looſen the ſurface, which will cauſe the plants to ſhoot out again in a ſhort time, ſo that by the beginning of September there will be ſhoots four or five inches high, when you may turn in ſheep upon it to feed it down: nor ſhould the ſhoots be ſuffered to remain upon the plants, which would decay when the froſty weather comes on, and fall down upon the crown of the roots, and prevent their ſhooting early the ſucceeding ſpring.

The beſt way therefore is to feed it until November, when it will have done ſhooting for that ſeaſon: but it ſhould not be fed by large cattle the firſt year, becauſe the roots being young, would be in danger of being deſtroyed, either by their trampling upon them, or their pulling them out of the ground: but ſheep will be of ſervice to the roots by dunging the ground, provided they do not eat it too cloſe, ſo as to endanger the crown of the roots.

In the beginning of February, the ground between the rows ſhould be again ſtirred with the hoe, to encourage them to ſhoot again: but in doing this you ſhould be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to puſh. With this management, if the ſoil be warm, by the middle of March the ſhoots will be five or ſix inches high, when, if you are in want of fodder, you may feed it down till a week in April; after which it ſhould be ſuffered to grow for a crop, which will be fit to cut the beginning of June, when you ſhould obſerve to get it off the ground as ſoon as poſſible, and ſtir the ground again with the Dutch hoe, which will forward the plants ſhooting again; ſo that by the middle, or latter end of July, there will be another crop fit to cut, which muſt be managed as before; after which it ſhould be fed down again in autumn: and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you ſhould turn in larger cattle; but you muſt always obſerve not to ſuffer them to remain after the roots have done ſhooting, leſt they ſhould eat down the crown of the roots below the buds, which would conſiderably damage, if not deſtroy them.

In this manner you may continue conſtantly to have two crops to cut, and two feedings upon this plant; and in good ſeaſons there may be three crops cut, and two

feedings, which will be a great improvement, eſpecially as this plant will grow upon dry barren ſoils, where graſs will come to little, and be of great uſe in dry ſummers, when graſs is often burnt up: and as it is an early plant in the ſpring, ſo it will be of great ſervice when fodder falls ſhort at that ſeaſon, when it will be fit to feed at leaſt a month before graſs or clover; for this plant is often eight inches high by the middle of March, at which time the graſs in the ſame place is ſcarcely one inch high.

Cold will not injure this plant; for in the very cold winter, 1728-9, ſome roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, were again planted, and they ſhot out very vigorouſly ſoon after: nay, even while they lay upon the ground, they ſtruck out fibres from the under ſide of the roots, and had begun to ſhoot green from the crown of the roots: but wet will altogether deſtroy the roots; for a little of the ſeed being ſown upon a moiſt ſpot of ground for a trial, it came up very well, and flouriſhed exceedingly during the ſummer ſeaſon; but in winter, when the great rains fell, the roots began to rot at bottom; and before the ſpring moſt of them were deſtroyed.

The beſt places to procure the ſeed from, are Swiſſerland and the northern parts of France, which ſucceeds better with us than that which comes from a more ſouthern climate: but this ſeed may be ſaved in England in great plenty; in order to which, a ſmall quantity of the plants ſhould be ſuffered to grow uncut till the ſeeds are ripe, when it muſt be cut, and laid to dry in an open barn, where the air may freely paſs through: but the ſeed muſt be defended from the wet; for if it be expoſed thereto, it will ſhoot while it remains in the pod, whereby it will be ſpoiled. When it is quite dry, it muſt be threſhed out, and cleanſed from the huſk, and preſerved in a dry place till the ſeaſon for ſowing it: and this ſeed ſaved in England is much preferable to any brought from abroad; the plants produced from it being much ſtronger than thoſe produced from the French, Helvetian, and Turky ſeeds, which are ſown at the ſame time, and on the ſame ſoil and ſituation.

LUCID INTERVALS, in lunatics, the times wherein they appear to be in their ſenſes. See the article LUNATIC.

LUCINDA, in aſtronomy, an appellation given to ſeveral fixed ſtars on account of their ſuperior brightneſs; as the lucida coronæ, a ſtar of the ſecond magnitude, in the northern crown; the lucida hydræ, or cor hydræ; and the lucida lyræ, a ſtar of the firſt magnitude in that conſtellation.

LUCIUS, the pike, or jack, in ichthyology, a ſpecies of eſox, with a depreſſed roſtrum.

The pike grows to a conſiderable ſize, but uſually is found from fourteen inches to two feet in length: it is all over variegated with round yellowiſh ſpots. It is a well known and very voracious fiſh.

LUES, among phyſicians, is, in general, uſed for a diſeaſe of any kind; but, in a more particular ſenſe, is reſtrained to contagious and peſtilential diſeaſes: thus the lues Gallica, or venerea, ſignifies the venereal diſeaſe.

LUFF, amongſt ſailors, the order from the pilot to guide the ſhip's head nearer to the direction of the wind, or nearer to that part of the horizon from which the wind bloweth.

She keeps a good LUFF, i. e. holds her way well, without deviating to the leeward of her courſe. See the article LEEWARD.

LUFF-TACKLE, a complication of pullies conſiſting of two blocks, which may be either both of them double, or one of them ſingle. The rope which forms the tackle, and is called the fall, is paſſed alternately through the blocks, and then has its end faſtened to one of them, till it becomes four or five fold: the mechanical power of a luff-tackle is very great, inſomuch that three or four men will draw as much weight with this as ſeven or eight would with a ſingle rope faſtened to the ſame body. See the article TACKLE.

This experiment might undoubtedly be aſcertained with the niceſt accuracy, but we do not remember to have heard or read of its being done: it might, however, be worth the trial of ſome curious mechanic.

LUKE, or *Goſpel of St.* LUKE, a canonical book of the New Teſtament.

Some think it was properly St. Paul's Goſpel, and that when that Apoſtle ſpeaks of his Goſpel, he means what is called St. Luke's. Irenæus ſays, that St. Luke digeſted into writing what St. Paul preached to the Gentiles; and Gregory Nazianzen tells us, that St. Luke wrote with the aſſiſtance of St. Paul.

"St. Luke, ſays a modern writer, is pure, copious, and flowing in his language, and has a wonderful and entertaining variety of ſelect circumſtances in his narration of our Saviour's divine actions. He acquaints us with numerous paſſages of the Evangelical hiſtory, not related by any other Evangeliſt; both in his Goſpel and Apoſtolical Acts, he is accurate and neat, clear and flowing, with a natural and eaſy grace: his ſtyle is admirably accommodated to the deſign of his hiſtory; it had a good deal of reſemblance to that of his great maſter St. Paul; and, like him, he had a learned and liberal education. I believe he had been very converſant with the beſt claſſics; for many of his words and expreſſions are exactly parallel to theirs." *Blackwall's Sacred Claſſics.*

St. LUKE *the Evangeliſt's Day*, a feſtival in the Chriſtian church, obſerved on the eighteenth of October.

LUMBAGO, in phyſic, a violent pain in the loins, which affects the patient in ſuch a manner that he can ſcarcely move. It is a ſcorbutic ſymptom, and frequently excited by the gout or rheumatiſm.

LUMBARIS, a name given to the arteries and veins which ſpread over the loins; or an epithet to diſtinguiſh thoſe branches of the aorta which carry the blood to the muſcles of the loins, to thoſe of the abdomen and other of the circumjacent parts, and alſo to certain veins which bring back the blood from the loins into the trunk of the vena cava.

LUMBRICAL, a name given to four muſcles of the fingers, and to as many of the toes. They are in each called the flexors of the firſt phalanx; thoſe of the fingers ariſe deep and tendinous, and are inſerted into the firſt phalanges on the ſide next the thumb: thoſe of the toes have their origin from the tendon of the muſculus perforans, and from the interior part of the calcaneum: their termination is at the firſt phalanx of the ſeveral toes.

LUNA, in aſtronomy, the moon. See the article MOON.

LUNA, among chemiſts, ſignifies ſilver. See SILVER.

LUNAR, ſomething belonging to the moon; thus we ſay lunar month, lunar year, lunar dial, lunar eclipſe, &c. See the articles MOON, MONTH, YEAR, &c.

LUNATIC, a perſon affected with lunacy, the cure of which is to be attempted by evacuations of all kinds; as bleeding, vomiting, cathartics, &c. See MADNESS.

LUNGS, a part of the human body, which is the cauſe or inſtrument of reſpiration. The lungs are the largeſt viſcus of the thorax: they are ſituated in the two ſides of it, with the heart as it were between them; and are connected, by means of the mediaſtinum, with the ſternum and vertebræ; with the heart, by means of the pulmonary veſſels, and immediately with the aſpera arteria. The colour of the lungs, in infants, is a fine florid red; in adults, it is darker; and in old people, livid, or variegated with black and white. When inflated, they have ſome reſemblance to the hoof of an ox; and are convex on the upper ſide, and concave underneath. They are divided into two large lobes, the right and left; the left, which is the ſmaller, is divided again into three ſmaller ones. The membrane with which the lungs are ſurrounded, is continuous with the pleura. The ſubſtance of the lungs is ſpongeous, or veſiculous, and they ſeem, indeed, entirely compoſed of a number of ſmall veſicles of a fleſhy texture, and of a variety of veſſels.

The veſſels of the lungs are the bronchia, the bronchial artery and vein, the pulmonary artery and vein, the nerves, and the lymphatics. See BRONCHIA, &c.

The uſes of the lungs are, 1. To perform the office of reſpiration, by which the blood is attenuated in the plexus of the arteries called the rete vaſculoſum. 2. To be aſſiſtant to the voice in ſpeaking, and to the ſenſe of

ſmelling. They are alſo emunctories of the blood, and are of many other important ſervices.

LUNG-WORT, *Pulmonaria*, in botany. See PULMONARIA.

LUNISOLAR YEAR, in chronology, a period of years produced by multiplying the cycle of the moon, 19, by 28, that of the ſun; the product is 532; in which ſpace of time theſe luminaries return to the ſame point in the heavens.

LUNULA, in geometry, a plane figure like a creſcent, or half-moon, for the quadrature of which, ſee QUADRATURE.

LUPERCALIA, in antiquity, a feſtival of the antient Romans in honour of the god Pan, obſerved on the fifteenth of February, and ſo called from the luperci, the prieſts of that fabulous deity.

LUPIA, in ſurgery, a kind of encyſted tumor, called alſo talpa and teſtuda. See ENCYSTED and TUMOR.

LUPINE, *lupinus*, in botany, a genus of plants, the corolla of which is papilionaceous; the vexillum is cordated, roundiſh, and emarginated: the alæ are oval, and almoſt of the ſame length with the vexillum; the carina is divided into two ſegments at the baſe: the fruit is a large, oblong, coriaceous, compreſſed, acuminated pod, containing only one cell: the ſeeds are numerous, roundiſh, and compreſſed.

LUPULMUM, in botany, a ſpecies of trefoil. See the article TREFOIL.

LUPULUS, the hop, in botany, &c. See the article HOP.

LUPUS, the wolf, in zoology. See the article WOLF.

LUPUS MARINUS, the ſea-wolf, in ichthyology, conſtitutes a diſtinct genus of malacopterygious fiſhes; with a compreſſed body, and ſix or more oſſicles in the membrane of the gills. On the back there is only one fin, which extends almoſt from the head to the tail. It is a very ſingular fiſh, growing to four or five feet long.

LUPUS, in aſtronomy, a conſtellation of the ſouthern hemiſphere. See CENTAUR.

LURE, in falconry, a device of leather, in the form of a bird, with two wings ſtuck with feathers, and baited with a piece of fleſh; wherewith to reclaim or call back a hawk, when at a conſiderable diſtance.

LUSERNE, or LUCERNE. See LUCERNE.

LUSTRATION, in antiquity, ſacrifices or ceremonies by which the antients purified their cities, fields, armies, or people, defiled by any crime or impurity. Some of theſe luſtrations were public, others private. There were three ſpecies or manners of performing luſtrations, viz. by fire and ſulphur, by water, and by air, which laſt was done by fanning and agitating the air round the thing to be purified. Some of theſe luſtrations were neceſſary, that is, could not be diſpenſed with, as luſtrations of houſes in time of a plague, or upon the death of any perſon: others again were done out of choice, and at pleaſure. The public luſtrations at Rome were celebrated every fifth year, in which they led a victim thrice round the place to be purified, and in the mean time burnt a great quantity of perfumes. Their country luſtrations, which they called ambarvalia, were celebrated before they began to reap their corn: in thoſe of the armies, which they called armiluſtria, ſome choſen ſoldiers, crowned with laurel, led the victims, which were a cow, a ſheep, and a bull, thrice round the army ranged in battle-array in the field of Mars, to which deity the victims were afterwards ſacrificed, after pouring out many imprecations on the enemies of the Romans. The luſtrations of their flocks were performed in this manner: the ſhepherd ſprinkled them with pure water, and thrice ſurrounded his ſheepfold with a compoſition of ſavin, laurel, and brimſtone ſet on fire, and afterwards ſacrificed to the goddeſs Pales an offering of milk boiled, wine, a cake and millet. As for private houſes, they were luſtrated with water, a fumigation of laurel, juniper, olive-tree, ſavin, and ſuch like; and the victim commonly was a pig. Luſtrations made for particular perſons were commonly called expiations, and the victims piacula. There were alſo a kind of luſtration uſed for infants, by which they were purified, girls the third, and boys the ninth day after their birth, which ceremony was performed with pure water and ſpittle.

LUSTRE, the gloſs or brightneſs appearing on any thing, particularly on manufactures of ſilk, wool, or ſtuff. It is likewiſe uſed to denote the compoſition or manner of giving that gloſs.

The luſtre of ſilks is given them by waſhing in ſoap, then clear water, and dipping them in alum-water cold. To give ſtuffs a beautiful luſtre, for every eight pounds of ſtuff allow a quarter of a pound of linſeed; boil it half an hour, and then ſtrain it through a cloth, and let it ſtand till it is turned almoſt to a jelly: afterwards put an ounce and a half of gum to diſſolve twenty-four hours; then mix the liquor, and put the cloth into this mixture; take it out, dry it in the ſhade, and preſs it. If once doing is not ſufficient, repeat the operation. Curriers give a luſtre to black leather firſt with juice of bar-berries, then with gum-arabic, ale, vinegar, and Flanders glue, boiled together. For coloured leather, they uſe the white of an egg beaten in water. Moroccoes have their luſtre from juice of bar-berries and lemon or orange. For hats, the luſtre is frequently given with common water, ſometimes a little black dye is added: the ſame luſtre ſerves for furs, except that for very black furs they ſometimes prepare a luſtre of galls, copperas, Roman alum, ox's marrow, and other ingredients.

LUSTRUM, in Roman antiquity, a general muſter and review of all the citizens and their goods, which was performed by the cenſors every fifth year, who afterwards made a ſolemn luſtration.

LUTE, or LUTING, among chemiſts, a mixed, tenacious, ductile ſubſtance, which grows ſolid with drying; and when applied to the junctures of veſſels for diſtillation, ſtops them up.

When the ſubject is merely aqueous, linſeed meal, ground fine, and well worked up into a ſtiff paſte with the white of an egg, makes a proper luting; it grows hard with heat, and if it happens to crack, it is repaired by a freſh application.

In the diſtillation of all fermented inflammable ſpirits and volatile alcaline ſalts, a paſte made of the ſame meal, well worked up with cold water, anſwers very well.

In the diſtillation of mild acids or acetous liquors, a bladder ſteeped in water, till it grows ſlimy, makes an excellent luting.

A luting that acquires a ſtony hardneſs is neceſſary in the diſtillation of foſſil acids, as vitriol, ſea-ſalt, &c. which is called the philoſophical luting, and may be prepared from the calx of copperas and quick lime, by boiling the caput mortuum in vitriol, in ſeveral parcels of water, till thoroughly waſhed, then drying the powder and preſerving it in a cloſe veſſel. This powder is to be rubbed with an equal quantity of quick-lime, and wrought into a paſte with the whites of eggs firſt beat thin; and this luting is immediately to be applied to the veſſel, being firſt a little heated: or beat pure ſand and potter's clay together in ſuch proportion with water, till the matter no longer ſticks to the fingers; then add a fourth part of common lime, and the drier this is applied, the better, provided it be left ductile, and the cracks are eaſily ſtopped up by the ſame.

To coat veſſels in the ſtronger diſtillations with a naked fire, beat fat potters earth and powdered ſand with water into a well wrought paſte, which will not ſtick to the fingers, adding a little common lime at the laſt, and beating them together: then, the veſſel being expoſed to the vapour of hot water, ſpread the cement all over it equably with the hand, afterwards ſprinkle the ſurface of the coating with hot and dry ſand, and let the coat dry ſlowly in a cool place, minding to fill up the cracks.

The London chemiſts uſe for the ſame purpoſe ſifted wood aſhes beat up to a due conſiſtence with the white of eggs and a little gum water. The ſame ſervice may be performed in a more excellent manner by a mixture of linſeed oil and ceruſs made by inſolation or decoction, and afterwards ground upon a marble with freſh ceruſs, till the whole be of the conſiſtence of an unguent.

LUTE is alſo a muſical inſtrument with ſtrings.

LUTHERANS, the Chriſtians who follow the opinions of Martin Luther, one of the principal reformers of the church in the ſixteenth century.

LUTHERN, in architecture, a kind of window over the corniche, in the roof of a building; ſtanding perpendicularly

cularly over the naked of a wall, and ſerving to illuminate the upper ſtory.

Lutherns are of various forms, as ſquare, ſemi-circular, round, called bulls-eyes, flat arches, &c.

LUTRA, the otter, in zoology. See the article OTTER.

LUTUM, among chemiſts, denotes a lute; and *lutum ſapientiæ*, the hermetical ſeal. See LUTE and HERMETICAL.

LUXATION, *Luxatio*, in ſurgery, the receſs or removal of the moveable extremity of a bone from the hollow or ſocket in which it naturally moved, accompanied with a hindrance of motion. This removal is either total or partial; the former is a luxation, and the latter a diſtortion.

The method of healing luxations is very near the ſame with that of fractures.

To cure a luxation two things are neceſſary; firſt, a reduction of the luxated parts; and ſecondly, a retention of them in their natural ſituation.

We are alſo, during the courſe of the cure, by proper remedies and a due regimen, to mitigate the moſt troubleſome ſymptoms, and to prevent future ones.

The retaining diſlocated bones in their proper ſituation, may be compaſſed with leſs difficulty than in fractured bones; for luxations in the upper extremities ſeldom require any ſtrict bandage, or long reſt. But when this happens in the lower extremities, the patient ſhould reſt ſome days in his bed, and not move the limb, till the joint has recovered its uſual ſtrength.

In a luxation of long ſtanding likewiſe a bandage and reſt are altogether neceſſary, till the former vigour of the ligaments is reſtored; though here, without a gentle motion, there will be danger of a ſtiffneſs. In the mean time it will be proper to bathe the bandages plentifully with ſome warm ſtrengthening ſpirit. The bandages ſhould be neither too tight, nor too lax. The application of plaſters, mean time, is rather pernicious than ſerviceable.

The treatment of the ſymptoms attending diſlocations, as inflammations, tumors, pains, convulſions, and hæmorrhages, is the ſame as that in fractures and wounds; but after reduction they generally diſappear inſenſibly. When the ligaments are very much debilitated, it is extremely ſerviceable, after having rubbed the part well with warm linen, to foment it with burnt rectified ſpirit of wine, and after that a quantity of ſome ſtrengthening ſpirit, as directed in fractures, applying a proper bandage.

If a luxation is attended with a wound, the eighteen-headed bandage is proper. An abſceſs ſhould be opened, as ſoon as it is ripe; for otherwiſe the pus will corrode the articulation or bone, and produce a dangerous fiſtula, which can be remedied only by amputation. When the adjacent ligament, tendons, and ſkin, are broken and deſtroyed, the caſe is then, according to Hippocrates, abſolutely incurable; and they will be ſo far from uniting firmly, that an attempt to reduce them will excite convulſions and a gangrene: for the preſervation of life, therefore, the limb ſhould be immediately amputated.

LYCANTHROPY, *Lycanthropia*, in phyſic, a ſpecies of madneſs or melancholy, in which the patients wander about in the night-time, and in every thing imitating the wolves. Some bite and ſnarl like dogs, and hence it has been called cynanthropy.

The word is derived from the Greek, λυκος, a wolf, and ανθρωπος, a man.

In the time of the fit the patient ſhould be treated with phlebotomy, the blood being ſuffered to run till he faints. Meats of good juice, with baths of ſweet water, are to be preſcribed. Whey is to be drank for three days together, and a purge of hiera or colocynthis twice or thrice adminiſtered. After purging, theriaca is to be exhibited, together with other things proper for the cure of melancholy. *Oribaſius.*

LYCEUM, in Grecian antiquity, an academy ſituated upon the banks of the Iliſſus at Athens. It was compoſed of porticos and walks, where Ariſtotle taught philoſophy; walking there conſtantly every day till the hour of anointing, whence he and his followers were called Peripatetics. See PERIPATETICS.

LYCHNIS, catch-fly, or cuckow-flower, in botany, a genus of plants, the flower of which conſiſts of five petals; the ungues of which equal the cup in length; and their limb is plain; the nectarium is compoſed of two denticles, placed in the neck of each petal: the fruit is a capſule, approaching to an oval figure, covered, and containing only one cell, with numerous roundiſh ſeeds.

LYCIUM, Avignon thorn, in botany, a genus of plants, the corolla of which is a ſingle, funnel-like petal, with a cylindraceous tube, and the limb divided into five ſegments: the fruit is a roundiſh biocular berry, containing a great many kidney-ſhaped ſeeds.

LYCODONTES, in natural hiſtory, the petrified teeth of the lupus-piſcis, or wolf-fiſh, frequently found foſſile. They are of different ſhapes, but the moſt common kind riſe into a ſemiorbicular form, and are hollow within, ſomewhat reſembling an acorn-cup: this hollow is found ſometimes empty, and ſometimes filled with the ſtratum in which it is immerſed. Many of them have an outer circle, of a different colour from the reſt.

LYCOPERDON, puff ball, in botany, a genus of funguſes, of a fleſhy ſubſtance like other muſhrooms, and roundiſh ſhape. They are ſometimes ſeſſile, and ſometimes ſtand on a thick pedicle: they produce ſeparate male and female flowers, contained in the cellular fungous ſubſtance; which remains a long time confuſed, and the fructifications not formed: and when they are formed and the cells diſtinct, it is but a very ſhort time before the very matter of the cells breaks to powder, and the ſeeds fall out of the cavities of the placentæ; and the whole matter, powder, ſeeds, and filaments, of the placentæ, are diſcharged altogether in form of a fine duſt.

LYCOPODIUM, wolf's claw-moſs, in botany, a genus of moſſes conſiſting of branches, furniſhed with leaves, and producing ſpikes formed of ſquamæ, of a different figure from the leaves; at the baſes of which are placed capſules, of a kidney-like ſhape, which have no cup or vagina; and, when ripe, open longitudinally into two parts, and diſcharge a great quantity of fine powder.

LYCOPUS, water hore-hound, in botany, a genus of plants, the flower of which conſiſts of a ſingle petal, with a cylindraceous tube, and a quadrifid limb: there is no fruit; the ſeeds, which are four, and roundiſh, being lodged in the cup.

LYING-TO, or LYING-BY, in navigation, arranging the ſails in ſuch a ſituation that they counteract each other nearly with equal effort, ſome of them drawing her forward, and others forcing her back; the effect of which is, that ſhe makes no way through the ſea, only a very little to the leeward. The intent of lying-by, in general, is to wait for ſome ſhip or boat which is approaching or expected; or in the night-time to prevent running on land, ſhoals, or in the way of danger apprehended to be near.

LYING-TO *in a Storm*, is going with a very little ſail to keep the ſhip from rolling violently, and is more properly expreſſed trying. See TRYING.

LYMPH, *Lympha*, a fine fluid, ſeparated in the body from the maſs of blood, and contained in peculiar veſſels.

Dr. Keil ſays, that the lymph being chemically examined, will be found to contain a great deal of volatile, but not fixed ſalt, ſome phlegm, ſome ſulphur, and a little earth. The uſe of the lymph, he obſerves, may be gathered from the conſideration of the parts into which it diſcharges itſelf: that which comes from the head, neck, and arms, is thrown into the jugular and ſubclavian veins; all the lymphatics which the parts in the cavity of the thorax ſend out, empty themſelves into the thoracic duct; and the lymph from all the reſt of the body, flows to the receptacle of the chyle; ſo that there can be no doubt but its chief uſe is to dilute and perfect the chyle before it mixes with the blood. Now the whole lymph which is ſeparated from the blood, being requiſite for this uſe, it is plain there could be no glands in the abdomen appropriated for the ſeparation of the whole lymph, but what muſt have had a very great ſhare of the blood

which paſſes through the aorta, in order to ſeparate ſo great a quantity of lymph; but the liver and kidneys requiring alſo a great quantity of blood, and which could not be avoided, nature choſe to ſeparate the lymph from the blood which goes to all the parts of the body, rather than appoint particular glands for it in the abdomen, which would have been more at hand, but would have robbed the other parts of a large quantity of blood, and occaſioned a very unequal diſtribution of it.

For the lymphatic glands, ſee the article GLAND.

There are three ſorts of veſſels which go by the name of lymphatics, whereas formerly that word was uſed to ſignify the tranſparent veſſels which accompany the lymphatic glands. The original ſources of theſe veſſels, Winſlow obſerves, are very difficult to be found out, and even their diſtribution through the body has not been ſufficiently traced, to enable us to deſcribe them particularly. As to their termination, we are ſure, that, for the moſt part, they end in the thoracic duct. Beſides theſe veſſels which accompany the glands, there are others, of the ſame ſtructure, found on the ſeveral viſcera, where no lymphatic glands have yet been diſcovered. We meet with them in very great numbers in the external membrane of the liver, and in the duplicature of the ſuperior membranous ligament of this organ. Several diſcoveries about theſe veſſels have been made in brutes.

The third ſort of veſſels termed lymphatic veſſels, are the ſmall arteries and veins which in the natural ſtate tranſmit only the ſerous part of the blood. Theſe veſſels differ from thoſe of the firſt, in the ſmallneſs of their diameter, and in their ſtructure and ſituation. All theſe little arteries and veins are uniform, extremely narrow, and though their ſides are not thinner than thoſe of the valvular lymphatics, yet their diameters are generally leſs. The other lymphatics are full of valves and very thin, but they are not narrow in proportion. The arterial and venous lymphatics are found on the parts which are naturally white, as on the ſkin, and the white of the eye; and their origin are eaſily diſcoverable; but the valvular lymphatics are confined to the internal parts of the body, and are found on the parts of all colours; but we cannot eaſily trace them to their original ſtate.

LYMPHATICS, or LYMPHEDUCTS, in anatomy, fine ſmall veſſels that convey the lymph.

LYNX, or OUNCE, in zoology, a ſpecies of the felis kind, with a truncated tail, a brown body ſpotted with black; the head is large, but not very long; the forehead is flat; the eyes are very large and fierce; the ears are very large and open, but they terminate in a point at the top, and are there ornamented with a pencil of fine black hairs; the mouth is furniſhed with very terrible teeth, and there are whiſkers about it, as alſo over the eyes; the neck is long and thick, the breaſt large and broad, the legs ſtrong, the claws terrible, the tail ſhort and abrupt; and the whole animal large and robuſt, ſomewhat leſs than the lion, very fierce, and remarkable for the quickneſs of its ſight.

LYRE, *Lyra*, a muſical inſtrument of the ſtring kind, much uſed by the ancients. See CITHARA.

The lyre, among poets, painters, ſtatuaries, carvers, &c. is attributed to Apollo and the Muſes.

LYRE, *Lyra*, in aſtronomy, a conſtellation of the northern hemiſphere, the number of whoſe ſtars in Ptolemy's and Tycho's catalogues are only ten, but nineteen in the Britannic catalogue.

LYRIC, in general, ſignifies ſomething ſung or played on the lyre: but it is more particularly applied to the ancient odes and ſtanzas, anſwering to our airs and ſongs, and may be played on inſtruments.

This ſpecies of poetry was originally employed in celebrating the praiſes of gods and heroes, though it was afterwards introduced into feaſts and public diverſions. Mr. Barnes ſhews how unjuſt it is to exclude heroic ſubjects from this kind of verſe, which is capable of all the elevation ſuch matters require. The characteriſtic of this kind of poetry is, according to Trapp, the ſweetneſs and variety of the verſe, the delicacy of the words and thoughts, the agreeableneſs of the numbers, and the deſcription of things moſt pleaſing in their own natures. At firſt the lyric verſe was only of one kind, but afterwards they ſo continued to vary the feet and numbers, that the variety of them now are almoſt innumerable.

This kind of poem is diſtinguiſhed from all other odes by the happy tranſitions and digreſſions which it beautifully admits, and the ſurpriſing and natural eaſy returns to the ſubject, which is not to be obtained without great judgment and genius.

The lyric is, of all kinds of poetry, the moſt poetical, and is as diſtinct, both in ſtyle and thought, from the reſt, as poetry is in general from proſe: it is the boldeſt of all other kinds, full of rapture, and elevated from common language the moſt that is poſſible: ſome odes there are likewiſe, in the free and looſe manner, which ſeem to avoid all method, and yet are conducted by a very clear one; which affect tranſitions ſeemingly without art, but for that reaſon have the more of it; which are above connection, and delight in exclamations and frequent invocations of the muſes; which begin and end abruptly, and are carried on through a variety of matter with a ſort of divine pathos, above rules and laws, and without regard to the common forms of grammar. Pindar has ſet his ſucceſſors the example of digreſſions and excurſions. To write a lyric poem are required not only a flowing imagination, brightneſs, life, ſublimity, and elegance, but the niceſt art and fineſt judgment, ſo as to ſeem luxuriant, and not be ſo; and under the ſhew of tranſgreſſing all laws, to preſerve them.

LYSIMACHIA, willow herb, in botany, a genus of plants, the corolla of which conſiſts of a ſingle petal; the tube is ſcarce diſcernible; the limb is divided into five ovato-oblong ſegments; the fruit is a capſule of a globoſe figure, compoſed of ten valves, and having only one cell; the ſeeds are numerous, and angulated, the receptacle globoſe, large, and punctuated.

M.

MAC

M, A liquid conſonant, and the twelfth letter of the alphabet.

The ſound of this letter is formed by ſhutting the lips, and thereby intercepting the breath, as it is ſtrongly expreſſed through the mouth and noſtrils jointly. Its ſound is always the ſame in Engliſh; it ſuffers no conſonant after it in the beginning of words and ſyllables, unleſs in ſome derived from the Greek, as *amneſty*, &c.

M, in preſcription, ſignifies a maniple, or handful; and at the end of a receipt it imports *miſce*, or mingle.

M, in aſtronomy, &c. denotes meridional, ſouthern; ſometimes *meridies*, or mid-day.

M, in law, the brand of a perſon convicted of manſlaughter, and admitted to the benefit of the clergy; it is burnt on the brawn of the left thumb.

M, among the ancients, was a numeral letter, ſignifying one thouſand; and when a daſh was added at the top of it as $\bar{M}$, it ſignified a thouſand times a thouſand.

MABBY, according to Mr. Boyle, is a kind of wine made from potatoes, and ſaid to be uſed in Barbadoes.

MACAO, or MACAW, in ornithology, a name given to the larger ſpecies of parrots with very long tails.

MACARONIC, or MACARONIAN, an appellation given to a burleſque kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue latinized.

MACCABEES, two apocryphal books of Scripture; ſo called from Judas Mattathias, ſurnamed Maccabeus. The firſt book of the Maccabees is an excellent hiſtory, and comes neareſt the ſtyle and manner of the ſacred hiſtorians of any extant. It contains the hiſtory of forty years, from the reign of Antiochus Epiphanes to the death of Simon the high-prieſt; that is, from the year of the world 3829 to the year 3869, 131 years before Chriſt. The ſecond book of the Maccabees begins with two epiſtles ſent from the Jews of Jeruſalem to the Jews of Egypt and Alexandria, to exhort them to obſerve the feaſt of the dedication of the new altar, erected by Judas on his purifying the temple. After theſe epiſtles follows the preface of the author to his hiſtory, which is an abridgement of a larger work, compoſed by one Jaſon, a Jew of Cyrene, who wrote the hiſtory of Judas Maccabeus, and his brethren, and the wars againſt Antiochus Epiphanes, and Eupator his ſon. The ſecond book does not, by any means, equal the accuracy and excellency of the firſt. It contains a hiſtory of about fifteen years, from the execution of Heliodorus's commiſſion, who was ſent by Seleucus to fetch away the treaſures of the temple, to the victory obtained by Judas Maccabeus over Nicanor; that is, from the year of the world 3828, to the year 3843, 147 years before Chriſt.

MACE, *Macis*, the ſecond coat or covering of the nutmeg.

It is a thin and flat membranous ſubſtance, of an oleaginous nature, a yelloviſh colour, extremely fragrant, and of a pleaſant, but acrid and oleaginous taſte. It is to be choſen new, not dry, and of a fragrant ſmell, tough, oleaginous, and of a good yellow.

MAC

Mace abounds with the ſame ſort of oil that is found in the nutmeg, but it is thinner in the mace, and is in a greater quantity. If the oil be ſeparated by diſtillation, what comes firſt over it is thin and limpid like water, and is of the moſt fragrant ſmell; what follows this is yellowiſh, and ſomewhat thicker; and, finally, a third comes over, if the fire be made more violent, which is reddiſh; and all three of theſe are ſo ſubtile and volatile, that, if they are not kept in veſſels very cloſe ſtopped, they will, in a great part, evaporate into the air, all their finer part flying off. An oil may alſo be drawn from mace, in the ſame manner as from nutmegs, and is of a ſomewhat ſofter conſiſtence.

Mace is carminative, ſtomachic, and aſtringent; it poſſeſſes all the virtues of the nutmeg, if taken in a larger doſe; and people have become delirious, for ſome hours, after an immoderate uſe of it. The oils of mace and nutmeg, whether prepared by diſtillation or by expreſſion, are ſo much of the ſame nature, that they may be indiſcriminately uſed for one another on all occaſions. They give eaſe in cholics, and often in nephritic caſes, taken internally from one drop to five or ſix of the diſtilled oil, or an unequal quantity of the expreſſed; and externally, they are of uſe to rub up paralytic limbs; they alſo aſſiſt digeſtion, and will often ſtop vomitings and hiccoughs, only by being rubbed on the regions of the ſtomach. The nurſes have a cuſtom of applying oil of mace, by expreſſion, to children's navels to eaſe their gripes, and that often with ſucceſs; and we are aſſured by authors of credit, that rubbed on the temples, it promotes ſleep. The oils, by diſtillation, are very properly added to the ſtronger cathartics in form of pills, and prove excellent correctives.

MACERATION, *Maceratio*, in pharmacy, an infuſion or ſoaking of ingredients in water, &c. in order either to ſoften them, or extract their virtues. It is a kind of digeſtion.

MACHINE, *Machina*, in general, whatever hath force ſufficient to raiſe or ſtop the motion of a heavy body.

Machines are either ſimple or compound; the ſimple ones are the ſeven mechanical powers, viz. lever, balance, pully, axis and wheel, wedge, ſcrew, and inclined plane. See MECHANICAL POWERS, LEVER, BALANCE, &c.

If the given power is not able to overcome the given reſiſtance when directly applied, that is, when the power applied is leſs than the weight or reſiſtance given; then the thing is to be performed by the help of a machine made with levers, wheels, pullies, ſcrews, &c. ſo adjuſted, that when the weight and power are put in motion on the machine, the velocity of the power may be at leaſt ſo much greater than that of the weight, as the weight and friction of the machine, taken together, is greater than the power. For on this principle depends the mechaniſm or contrivance of mechanical engines uſed to draw or raiſe heavy bodies, or overcome any other force; the whole deſign of theſe being to give ſuch a velocity to the power in reſpect of the weight, as that the momentum of the power may exceed the momentum of the

weight. For if machines are ſo contrived, that the velocity of the agent and reſiſtant are reciprocally as their forces, the agent will juſt ſuſtain the reſiſtant; but with a greater degree of velocity will overcome it. So that if the exceſs of velocity in the power is ſo great as to overcome all that reſiſtance which commonly ariſes from the friction or attrition of contiguous bodies, as they ſlide by one another, or from the coheſion of bodies that are to be ſeparated, or from the weights of bodies to be raiſed; the exceſs of the force remaining, after all theſe reſiſtances are overcome, will produce an acceleration of motion proportional thereto, as well in the parts of the machine, as in the reſiſting body. Now how a machine may be contrived to perform this to the beſt advantage, will appear from the following rules.

1 Having aſſigned the proportion of your power and the weight to be raiſed, the next thing is to conſider how to combine levers, wheels, pullies, &c. ſo that working together, they may be able to give a velocity to the power, which ſhall be to that of the weight ſomething greater than in the proportion of the weight to the power. This done you muſt eſtimate your quantity of friction, and if the velocity of the power be to that of the weight ſtill in a greater proportion than the weight and friction taken together is to the power; then your machine will be able to raiſe the weight. And note, this proportion muſt be ſo much greater, as you would have your engine work faſter.

2. But the proportion of the velocity of the power and weight muſt not be made too great neither: for it is a fault to give a machine too much power, as well as too little. For if the power can raiſe the weight and overcome the reſiſtance, and the engine perform its proper effect in a convenient time, and works well, it is ſufficient for the end propoſed. And it is in vain to make more additions to the engine to increaſe the power any further; for that would not only be a needleſs expence, but the engine would loſe time in working.

3. As to the power applied to work the engine, it may be either a living power, as men, horſes, &c. or an artificial power, as a ſpring, &c. or a natural power, as wind, water, fire, weights, &c.

When the quantity of the power is known, it matters not as to the effect what kind of power it is; for the ſame quantity of any ſort will produce the ſame effect. And different ſorts of powers may be applied in an equal quantity, a great variety of ways.

The moſt eaſy power applied to a machine is weight, if it be capable of affecting the thing deſigned. If not, then wind, water, &c. if that can conveniently be had, and without much expence.

A ſpring is alſo a convenient moving power for ſeveral machines. But it never acts equally as a weight does; but is ſtronger when much bent, than when but a little bent, and that in proportion to the degree of bending, or the diſtance it is forced to. But ſprings grow weaker by often bending, or remaining long bent; yet they recover part of their ſtrength by lying unbent.

The natural powers wind and water may be applied with vaſt advantage to the working of great engines, when managed with ſkill and judgment. The due application of theſe has much abridged the labours of men. For there is ſcarce any labour to be performed, but an ingenious artificer can tell how to apply theſe powers to execute his deſign, and anſwer his purpoſe. For any conſtant motion being given, it may, by a due application, be made to produce any other motions we deſire. Therefore theſe powers are the moſt eaſy and uſeful, and of the greateſt benefit to mankind. Beſides, they coſt nothing, nor require any repetition or renewing, like a weight or a ſpring, which require to be wound up. When theſe cannot be had, or cannot ſerve our end, we have recourſe to ſome living power, as men, horſes, &c.

4. Men may apply their ſtrength ſeveral ways in working a machine. A man of ordinary ſtrength, turning a roller by the handle, can act for a whole day, againſt a reſiſtance equal to thirty pounds weight. And if he works ten hours in a day, he will raiſe a weight of 30 lb. $3\frac{1}{2}$ feet in a ſecond; or if the weight be greater, he will raiſe it ſo much leſs in proportion.

But a man may act, for a ſmall time, againſt a reſiſtance of 50 lb. or more.

If two men work at a windlaſs, or roller, they can more eaſily draw up 70 lb. than one man can 30 lb. provided the elbow of one of the handles be at right angles to that of the other. And with a fly or heavy wheel applied to it, a man may do one-third part more work; and for a little while act with a force, or overcome a continual reſiſtance, of 80 lb. and work a whole day when the reſiſtance is but 40 lb.

Men uſed to carrying, ſuch as porters, will carry ſome 150 lb. others 200 or 250 lb. according to their ſtrength.

A man can draw but about 70 or 80 lb. horizontally; for he can but apply about half his weight.

If the weight of a man be 140 lb. he can act with no greater force in thruſting horizontally, at the height of his ſhoulders, than 27 lb.

A horſe draws to greateſt advantage, when the line of direction is a little elevated above the horizon, and the power acts againſt his breaſt; and can draw 200 lb. for eight hours in a day, at two miles and a half an hour. If he draws 240 lb. he can work but ſix hours, and not quite ſo faſt; and in both caſes, if he carries ſome weight, he will draw better than if he carried none. And this is the weight a horſe is ſuppoſed to be able to draw over a pully out of a well. In a cart, a horſe may draw 1000 lb. The moſt force a horſe can exert is when he draws ſomething above a horizontal poſition.

The worſt way of applying the ſtrength of a horſe, is to make him carry or draw up a hill. And three men, with 100 lb. on their backs, will climb up a ſteep hill faſter than a horſe with 300 lb.

A round walk for a horſe to draw in, at a mill, &c. ſhould not be leſs than forty feet diameter.

5. Every machine ought to be made of as few parts, and thoſe as ſimple as poſſible, to anſwer its purpoſe; not only becauſe the expence of making and repairing will be leſs, but it will alſo be leſs liable to any diſorder. And it is needleſs to do a thing with many, which may be done with fewer parts.

6. If a weight is to be raiſed but a very little way, the lever is the moſt ſimple, eaſy, and ready machine. Or if the weight be very great, the common ſcrew is moſt proper. But if the weight is to be raiſed a great way, the wheel and axle is a proper power, and blocks and pullies are eaſier ſtill; and the ſame may be done by help of the perpetual ſcrew.

Great wheels to be wrought by men or cattle are of moſt uſe and convenience, when their axles are perpendicular to the horizon; but if by water, &c. then it is beſt to have their axles horizontal.

7. As to the combination of ſimple machines together, to make a compound one; though the lever when ſimple cannot raiſe a weight to any great height, and in this caſe is of little ſervice; yet it is of great uſe when compounded with others. Thus the ſpokes of a great wheel are all levers perpetually acting; and a beam fixed to the axis to draw the wheel about by men, or horſes, is a lever. The lever alſo may be combined with the ſcrew, but not conveniently with pullies or with the wedge. The wheel and axle is combined with great advantage with pullies. The ſcrew is not well combined with pullies; but the perpetual ſcrew combined with the wheel is very ſerviceable. The wedge cannot be combined with any other mechanical power; and it only performs its effect by percuſſion; but this force of percuſſion may be increaſed by engines.

Pullies may be combined with pullies, and wheels with wheels. Therefore if any ſingle wheel would be too large, and take up too much room, it may be divided into two or three more wheels and trundles, or wheels and pinions, as in clock-work; ſo as to have the ſame power, and perform the ſame effect.

In wheels with teeth, the number of teeth which play together in two wheels ought to be prime to each other, that the ſame teeth may not meet at every revolution; for when different teeth meet, they by degrees wear themſelves into a proper figure: therefore they ſhould be contrived that the ſame teeth meet as ſeldom as poſſible.

8. The ſtrength of every part of the machine ought to be

be made proportional to the ſtreſs it is to bear. And therefore let every lever be made ſo much ſtronger, as its length and the weight it is to ſupport is greater; and let its ſtrength diminiſh proportionally from the fulcrum, or point where the greateſt ſtreſs is, to each end. The axles of wheels and pullies muſt be ſo much ſtronger as they are to bear greater weight. The teeth of wheels, and the wheels themſelves, which act with greater force, muſt be proportionally ſtronger. And in any combination of wheels and axles, make their ſtrength diminiſh gradually from the weight to the power, ſo that the ſtrength of every part be reciprocally as the velocity it has. The ſtrength of ropes muſt be according to their tenſion, and that is as the ſquares of their diameters. And in general whatever parts a machine is compoſed of, the ſtrength of every particular part of it muſt be adjuſted to the ſtreſs upon it; therefore in ſquare beams the cubes of the diameters muſt be made proportional to the ſtreſs they bear. And let no part be ſtronger or bigger than is neceſſary for the ſtreſs upon it: not only for the eaſe and well going of the machine, but for diminiſhing the friction. For all ſuperfluous matter in any part of it, is nothing but a dead weight upon the machine, and ſerves for nothing but to clog its motion. And he is by no means a perfect mechanic, that does not only adjuſt the ſtrength to the ſtreſs; but alſo contrive all the parts to laſt equally well, that the whole machine may fail together.

9. To have the friction as little as poſſible, the machine ought to be made of the feweſt and ſimpleſt parts. The diameters of the wheels and pullies ought to be large, and the diameters of the arbors or ſpindles they run on, as ſmall as can be conſiſtent with their ſtrength. All ropes and cords muſt be as pliable as poſſible, and for that end rubbed with tar or greaſe; the teeth of wheels muſt be made to fit and fill up the openings; and cut into the form of epicycloids. All the axles, where the motion is, and all teeth where they work, and all parts that in working rub upon one another, muſt be made ſmooth; and when the machine goes, muſt be oiled or greaſed.

10. When any motion is to be long continued, contrive the power to move or act always one way, if it can be done. For this is better and eaſier performed than when the motion is interrupted, and the power is forced to move firſt one way and then another; becauſe every new change of motion requires a new additional force to effect it. Beſides, a body in motion cannot ſuddenly receive a contrary motion, without great violence. And the moving any part of the machine contrary ways by turns, with ſudden jerks, tends only to ſhake the machine to pieces.

11. In a machine that moves always one way, endeavour to have the motion uniform.

12. But when the nature of the thing requires that a motion is to be ſuddenly communicated to a body, or ſuddenly ſtopped; to prevent any damage or violence to the engine, by a ſudden jolt, let the force act againſt ſome ſpring, or beam of wood, which may ſupply the place of a ſpring.

13. In regard to the ſize of the machine; let it be made as large as it can conveniently. The greater the machine the exacter it will work, and perform all its motions the better. For there will always be ſome errors in the making, as well as in the materials; and conſequently in the working of the machine. The reſiſtance of the medium in ſome machines has a ſenſible effect. But all theſe mechanical errors bear a leſs proportion to the motion of the machine in great machines than in little ones; being nearly reciprocally as their diameters; ſuppoſing they are made of the ſame matter, and with the ſame accuracy, and are equally well finiſhed: therefore in a ſmall machine they are more ſenſible; but in a great one almoſt vaniſh: therefore great machines will anſwer better than ſmaller, in all reſpects, except in ſtrength. For the greater the machine the weaker it is, and leſs able to reſiſt any violence.

14. For engines that go by water, it is neceſſary to meaſure the velocity and force of the water. To get the velocity, drop in pieces of ſticks, &c. and obſerve how far they are carried in a ſecond, or any given time.

But if it flows through a hole in a reſervoir, or ſtanding receptacle of water, the velocity will be found from the depth of the hole below the ſurface.

Thus let $s = 16\frac{1}{12}$ feet. $v =$ velocity of the fluid per ſecond. B = the area of the hole. H = height of the water; all in feet. Then the velocity $v = \sqrt{2s\,H}$; and its force = the weight of the quantity $\frac{vv}{2s}$ B or H B of water, or $= \frac{62\frac{1}{2}}{112}$ H B hundred weight: becauſe a cubic foot is $= 62\frac{1}{2}$ lb. avoird. Alſo a hogſhead is about $8\frac{1}{2}$ feet, or 531 lb. and a ton is four hogſheads.

When you have but a ſmall quantity of water, you muſt contrive it to fall as high as you can, to have the greater velocity, and conſequently more force upon the engine.

15. If water is to be conveyed through pipes to a great diſtance, and the deſcent be but ſmall; ſo much larger pipes muſt be uſed, becauſe the water will come ſlow.

Water ſhould not be driven through pipes faſter than four feet per ſecond, by reaſon of the friction of the tubes. Nor ſhould it be much wire-drawn, that is, ſqueezed through ſmaller pipes; for that creates a reſiſtance, as the water-way is leſs in narrow pipes.

16. When any work is to be performed by a water wheel moved by the water running under it and ſtriking the paddles or ladle boards. The channel it moves in ought to be ſomething wider than the hole of the adjutage, and ſo cloſe to the floats on every ſide, as to let little or no water paſs; and when paſt the wheel, to open a little that the water may ſpread. It is of no advantage to have a great number of floats or paddles, for theſe paſt the perpendicular are reſiſted by the back water, and thoſe before it are ſtruck obliquely. The greateſt effect that ſuch a wheel can perform, in communicating any motion, is when the paddles of the wheel move with $\frac{1}{3}$ the velocity of the water; in which caſe, the force upon the paddles is $\frac{4}{9}$ only; ſuppoſing the abſolute force of the water againſt the paddle, when the wheel ſtands ſtill, to be 1. So that the utmoſt motion which the wheel can generate, is but $\frac{4}{27}$ of that which the force of the water againſt the paddles at reſt, would produce. This is when the wheel is at the beſt; but oftentimes far leſs is done. *Emerſon's Mechanics.*

MACHINERY, in epic and dramatic poetry, is when the poet introduces the uſe of machines, or brings ſome ſupernatural being upon the ſtage, in order to ſolve ſome difficulty, or to perform ſome exploit out of the reach of human power. The ancient dramatic poets never made uſe of machines, unleſs where there was an abſolute neceſſity for ſo doing; whence the precept of Horace,

Nec Deus interſit, niſi dignus vindice nodus inciderit.

It is quite otherwiſe with epic poets, who introduce machines in every part of their poems; ſo that nothing is done without the intervention of the gods. In Milton's Paradiſe Loſt, by far the greater part of the actors are ſupernatural perſonages: Homer and Virgil do nothing without them; and in Voltaire's Henriade, the poet has made excellent uſe of St. Louis.

As to the manner in which theſe machines ſhould act, it is ſometimes inviſibly, by ſimple inſpirations and ſuggeſtions; ſometimes by actually appearing under ſome human form; and, laſtly, by means of dreams and oracles, which partake of the other two. However, all theſe ſhould be ſo managed as to keep within the bounds of probability.

MACKREL, in ichthyology, a ſpecies of ſcomber, with five pinnules at the extremity of the back, and a ſpine at the anus.

MACROCOSM, the great world, or univerſe.

The word is Greek μακροκοσμος, and derived from μακρος, great, and κοσμος, the world.

MACROLOGY, in rhetoric, a too copious ſtyle. See the article STYLE.

MACULÆ, in aſtronomy, dark ſpots appearing on the luminous faces of the ſun, moon, and even ſome of the planets; in which ſenſe they ſtand contradiſtinguiſhed from faculæ. See FACULÆ.

Theſe ſpots are moſt numerous and eaſily obſerved in the ſun. It is not uncommon to ſee them in various

forms, magnitudes, and numbers, moving over the ſun's diſk. They were firſt of all diſcovered by the Lyncean aſtronomer Galileo, in the year 1610, ſoon after he had finiſhed his new invented teleſcope. That theſe ſpots adhere to, or float upon, the ſurface of the ſun, is evident for many reaſons. 1. Many of them are obſerved to break out near the middle of the ſun's diſk; others to decay and vaniſh there, or at ſome diſtance from his limb. 2. Their apparent velocities are always greateſt over the middle of the diſk, and gradually ſlower from thence on each ſide towards the limb. 3. The ſhape of the ſpots varies according to their poſition on the ſeveral parts of the diſk: thoſe which are round and broad in the middle, grow oblong and ſlender as they approach the limb, according as they ought to appear by the rules of optics.

By comparing many obſervations of the intervals of time in which the ſpots made their revolution, by Galileo, Caſſini, Scheiner, Hevelius, Dr. Halley, Dr. Derham, and others, it is found that 27 days, 12 hours, 20 minutes, is the meaſure of one of them at a mean; but in this time the earth deſcribes the angular motion of 26° 22′, about the ſun's center: therefore ſay, as the angular motion of 360° + 26° 22′, is to 360°; ſo is 27 days, 12 hours, 20 minutes, to 25 days, 15 hours, 16 minutes; which, therefore, is the time of the ſun's revolution about its axis.

Had the ſpots moved over the ſun in right lined directions, it would have ſhewn the ſun's axis to have been perpendicular to the plane of the ecliptic; but ſince they move in a curvilinear path, it proves his axis inclined to the axis of the ecliptic, and it is found by obſervation, that the angle is equal to 7° 30′; that is, if BD (plate LXXXI. *fig.* 6.) paſſing through the center of the ſun C, be perpendicular to the plane of the earth's equator H I, then will the axis of the ſun's motion, A E, contain, with that perpendicular, the angle A C B = 7° 30′ = G C I, the angle which the equator of the ſun G F makes with the plane of the ecliptic: and the points in which a plane, paſſing through the perpendicular B D and axis A E, cuts the ecliptic, are in the eighth degree of piſces, on the ſide next the ſun's north pole A, and conſequently in the eighth degree of virgo, on the other ſide next the ſun's ſouth pole E. Scheiner had determined the angle B C A to be 7°, and Caſſini made it 8° by his obſervations, which is the reaſon why 7° 30′ is choſen for a mean.

As to the magnitude of the ſpots, they are very conſiderable, as will appear if we obſerve that ſome of them are ſo large as to be plainly viſible to the naked eye: thus Galileo ſaw one of them in the year 1612; and Mr. Martin aſſures us, that he knew two gentlemen that thus viewed them within a few years paſt; whence he concludes, that theſe ſpots muſt therefore ſubtend, at leaſt, an angle of one minute. Now the diameter of the earth, if removed to the ſun, would ſubtend an angle of but 20″; ſo that the diameter of a ſpot, juſt viſible to the naked eye, is, to the diameter of the earth, as 60 to 20, or as 3 to 1; and, therefore, the ſurface of the ſpot, if circular, to a great circle of the earth, is as 9 to 1: but four great circles are equal to the earth's ſuperficies; whence the ſurface of the ſpot is, to the ſurface of the earth, as 9 to 4, or as 2 $\frac{1}{4}$ to 1. Gaſſendus ſays, he ſaw a ſpot whoſe diameter was equal to $\frac{1}{30}$ of that of the ſun, and therefore ſubtended an angle at the eye of 1′ 3″; its ſurface was therefore 5 times larger than the ſurface of the whole earth.

What theſe ſpots are, it is preſumed, no body can tell; but they ſeem to be rather thin ſubſtances than ſolid bodies, becauſe they loſe the appearance of ſolidity in going off the diſk of the ſun: they reſemble ſomething of the nature of ſcum or ſcoria, ſwimming on the ſurface, which are generated and diſſolved by cauſes little known to us: but whatever theſe ſolar ſpots are, it is certain they are produced from cauſes very inconſtant and irregular; for Scheiner ſays he frequently ſaw fifty at once, but for twenty years after ſcarce any appeared. And in this century the ſpots were very frequent and numerous till the year 1741, when, for three years ſucceſſively, very few appeared; and now, ſince the year 1744, they have again appeared as uſual.

Theſe maculæ are not peculiar to the ſun, they have been obſerved in all the planets. Thus Venus was obſerved to have ſeveral by ſignior Bianchini, in the year 1726. As in Venus, ſo in Mars both dark and bright ſpots have been obſerved, firſt by Galileo, and afterwards by Caſſini, &c. Jupiter has had his ſpots obſervable ever ſince the invention and uſe of large teleſcopes. Saturn, by reaſon of his great diſtance on one hand, and Mercury, by reaſon of his ſmallneſs and vicinity to the ſun on the other, have not as yet had any ſpots diſcovered on their ſurfaces, and conſequently nothing in relation to their diurnal motions and inclinations of their axis to the planes of their orbits can be known, which circumſtances are determined in all the other planets, as well as in the ſun, by means of theſe maculæ. See the articles VENUS, MARS, and JUPITER.

The ſpots, or maculæ, obſervable on the moon's ſurface, ſeem to be only cavities or large caverns, on which the ſun ſhining very obliquely, and touching only their upper edge with his light, the deeper places remain without light; but as the ſun riſes higher upon them, they receive more light, and the ſhadow, or dark parts grow ſmaller and ſhorter, till the ſun comes at laſt to ſhine directly upon them, and then the whole cavity will be illuſtrated: but the dark, duſky ſpots, which continue always the ſame, are ſuppoſed to proceed from a kind of matter or ſoil which reflects leſs light than that of the other regions. See MOON.

MADDER, in commerce, is one of the aſperifolious ſtellated plants, or of thoſe which have rough narrow leaves ſet in form of a ſtar at the joints of the ſtalks. The root, which is the only part made uſe of, is long, ſlender, of a red colour both on the outſide and within, excepting a whitiſh pith which runs along the middle.

This plant was formerly cultivated among us in quantity for the uſe of the dyers, who for ſome time paſt have been ſupplied from Holland and Zealand: its culture is now again ſet on foot in this kingdom, under the laudable encouragement of a public ſociety. There are ſome exotic plants which degenerate in our climate, as alkanet; but this is not the caſe with madder, that produced in England being equal to the beſt that is brought from abroad.

The method of cultivating this uſeful plant, as practiſed by the Dutch, is as follows.

In autumn they plow the land, where they intend to plant madder in the ſpring, and lay it in high ridges, that the froſt may mellow it; in March they plow it again; and at this ſeaſon they work it very deep, laying it up in ridges eighteen inches aſunder, and about a foot high; then about the beginning of April, when the madder will begin to ſhoot out of the ground, they open the earth about their old roots, and take off all the ſide-ſhoots, which extend themſelves horizontally, juſt under the ſurface of the ground, preſerving as much root to them as poſſible: theſe they tranſplant immediately upon the tops of the new ridges, at about a foot apart, obſerving always to do this when there are ſome ſhowers, becauſe then the plants will take root in a few days, and will require no water.

When the plants are growing, they carefully keep the ground hoed, to prevent the weeds from coming up between them; for if they are ſmothered by weeds, eſpecially when young, it will either deſtroy or weaken them ſo much, that they ſeldom do well after. In theſe ridges they let the plants remain two ſeaſons, during which time they keep the ground very clean; and at Michaelmas, when the tops of the plants are decayed, they take up the roots, and dry them for ſale.

This is what I could learn of their method of cultivating this plant; to which I will ſubjoin a few obſervations of my own, which I have ſince made upon the culture of madder in England. And, firſt, I find there is no neceſſity for laying the ground up in ridges in England, as is practiſed by the Dutch, eſpecially in dry land, becauſe the places where I ſaw it, were very wet land, which is often floated in winter; ſo that, if the plants were not elevated upon ridges, their roots would rot in winter. Secondly, they ſhould be planted at a greater diſtance in England; the rows ſhould be at leaſt three feet diſtant, and the plants eighteen inches aſunder in the rows: for as they extend themſelves pretty far under ground, ſo where

where they are planted too near, their roots will not have room to grow. And thirdly, I find, that if all the horizontal roots are deſtroyed from time to time, as they are produced, it will cauſe the large downright roots to be much bigger, in which the goodneſs of this commodity chiefly conſiſts: for if the upper roots are ſuffered to remain, they will draw off the principal nouriſhment from the downright roots, as I have experienced; for I planted a few roots upon the ſame ſoil and ſituation, which were of equal ſtrength, and rooted equally well: half of theſe I hoed round, and cut off the horizontal roots, and the other half I permitted the horizontal roots to remain on; and when I took them all up, thoſe which I had hoed about, and kept clear from horizontal roots, were almoſt as large again as the other, and the roots were double the weight; which plainly proves it neceſſary to cut off thoſe ſuperfluous roots: ſo that where this plant is cultivated in quantity, it will be an excellent method to uſe the hoeing-plough, to ſtir the ground, and deſtroy the weeds; for with this inſtrument a large quantity of ground may be kept clean at a ſmall expence: and as this will ſtir the ground much deeper than a common hoe, it will cut the ſuperficial roots, and thereby improve the principal roots.

The crop of madder ſhould be ſhifted into freſh land; for the ground which has had one crop, will not be fit to receive another in leſs than four years; during which time any other annual crop may be cultivated on the land. *Miller.*

When the madder roots are arrived at perfection, they are taken up, well dried, and then reduced to powder by the following mill.

Deſcription of a mill at Liſle, in Flanders, for pulveriſing madder. Plate LXXXIII. *fig.* 1. repreſents the parts of a madder mill: it is inſulated, and covered only by a ſlight thatch. The figures 2, 3, 4, 5, and 6, are ſupplementary to the firſt: we muſt have recourſe to them in our explanation of the parts of the mill: they are therefore diſtinguiſhed by the ſame letters, and each piece is repreſented apart.

A is a lever, or pole, nine feet eight inches long, and ſix inches by four in magnitude. B, the axis of the wheel, ſix feet four inches ſix lines high, and nine or ten inches diameter. C, ſtays, or knees, four feet ſix inches long, and four or five inches ſquare. D, the cogged wheel, three feet one inch ſix lines ſemi-diameter, and furniſhed with fifty-ſeven cogs.

The fellies, or circumference of this wheel, muſt be eight inches by four large: they are ſecured by an iron hoop. The traverſes are ſix inches by four thick, pinned and keyed. The cogs are made of apple-tree wood, and project three inches three lines: they are two inches and a half by two, at their inſertion, and two inches and a half by one at the top: and beneath the wheel they are two inches long, and one and a half ſquare: they act on the rounds of the trundle-head about one inch and a half of their length. The pins that faſten them are alſo apple-tree wood.

E is a beam twelve inches ſquare. F, the trundle-head, thirteen inches ſemi-diameter, furniſhed with eighteen rounds, each a foot long, and two inches diameter: the ends of this trundle-head are two inches and a half thick, and hooped with iron. There are alſo two iron bars pinned on to ſecure the joints of the wood.

G is another axle-tree, or turning-beam, eighteen feet ſix inches ſix lines long, ten inches ſquare near the trundle-head, and fourteen inches diameter in its octogonal part. H, liſters four inches nine lines long, five inches broad, two inches and a half thick. Hence it is apparent, that there are fifteen lifters inſerted into the axle-tree, to ſerve five beetles; that is, three to each. For this reaſon the lifters, the catches, and the peſtles, are diſtinguiſhed by the ſame figure.

K, flyers four feet five inches long, and four inches ſquare: they are loaded with lead at their ends. L catches, which anſwer to the lifters, H: they project five inches nine lines, and are five inches broad and two and a half thick.

M, other catches inſerted into the ſides, or thickneſs of the beetles, N, and anſwer to the levers, Q, N, beetles ten feet four inches long, and four inches ſquare. They are rounded at the end next the mortars, and ſhod with an iron foot four inches diameter, which may be ſeen in figure 6. The beetles are numbered in this manner, 1, 4, 2, 5, 3, (*fig.* 1.) to ſhew the order in which they play when the machine is in motion. O, croſs-bars ſix inches by four, which ſupport the joints, P.

P, joints eight inches long, ſix wide and four thick. An iron pin, keyed, paſſes through each joint, and ſupports a moveable lever, Q, which acts on the catch, M, when the peſtle, N, is to be kept up. Q, levers, two feet three inches ſix lines long, three inches thick, by four wide.

R, keeps, ſix or eight inches wide to prevent the beetles from being diſordered. S, an upright poſt four inches ſquare, in which the croſs-bars and keeps are inſerted. T, mortars cut in a ſingle piece of wood ſixteen inches ſquare: they are eleven inches deep, and their greateſt diameter is ſeven inches: the bottom is lined with lead three or four lines thick.

V, a trough to prevent waſte, over which hangs a cloth, faſtened above to the keep, whilſt the mill is at work.

X, a beam twelve inches ſquare; this beam, and that at the other end, marked E, reſt on the timber work that ſupports the roof. The ſockets and pivots may be ſo well comprehended by the plate, that letters of reference were thought unneceſſary: the ſockets are braſs, the pivots ſteel.

We have purpoſely omitted giving the dimenſions of every part, to avoid confuſion; but the machine may be eaſily conſtructed by attending to the deſcription we have given, which is very exact.

But though the mill deſcribed above, is now actually employed in grinding or pulverizing madder at Liſle; yet it labours under ſeveral imperfections, which we ſhall endeavour to point out, and deſcribe a mill conſtructed in a more perfect manner.

There will be however no occaſion to deſcribe the wheel work of this mill; it being the ſame as that of Liſle: it will be ſufficient to give the proportion of the parts which compoſe it. The pole, or lever, from the center of the axis of the cogged wheel, to the part where the links of the ſpring-tree bar are faſtened, is nine feet long; the wheel is five feet ſemi-diameter, and has ſeventy-two cogs; the trundle-head is ten inches ſemi-diameter to the center of the rounds, and has twelve rounds; thus it makes ſix turns to one of the wheel. The horſe, going three feet in a ſecond, makes three rounds and a half in a minute, and the trundle-head twenty. The axle-tree having on its circumference three lifters to every beetle, each beetle makes ſix ſtrokes in a minute, and the four two hundred and forty in the ſame ſpace. The ſquare part of the axle-tree, on which the trundle-head is fixed, is made out of a piece of wood five inches ſemi-diameter; the other part of the axle-tree is larger, being ſeven inches ſemi-diameter. It is neceſſary it ſhould be ſo large, that the tenons of the lifters may have a proper length and thickneſs: it is much better to be round than an octogon, or any other faced form, as the mortiſes may be more regularly made. From the end of the lifters to the center of the axle-tree is twelve inches; ſo that in their motion they form a circle two feet diameter: the upper face of theſe lifters is cut in a curve, the radii of which are tangents to the circumference of the abovementioned circle; the largeſt of theſe tangents is twelve inches, and determines the greateſt riſe of the beetles. By the liſters being thus curved, the reſiſtance is equal, at whatever height the beetles may be, as they are always in contact with the lifters at the ſame diſtance from their center of gravity. As there are on the length of the axle-tree twelve lifters in four parts, they form, one with the other, angles of thirty degrees, ſuppoſing them to be ſeen one behind the other, as if inſerted on the ſame plane: on this account, when the firſt beetle is raiſed to half its height, the ſecond is about to riſe; the firſt quitting the liſter, the third is on the point of riſing, &c. We ſay, on the point, becauſe we are to obſerve, that the lifters go under the catches, or under that which ſupplies their place, five or ſix lines; and that the greateſt tangent of the curve, being twelve inches, is leſs, by near ſeven lines, than the ſixth part of the circumference of the circle, and gives the firſt beetle

time to quit the lifter before the third riſes: this is neceſſary, that the power may never have more than two beetles to act upon.

The front of the frame-work is that ſide before which the axle-tree turns. The frame-work conſiſts of two beams, ten feet long, and eight inches ſquare: betwixt them, at each end, is a traverſe quarter, ſix inches by four. In the middle of the length and width of the beams, riſe two uprights, which are mortiſed and pinned: they are twelve feet eight inches high without their tenons, fourteen inches wide, and ſix inches thick, ſupported by a brace mortiſed into the front at the height of two feet, at the back part four feet and a half. Betwixt theſe two uprights is the block on which the beetles fall: it is made of a piece of dry tough elm, four feet and a half long betwixt the uprights, to which it is joined by a dove-tail two inches thick, and as much deep: it is twenty inches high, and eighteen broad: it reſts the whole breadth of its ends on the edge of the beams, and betwixt them, on three pieces of wood, at equal diſtances, that lie on the brick work, which ſupports the whole. The block is divided croſs-ways, by a partition two inches thick, parallel with the uprights, and of the ſame breadth, fixed into the block by two tenons, and in a groove wide enough to receive its whole thickneſs; the ſame is obſerved in the back part of the firſt keep, which is fixed: the upper-end is, in like manner, fixed to the upper-keep: this partition divides the block croſs-ways into two troughs, each twenty inches long, formed by two ſloping planks; ſo that the troughs are four inches and a half wide at the bottom within, eleven inches and a half at the top, and twelve inches perpendicularly high: and to prevent the loſs of the light duſt that riſes in the work, the ſpace betwixt the edge of the troughs, and the firſt keep, is boarded up; the boards at the back-part, as well as the ſides of the troughs there, are faſtened with grooves and dove-tails into the uprights and partition; thoſe before lift up in a groove like a ſaſh, and are faſtened by turn-buckles; the fronts of the troughs take entirely off; the pulverized root is taken out with a wooden ſpoon, and a feather broom, and they let it fall on a ſhelf before, which has a ledge four inches high; the fronts of the troughs are then put on again, and are filled with branch-madder; the ſliding-ſhutters are pulled down, and the peſtles are ſet at liberty to work, which had before been ſtopped whilſt the troughs were emptied; this takes but little time in doing; and the mill continues going during the time they gather up the root, and bolt or ſift it. There are two keeps, which ſerve to direct the beetles: the under part of the firſt is three feet, and the under part of the ſecond ten feet: above the block they are three inches and a half thick; the firſt is made level in the front with the back of the groove, that the ſliding-ſhutters may reſt on it when they are raiſed. Each keep conſiſts of two parts; thoſe at the back are let into the uprights, and pinned to them, and ſtrongly faſtened to the partition: thoſe in the front are made to take down, and put up, as occaſion ſerves; they ſlide in the grooves of the uprights, and thoſe that run along the middle of the partition: they have, beſides, two pins, by which they are kept in their places.

The beetles are, at the lower part, twelve inches wide, eighteen inches high, and four inches thick; ſo that their face, or bottom, contains forty-eight ſquare-inches: the upper part, or ſtock of each peſtle, is eight feet and a half long, four inches wide, and three thick; ſo that in the whole, they are ten feet long, without compriſing the cutters, which are four inches long, and formed like a carpenter's chiſſel: the blades of them are two inches and a half wide, and the tongues three inches and a half long: there are ſeventeen to each beetle. There are no catches, becauſe the lifters being in contact with their extremity, always at the ſame diſtance, five inches from the center of gravity of the beetles, the reſiſtance occaſioned by the friction of the ſtocks in the keeps, would have been very conſiderable. To avoid this inconvenience, a mortiſe twenty-five inches long, and three inches wide, is made in the face of the ſtocks of the peſtles, ſtrengthened on the ſides by cheeks two inches thick. The upper parts of theſe mortiſes are ſix feet above the block; that is, on a level with the center of the axle-tree: this part is lined with a plate of copper, ſtrongly ſcrewed, well poliſhed, and rounded at the edge, to facilitate the fall of the beetles. On the ſide of the beetle-ſtock, ſixteen inches below the upper keep, are fixed catches a full inch thick, two inches high, and projecting four inches, to keep the beetles up whilſt the troughs are emptying.

The levers, which ſerve for this purpoſe, are placed behind, and reſt on ſhoulders fixed on a piece of wood, which bears by its two ends on two brackets, mortiſed and pinned into the two uprights, and ſupported by braces: theſe pieces are ſix inches ſquare. The levers are made of quarter-ſtuff, ſix inches and a half ſquare, as well as the lifters of the axle-tree. The upper face of the ſhorteſt arm of the lever is rounded like the lifters, in a curve deſcribed by the original circle, the radius of which is the ſpace from the middle of the catch to the center of motion of the lever, which ſhould be parallel to the bottom of the catch. The radius of this circle, as well as the greateſt of the curve, ſhould be fifteen inches, that the beetle, being raiſed thirteen or fourteen inches, may not ſlip off. That the levers may be the ſtronger, the wood muſt not be croſs grained; and in the center of motion, it ſhould be traverſed by a ſquare iron bar, projecting two inches on each ſide: theſe projections, being rounded into pivots, reſt on the ſhoulders in braſs ſockets. A cord is faſtened to the ſhorteſt arm, and the end of it is faſtened occaſionally to wooden pins at the back of the block, to keep the levers ſomewhat lower than the catches, whilſt the beetles are at work. The longeſt arm leſſens by degrees towards the end, till it is reduced to a ſquare: at this part is fixed another cord, which is faſtened to the ſame wooden pins, when the beetles are to be kept up. The above deſcription, with figures on the copper-plate, will be ſufficient for an ingenious mechanic to conſtruct a mill of this kind, which will doubtleſs be of great advantage to this kingdom, as conſiderable quantities of madder are now planted, and ſome of it fit for uſe.

Madder root gives out its colour both to water and to rectified ſpirit: the watery tincture is of a dark dull red, the ſpirituous of a deep bright one. Taken internally, for it has ſometimes been uſed medicinally as an aperient and diuretic, it tinges the urine red. In the Philoſophical Tranſactions, and in the Memoirs of the French Academy, there are accounts of its producing a like effect upon the bones of animals, to whom it had been given with their food: all the bones, particularly the more ſolid ones, were changed both externally and internally to a deep red, but neither the cartilaginous or fleſhy parts ſuffered any alteration. Some of theſe bones, macerated in water for many weeks together, and afterwards ſteeped and boiled in ſpirit of wine, loſt nothing of their colour, nor communicated any tinge to the liquors.

Madder imparts to woollen-cloth, prepared with alum and tartar, a very durable, though not a very beautiful red dye. As it is the cheapeſt of all the red drugs that give a durable colour, it is the principal one commonly made uſe of for ordinary ſtuffs. Sometimes its dye is heightened by the addition of Brazil-wood; and ſometimes it is employed in conjunction with the dearer reds, as cochineal, for demiſcarlets and demicrimſons. Mr. Hellot, from whoſe *Art de Teindre* the remaining part of this account is extracted, informs us, that thoſe who dye the beſt madder reds are particularly careful to keep the liquor of a heat conſiderably below boiling, increaſing the fire only towards the end, ſo as to make it boil for a minute or two juſt before the cloth is taken out, to confirm the dye. A boiling heat enables water to extract not only the red but a tawny or browniſh matter, which debaſes the red to a dull brick colour.

The proportion of madder is, about half the weight of the cloth. The beſt proportion of ſalts for preparing the cloth to receive the dye, ſeems to be, five parts of alum, and one of red tartar, for ſixteen of the ſtuff; which is to be boiled with theſe for two hours or longer, then kept moiſt for ſome days, and afterwards digeſted with the madder.

A variation in the proportion of the ſalts varies the colour communicated by the madder; and not only the ſhade but the ſpecies of colour. If the alum be diminiſhed and

and the tartar increaſed, the dye proves a red cinnamon: if the alum be entirely omitted, the red is deſtroyed, and a very durable tawny cinnamon is produced.

On boiling the dyed cloth in weak alcaline ley, great part of the colour is deſtroyed, and the remainder appears of a dirty or a kind of fallow hue: ſolution of ſope, on the other hand, diſcharges a part, and leaves the remaining red more lively than before.

Volatile alcalies heighten the red colour of madder, but at the ſame time render it fugitive like themſelves: madder prepared with lime and urine, after the manner practiſed for archil, loſt its red colour on attempting to dye with it, and communicated to the cloth only permanent nut colours.

If a pure red, as that of cochineal, be applied on cloth which has been previouſly dyed blue, and afterwards prepared for receiving this red by boiling with alum and tartar, a purple or violet will be produced, according as the blue or the red prevail. The madder red has not this effect; for as its colour is not a pure red, but is tarniſhed by the tawny matter which its woody fibres have in common with other roots; it gives upon blue only a cheſnut dye, more or leſs deep according to the deepneſs of the blue applied firſt.

There are, however, means of obtaining from madder a fine purple, without the addition of any other colouring drug. A piece of white woollen cloth, weighing half an ounce, was boiled for half an hour with ten grains of Roman alum, and ſix grains of cryſtals of tartar, and then taken out, ſqueezed, and ſuffered to cool. Twenty-four grains of bunch madder were added to the ſame liquor; and after the madder had given out its colour, twenty drops of a ſolution of biſmuth, made in ſpirit of nitre diluted with equal its weight of water, were dropt in. The cloth was now dipt again, and in half an hour taken out, ſqueezed, and waſhed: it appeared of a crimſon colour, nearly as beautiful as if it had been dyed with cochineal. To try the effect of loading it further with the colouring matter, it was returned into the liquor and boiled for a quarter of an hour longer: it had now acquired a purple colour ſufficiently vivid.

On varying this experiment, by keeping the cloth moiſt for ſome days after the preparation with alum and tartar, then dipping it in a plain decoction of madder made as uſual without ſalts; and adding, when it had gained a bright cinnamon colour, the ſame ſolution of biſmuth, the dye, inſtead of a purple, proved only a cheſnut.

The charge of erecting a kiln for drying, and a mill for pulverizing the madder roots, induced Mr. Dambourney to try how far the green root would anſwer the purpoſes of dyeing without any previous preparation. "I therefore, ſays this ingenious gentleman, waſhed them well that no earth might remain upon them: but having myſelf experienced that, as Mr. Du Hamel obſerves, this root loſes ſeven eights of its weight when it is dried ſufficiently to be reduced into powder, I judged that I muſt proportion my quantity accordingly. I therefore put into a quantity of liquor which would have required a pound of powdered madder, eight pound of freſh roots bruiſed in a mortar, and with this I dyed ſome cotton, in the uſual way. When the dyeing was finiſhed, I found that the liquor was ſtill over-charged, though the cotton had imbibed ſo deep a dye as to require two boilings to bring it down to the uſual colour: upon which I repeated the experiment with ſix pounds, and afterwards with four pounds, and I found that this laſt proportion of undried roots is that which gives a colour equal to what is extracted from a pound of dried and powdered madder. One half of the quantity of roots commonly uſed may therefore be ſaved by dyeing with them when they are freſh dug: but though this is a great ſaving, it is not the only one.

"1. There is no need to build kilns or ſheds for drying the roots in changeable weather.

"2. One is exempted from the inconveniences of a too haſty or too ſlow drying, either of which is equally hurtful to the quality of the madder.

"3. The waſte occaſioned by the peeling, garbling, winnowing, &c. of the roots, in the doing of which many if not all of the ſmall ones, that are not for example thicker than ſtraws, are ſeparated with the refuſe parts, and thereby generally loſt, is hereby ſaved.

"4. The expence of grinding is ſaved, together with the waſte and fraud which may be committed at the mill; and likewiſe the inconvenience of waiting till the mill is at liberty, which is of no ſmall conſequence in places where there are not mills appropriated to the grinding of madder only.

"5. Laſtly, the roots thus uſed do not evaporate or ferment, as the powdered madder always does if it be not ſpeedily uſed.

"All theſe advantages put together may be deemed equivalent to a ſaving of five eights in the quantity. The planter who knows how to dye may reap the benefit of them the moment that his roots are large enough to be taken up: the dyers by trade will by degrees be ſenſible of the advantage, and ſhare the profit with the planter, when the madder grounds are near them: they will even find themſelves under a neceſſity of ſo doing whenever this method ſhall become general, and this will be the means of rendering it ſuch; for as there is no particular time to be waited for in order to the madder's acquiring maturity, after it has been planted eighteen months; the huſbandman who carries a parcel of freſh roots to market will be ſure of ſelling them in that ſtate, and the dyer may buy them daily, in proportion to the quantity he wants; or he may agree with the planter for ſuch and ſuch quantities to be delivered to him at ſuch and ſuch times.—I have moreover experienced that theſe roots may be kept freſh during ſeveral months, by laying them in a hole three feet deep, in alternate layers of roots and of earth."

MADNESS, *Mania*, a moſt dreadful kind of delirium without a fever.

Melancholy and madneſs may very juſtly be conſidered as diſeaſes nearly allied; for they have both the ſame origin, that is, an exceſſive congeſtion of blood in the brain: they only differ in degree, and with reſpect to the time of invaſion; melancholy being the primary diſeaſe, of which madneſs is the augmentation. Both theſe diſorders ſuppoſe a weakneſs of the brain, which may proceed from an hereditary diſpoſition; from violent diſorders of the mind, eſpecially long continued grief, ſadneſs, anxiety, dread, and terror; from cloſe ſtudy and intenſe application of mind to one ſubject; from narcotic and ſtupefying medicines; from previous diſeaſes, eſpecially acute fevers; from a ſuppreſſion of hæmorrhages, and omitting cuſtomary bleeding; from exceſſive cold, eſpecially of the lower parts, which forces the blood to the lungs, heart, and brain; and from violent anger, which will change melancholy into madneſs.

It is evident from obſervation, that the blood of maniac patients is black, and hotter than in the natural ſtate; that the ſerum ſeparates more ſlowly and in a leſs quantity than in healthy perſons; and that the excrements are hard, of a dark red or greyiſh colour, and the urine light and thin.

The antecedent ſigns of madneſs are a redneſs and ſuffuſion of the eyes with blood; a tremulous and inconſtant vibration of the eye-lids; a change of diſpoſition and behaviour; ſupercilious looks, a haughty carriage, diſdainful expreſſions, a grinding of the teeth, and unaccountable malice to particular perſons: alſo little ſleep, a violent head-ach, quickneſs of hearing, incredible ſtrength, inſenſibility of cold; and, in women, an accumulation of blood in the breaſts, in the increaſe of this diſorder.

Diſeaſes of the mind have ſomething in them ſo different from other diſorders, that they ſometimes remit for a long time, but return at certain periods, eſpecially about the ſolſtices. It may likewiſe be obſerved, that the raving fits of mad people, which keep the lunar periods, are generally accompanied with epileptic ſymptoms.

This diſeaſe, when it is primary or idiopathic, is worſe than the ſymptomatic, that accompanies the hyſteric or hypochondriac paſſion, which is eaſily cured; as is that alſo which ſucceeds intermitting fevers, a ſuppreſſion of the menſes, of the lochia, of the hæmorrhoids, or which is occaſioned by narcotics. When the paroxyſms are ſlight in the idiopathic kind, the cure is not very difficult; but if it is inveterate, and has but ſhort remiſſions, it is almoſt incurable. Sometimes this diſeaſe terminates by

critical excretions of blood from the noſe, uterus, or anus; ſometimes diarrhœas and dyſenteries will terminate theſe diſorders; and puſtules, ulcers, and the itch have alſo done the ſame. As to the cure, bleeding is the moſt efficacious of all remedies; and where there is a redundance of thick grumous blood, a vein is firſt to be opened in the foot, a few days after in the arm; then in the jugular vein, or one in the noſtrils with a ſtraw; and laſt of all the frontal vein, with a blunt lancet, for fear of hurting the pericranium. Tepid baths made of rain or river-water are alſo convenient; and before the patient enters the bath, he ſhould have cold water poured on his head. Purgatives are likewiſe uſeful; but the lenient are to be preferred to the draſtic: thus manna, caſſia, rhubarb, cream of tartar, or tartar vitriolate, are moſt convenient, when the diſeaſe ariſes from the hypochondriac paſſion, a ſtagnation of the blood in the inteſtines, or in the ramifications of the vena portæ, eſpecially when taken in decoctions and infuſions at repeated intervals, ſo as to operate in an alterative manner. Some kinds of mineral waters are alſo highly efficacious in melancholy and madneſs: but nothing is better for removing the cauſe of theſe diſorders, than depurated mercury. Particular medicines among vegetables, are balm, betony, vervain, brooklime, ſage, worm-blood, flowers of St. John's wort, of the lime-tree, and camphire: from animals, aſs's blood: among minerals, ſteel, cinnabar, ſugar of lead, and the calx and tincture of ſilver. Hoffman is of opinion, that nothing better deſerves the name of a ſpecific in theſe diſeaſes than motion and exerciſe, when duly proportioned to the ſtrength of the body. Sedative medicines are good, but not opiates and narcotics, for theſe induce ſtupidity and folly: thoſe that are good in an epilepſy, will be here beneficial, ſuch as caſtor, ſhavings of hartſhorn, the roots and ſeeds of piony, antiepileptic powders, the valerian root, flowers of the lily of the valley and of the lime-tree. Boerhaave ſays, the principal remedy for raving madneſs is dipping in the ſea, and keeping the patient there as long as he can bear it. As a high degree of the itch has terminated theſe diſorders, it may be proper to make iſſues in the back; but bliſters, contrary to Shaw's opinion, are prejudicial; for by ſtimulating the nervous membranes and the dura mater, they increaſe the ſpaſmodic ſtricture, and the motion of the groſs and bilious blood through the head and the other parts of the body.

As to diet, the patient ſhould carefully abſtain from ſalt and ſmoked fleſh, whether beef or pork; from ſhell fiſh; from fiſh of a heavy and noxious quality; from aliments prepared with onions and garlic: all which generate a thick blood. He ſhould, in general, eat no more than is ſufficient to ſupport nature. Small beer, or cold pure water, are the beſt drink; but ſweet and ſtrong wines are highly prejudicial, as is alſo exceſſive ſmoking tobacco. Change of air and travelling may be beneficial.

For the madneſs proceeding from the bite of a mad dog, ſee HYDROPHOBIA.

MADREPORA, in botany, a genus of ſubmarine plants, of a ſtony hardneſs, but ſomewhat approaching to the form of other vegetables. It is compoſed of a main ſtem, and ſubdivided into a number of branches, which are full of holes or pores, in a radiated form.

MADRIER, in the military art, a long and broad plank of wood, uſed for ſupporting the earth in mining and carrying on a ſap, and in making coffers, caponiers, galleries, and for many other uſes at a ſiege. Madriers are alſo uſed to cover the mouths of petards, after they are loaded, and are fixed with the petards to the gates or other places deſigned to be forced open.

MADRIGAL, in the Italian, Spaniſh, and French poetry, is a ſhort amorous poem, compoſed of a number of free and unequal verſes, neither confined to the regularity of a ſonnet, nor to the point of an epigram, but only conſiſting of ſome tender and delicate thought, expreſſed with a beautiful, noble, and elegant ſimplicity. The madrigal is uſually conſidered as the ſhorteſt of all the leſſer kinds of poetry, except the epigram: it will admit of fewer verſes than either the ſonnet or the roundelay; no other rule is regarded in mingling the rhimes, and the different kinds of verſe, but the fancy and convenience of the author: however, this poem allows of leſs licence than many others, both with reſpect to rhime, meaſure, and delicacy of expreſſion.

MÆMACTERION, *μαιμακτηριων*, in ancient chronology, the fourth month of the Athenian year, conſiſting of only twenty-nine days, and anſwering to the latter part of September and the beginning of October.

MAGAS, in ancient muſic, the name of two inſtruments, the one a ſtringed kind, and the other a kind of flute, which is ſaid to have yielded very high and very low ſounds at the ſame time.

MAGAS alſo ſignifies the bridge of any inſtrument.

MAGAZINE, a place in which ſtores are kept of arms, ammunition, proviſions, &c. Every fortified town ought to be furniſhed with a large magazine, which ſhould contain ſtores of all kinds, ſufficient to enable the garriſon and inhabitants to hold out a long ſiege, and in which ſmiths, carpenters, wheelwrights, &c. may be employed in making every thing belonging to the artillery, as carriages, waggons, &c.

MAGAZINE *of a Ship of War*, a ſmall ſtore-houſe in the after or fore-part of a ſhip's hold, where the gunpowder is ſtowed, and filled into cartridges, bombs, grenadoes, &c. by the gunner and his mates, ready for engagement.

MAGDALEN, or *Nuns of St. Magdalen*, an order of religious in the Romiſh church, dedicated to St. Mary Magdalen, and ſometimes called Magdalenettes. Theſe chiefly conſiſt of courtezans, who quitting their profeſſion, devote the reſt of their lives to repentance and mortification.

MAGI, or MAGIANS, an ancient religious ſect in Perſia, and other Eaſtern countries, who maintained, that there were two principles, the one the cauſe of all good, the other the cauſe of all evil; and abominating the adoration of images, worſhipped God only by fire, which they looked upon as the brighteſt and moſt glorious ſymbol of Oromaſdes, or the good god; as darkneſs is the trueſt ſymbol of Arimanius, or the evil god. This religion was reformed by Zoroaſter, who maintained that there was one ſupreme independent Being; and under him two principles or angels, one the angel of goodneſs and light, and the other of evil and darkneſs: that there is a perpetual ſtruggle between them, which ſhall laſt to the end of the world; that then the angel of darkneſs and his diſciples ſhall go into a world of their own, where they ſhall be puniſhed in everlaſting darkneſs; and the angel of light and his diſciples ſhall alſo go into a world of their own, where they ſhall be rewarded in everlaſting light.

The prieſts of the magi were the moſt ſkilful mathematicians and philoſophers of the ages in which they lived, inſomuch that a learned man and a magian became equivalent terms. The vulgar looked on their knowledge as more than natural, and imagined them inſpired by ſome ſupernatural power: and hence thoſe who practiſed wicked and miſchievous arts, taking upon themſelves the name of magians, drew on it that ill ſignification which the word magician now bears among us.

This ſect ſtill ſubſiſts in Perſia, under the denomination of Gaurs, where they watch the ſacred fire with the greateſt care, and never ſuffer it to be extinguiſhed. See the article GAURS.

MAGIC originally ſignified only the knowledge of the more ſublime parts of philoſophy; but as the magi likewiſe profeſſed aſtrology, divination, and ſorcery, the term magic became odious, being uſed to ſignify an unlawful diabolical kind of ſcience, acquired by the aſſiſtance of the devil and departed ſouls. See the articles ASTROLOGY, DIVINATION, NECROMANCY, &c.

Natural magic is only the application of natural philoſophy to the production of ſurpriſing, but yet natural effects. The common natural magic, found in books, gives us only ſome childiſh and ſuperſtitious traditions of the ſympathies and antipathies of things, or of their occult and peculiar properties; which are uſually intermixed with many trifling experiments, admired rather for their diſguiſe than for themſelves. See EXPERIMENTAL PHILOSOPHY.

MAGIC *Lantern*, in optics. See *Magic* LANTERN.

MAGIC *Square*, a ſquare figure formed of a ſeries of numbers in arithmetical progreſſion, diſpoſed into ſuch parallel

parallel and equal ranks, as that the ſums of each row, as well diagonally as laterally, ſhall be equal.

MAGISTERY, in chemiſtry, commonly denotes a white powder, prepared of certain ſubſtances by precipitation. Theſe ſubſtances are either of the mineral kind, as earth, ſtones, &c. or vegetables, as herbs, reſins, &c. or animals, as bones, horns, and cruſtaceous parts.

The method of preparing it is thus; take the ſubſtance from which you deſign to prepare the magiſtery, and bruiſe or break it groſly; then pour thereon a proper liquor, an acid, &c. in order to its ſolution or extraction. The ſolution is precipitated by an affuſion of the liquor, or by the matter by whoſe force that of the ſolvent is blunted: the precipitated powder may be waſhed, if neceſſary, with common water, and afterwards gently dried. *Schroder.*

MAGISTERY *of Biſmuth* is made by diſſolving biſmuth in ſpirit of nitre, and pouring on it ſalt water, which precipitates the magiſtery to the bottom.

MAGISTERY *of Lead* is made by diſſolving ſaccharum ſaturni in diſtilled vinegar, and then precipitating it with oil of tartar per deliquium.

MAGISTERY *of Reſins*, or reſinous extracts of ſcammony, jalap, &c. are made by diſſolving the matter in ſpirit of wine, and precipitating it with water.

Mr. Boyle takes magiſtery to conſiſt in a preparation of a body, whereby it is converted, by means of ſome additament, into a body of a different kind, as when iron or copper is turned into cryſtals of Mars and Venus.

MAGISTRATE, any public officer to whom the executive power of the law is committed, either wholly, or in part.

MAGNA CHARTA, the great charter of the liberties of England, and the baſis of our laws and privileges.

This charter may be ſaid to derive its origin from king Edward the Confeſſor, who granted ſeveral privileges to the church and ſtate, by charter: theſe liberties and privileges were alſo granted and confirmed by king Henry I. by a celebrated great charter, now loſt; but which was confirmed or re-enacted by king Henry II. and king John. Henry III. the ſucceſſor of this laſt prince, after having cauſed twelve men to make enquiry into the liberties of England in the reign of Hen. I. granted a new charter, which was the ſame as the preſent magna charta; this he ſeveral times confirmed, and as often broke; till in the thirty-ſeventh year of his reign, he went to Weſtminſter-hall, and there, in the preſence of the nobility and biſhops, who held lighted candles in their hands, magna charta was read, the king all the while holding his hand to his breaſt, and at laſt ſolemnly ſwearing faithfully and inviolably to obſerve all the things therein contained, &c. then the biſhops extinguiſhing the candles, and throwing them on the ground, they all cried out, "Thus let him be extinguiſhed, and ſtink in hell, who violates this charter." It is obſerved, notwithſtanding the ſolemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war againſt him, when, after various ſucceſs, he confirmed this charter, and the charter of the foreſt, in the fifty-ſecond year of his reign. This excellent charter, ſo equitable and beneficial to the ſubject, is the moſt ancient written law in the kingdom: by the 25 Edw. I. it is ordained, that it ſhall be taken as the common law; and by the 43 Edward III. all ſtatutes made againſt it are declared to be void.

MAGNESIA, or MANGANESE, in natural hiſtory. See MANGANESE.

MAGNESIA ALBA, in the materia medica, a fine white earth, ſoluble readily in all acids, the vitriolic as well as the others, into a bitter purgative liquor; and not convertible by fire into quicklime.

This earth has not hitherto been found naturally pure or in a ſeparate ſtate: it was for ſeveral years a celebrated ſecret in the hands of ſome particular perſons abroad, till its preparation was made public by Lanciſi in the year 1717, and afterwards by Hoffman in 1722. It was then extracted from the mother-ley, or the liquor which remains after the cryſtallization, of rough nitre; either by precipitation with a ſolution of fixed alcaline ſalt; or by evaporating the liquor, and calcining the dry reſiduum, ſo as to diſſipate the acids, by which the earth had been made diſſoluble.

The magneſia, in this mother-ley, appears to have proceeded from the vegetable aſhes, which are either made ingredients in the compoſitions from which nitre is obtained, or elſe added to the elixation of the nitre: for the aſhes of different woods, burnt to perfect whiteneſs, and freed from their alcaline ſalt, were found to be of the ſame nature with the true magneſia. But as quicklime alſo, in moſt of the German, French, and other European nitre-works, is commonly employed in large quantity, the earth obtained from the mother-ley's of thoſe works is rather a calcareous earth than magneſia. What is now brought from abroad, under the name of magneſia, gives plain proofs of its calcareous nature, by its burning into quicklime, and forming a ſelenites with the vitriolic acid.

The true magneſia is obtained in great purity, from a filtered ſolution of ſal catharticus amarus; by adding a filtered ſolution of any alcaline ſalt, till a freſh addition produces no further milkineſs. The white earth, which precipitates, is to be waſhed by repeated affuſions of hot as well as cold water, and then dried for uſe.

The magneſia is recommended by Hoffman as an uſeful antacid, a ſafe and inoffenſive laxative in doſes of a dram or two, and a diaphoretic and diuretic, when given in ſmaller doſes, as fifteen or twenty grains. Since this time, it has of late come into great eſteem among us, particularly in heart-burns, and for preventing or removing the many diſorders which children are thrown into from a redundance of acid humours in the firſt paſſages. It is preferred, on account of its laxative quality, to the teſtaceous and other abſorbent earths, which, unleſs gentle purgatives are given occaſionally to carry them off, are apt to lodge in the body, and occaſion a coſtiveneſs very detrimental to infants. It muſt be obſerved, however, that it is not the magneſia itſelf which proves laxative, but the ſaline compound reſulting from its coalition with acids: if there are no acid juices in the ſtomach to diſſolve it, it has no ſenſible operation, and in ſuch caſes it may be rendered purgative by drinking any kind of acidulous liquors after it. All the other known ſoluble earths yield with acids, not purgative, but more or leſs aſtringent compounds.

MAGNET, *Magnes*, loadſtone, in natural hiſtory, a very rich iron ore, found in large detached maſſes, of a duſky iron grey, often tinged with browniſh or reddiſh, and when broken appearing ſomething like the common emery, but leſs ſparkling. It is very heavy, conſiderably hard, of a perfectly irregular and uneven ſurface, and of a firm ſtructure, but uſually with ſome porous irregularities within. It is found in England, and all other places where there are iron mines.

The word is derived from a city in Lydia, called Magneſia, where this ſtone was firſt found.

This famous ſtone was well known to the ancients, but ſcarce any other property of it than that of its attracting iron, as we may ſee in Pliny B. 36. c. 16. However, it appears, that they knew ſomething of its communicating virtue, particularly Plato, when deſcribing that famous chain of iron rings put together, the firſt of which was held by a magnet; and Lucretius makes mention of the ſame magnetic quality operating through the hardeſt bodies.

But we do not ſee by any paſſage in their writings, that they knew any thing of the directive virtue of the loadſtone: and we are utterly in the dark as to the time this diſcovery was firſt made, as alſo when it was applied to the uſe of navigation. It, however, appears, that this diſcovery was made before the year one thouſand one hundred and eighty.

The primary properties of the loadſtone are the following: 1. Every loadſtone has two points, called poles, which emit the magnetic virtue. 2. One of theſe poles attracts, the other repels iron, but no other body. 3. This virtue, being the third ſpecies of attraction, is communicated to iron very copiouſly by the touch, which renders it ſtrongly magnetic. 4. A piece of iron ſo touched by the loadſtone, and nicely ſuſpended on a ſharp point, will be determined to ſettle itſelf in a direction nearly north and ſouth. 5. The end of the needle touched by the ſouth pole of the ſtone, will point northwards; and the contrary. 6. Needles touched by the

the ſtone, will dip below the horizon, or be directed on the touched part to a point within the earth's ſurface: this is called the dipping needle. 7. This virtue may alſo be communicated to iron by a ſtrong attrition all one way. 8. Iron rods or bars acquire a magnetic virtue by ſtanding long in one poſition. 9. Fire totally deſtroys this virtue, by making the ſtone or iron red hot. 10. This power is exerted ſenſibly to the diſtance of ſeveral feet. 11. It is ſenſibly continued through the ſubſtance of ſeveral contiguous bodies or pieces of iron. 12. It pervades the pores of the hardeſt body. And, 13. equally attracts the iron in vacuo as in open air. Theſe and many more are the properties of a body, not more wonderful than uſeful to mankind. See the articles POLE, NEEDLE, VARIATION, &c.

There is a very curious method of rendering viſible the directions which the magnetic effluvia take in going out of the ſtone: thus, let A B, C D, (plate LXXXI. *fig.* 7.) be the poles of the ſtone; about every ſide gently ſtrew ſome ſteel-filings on a ſheet of white paper; theſe ſmall particles will be affected by the effluvia of the ſtone, and ſo poſited as to ſhew the courſe and direction of the magnetic particles on every part: thus, in the middle of each pole, between A B, and C D, it appears to go nearly ſtraight on; towards the ſides it proceeds in lines more and more curved, till at laſt the curved lines from both poles meeting and coinciding, form numberleſs curves on each ſide, nearly of a circular figure, as repreſented in the diagram. This ſeems to ſhew that the magnetic virtue emitted from each pole, circulates to, and enters the other.

The cauſe of the variation of the needle has remained hitherto without any demonſtrative diſcovery; yet ſince its declination, and inclination, or dipping, (ſee the article DIPPING NEEDLE,) do both of them manifeſtly indicate the cauſe to be ſomewhere in the earth, it has given occaſion to philoſophy to frame hypotheſes for a ſolution, which makes the earth a large or general magnet or loadſtone, of which all the leſſer ones are but ſo many parts or fragments, and being poſſeſſed of the ſame virtue, will, when left to move freely, have the ſame diſpoſition and ſimilarity of poſition, and other circumſtances.

The moſt conſiderable of theſe hypotheſes is that of the late ſagacious Dr. Halley, which is this; the globe of the earth is one great magnet, having four magnetical poles or points of attraction, near each pole of the equator two; and that in thoſe parts of the world which lie near adjacent to any one of thoſe magnetical poles, the needle is chiefly governed thereby, the neareſt pole being always predominant over the more remote one. Of the north poles, that which is neareſt to us he ſuppoſes to be in the meridian of the land's end, which governs the variations in European Tartary, and the North Sea; the other he places in a meridian paſſing through California, about 15 degrees from the north pole of the world, which governs the needle in North America, and the oceans on either ſide. In like manner he accounts for the variations in the ſouthern hemiſphere. See Philoſophical Tranſactions, N°. 148.

The variation of the needle from the north and ſouth points of the horizon, not being the ſame but variable in different years, and in a diverſe manner, in different parts of the earth, made the doctor farther conjecture, that two of the magnetic poles were fixed, and two moveable; and in order to make this out, he ſuppoſes the external part of the earth to be a ſhell or cortex, containing within it a magnetic moveable nucleus of a globular form, whoſe center of gravity is the ſame with that of the earth, and moveable about the ſame axis.

Now, if the motions of both the ſhell and nucleus were the ſame, the poles of each would always have the ſame poſition to each other; but he ſuppoſes the motion of the nucleus to be a very ſmall matter leſs than that of the ſhell, which yet is ſcarce ſenſible in 365 revolutions; and, if ſo, the magnetic poles of the nucleus will by ſlow degrees change their diſtance from the magnetic poles of the ſhell, and thus cauſe a variation in that needle's variation, which is governed by the moveable pole of the nucleus, while that variation which reſpects the fixed poles of the magnetic ſhell remains more conſtant; as in Hudſon's-bay the change is not obſerved to be near ſo faſt as in theſe parts of Europe.

The variation of the needle has within a century paſt undergone a remarkable alteration; for at London it was obſerved by Mr. Burrows in the year 1580, to be 11° 15′ eaſt; that is, if N. S. (*fig.* 8) repreſent the north and ſouth points of the horizon, and E. W. the eaſt and weſt points, the needle then had the ſituation A B, ſo that the arch B N = 11° 15′. After that, in the year 1622, it was obſerved by Mr. Gunter to be but 6° eaſt. In the year 1634, Mr. Gellibrand obſerved it to be 4° 5′ eaſt. In 1657, it was obſerved by Mr. Bond to be nothing at all, that is, the needle placed itſelf in the ſituation S, N, and pointed directly to the north. After this, in the year 1672, Dr. Halley obſerved it to be 2° 30′ weſtward; and again, in the year 1692, he found it 6° weſt. Since then, in the year 1722, Mr. Graham, by moſt accurate experiments, found it to be 14° 13′, and at preſent it is between 19 and 20 degrees; and in ſome places it has been found to be 23° weſtward.

The variation of the declination and inclination of the needle is variable and ſubject to no regular computation. What the quantity of both ſorts of variation is in the ſeveral parts of the world, is ſhewn in Dr. Halley's map of the world, improved from the obſervations of Mr. Pound.

The law of magnetic attraction ſeems not yet aſcertained. Sir Iſaac Newton ſuppoſes it to decreaſe nearly in the triplicate ratio of the diſtance; but Dr. Helſham, trying the experiment by his loadſtone, found it to be as the ſquares of the diſtances inverſely; and Mr. Martin aſſures us, that the power of his loadſtone decreaſes in a different manner from either, it being in the ſeſquiplicate ratio of the diſtances inverſely: for exactneſs, he made a ſquare bar of iron juſt a quarter of an inch thick, and then provided three pieces of wood of the ſame form and thickneſs exactly; then poiſing the loadſtone very nicely at the end of a ballance, which would turn with leſs than a grain, he placed under it the iron with firſt one piece of wood, then two pieces; and laſtly, all three pieces upon it; by which means the ſteel-points of the pole were kept at ¼, ½, ¾, of an inch from the iron; and in thoſe diſtances the weights put into the oppoſite ſcale, to raiſe the loadſtone from the wood, which is touched while the beam was horizontal, were as follows:

	Grains	Rat. of Sq.	Rat. of Cub.	S. Rat.
Diſtances ¼	156	156	56	156
½	58	39	19	56
¾	28	17	6	30

Whence it appears that the number of grains to counteract the power of the loadſtone in theſe diſtances, approach very near, and are almoſt the ſame with thoſe which are in the ſeſquiplicate ratio, but are widely different from thoſe which are in the duplicate ratio; and this experiment Mr. Martin tried ſeveral times for each diſtance, with ſcarce any variation in the ſucceſs.

The ingenious Muſchenbroek has, with indefatigable pains and application, made experiments of the attractions and repulſions of loadſtones in reſpect to iron and to each other, but could never find any regular proportion in the increaſe of attraction in their approach to, or decreaſe of attraction in their receſs from one another; only that the force of the magnetic virtue did increaſe in the approach to, and diminiſh in the receſs from the ſtone, but not exactly as the diſtance, nor as the ſquare or cube of the diſtance, nor as the ſquare or cube of the diſtance reciprocally; nor in any proportion reducible to numbers; and therefore he very reaſonably conjectures, that the repulſions and attractions diſturb one another, ſo as to confound the proportion; nor are we able to hope for any other rule concerning this matter, till a way be found, if ever it can be, of ſeparating the attracting from the repelling parts.

The power or force of magnets is generally greater in ſmall than in large ones, in proportion to their bulk. It is very rare that very large ones will take up more than three or four times their own weight, but a ſmall one is but tolerably good that will take up no more than eight, ten, or twelve times its weight. The honourable Mr. Berkeley has one whoſe weight is but 43 grains, which will

Iron Weight.

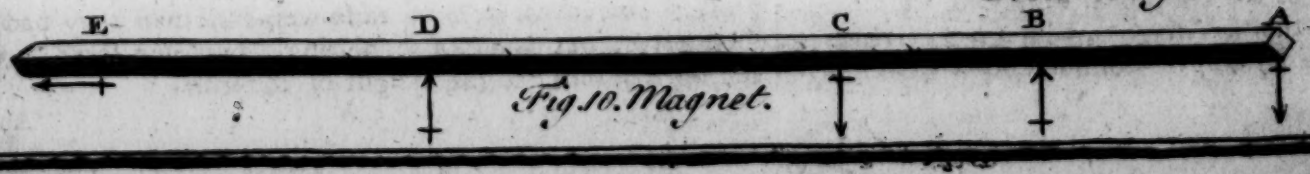

Fig. 10. Magnet.

will take up 1032 grains, which is 24 times its weight; but that of Mr. Newton, which he bears in his ring, inſtead of a diamond, weighs ſcarce three grains, will take up 746 grains, which is 250 times its weight, which is by far the beſt and ſtrongeſt it is preſumed ever ſeen; and therefore, as a curioſity, we have given a cut of the ring and ſtone with the iron hanging to it. (*fig.* 9.)

Iron bars, by ſtanding long in the ſame poſition, will acquire the magnetic virtue to a ſurpriſing degree. There have been ſeen one about 10 feet long and three inches thick, ſupporting the ſummer-beam of a room, which has been able to turn the needle at 8 or 10 feet diſtance, and exceeded a loadſtone of 3½ pounds weight. From the middle point upwards it was a north-pole, and downwards a ſouth-pole; and Mr. Martin ſays he has now by him an iron rod, which has ſeveral poles or parts which change the poſition of the magnetic needle. This rod was the beam of a large ſteel-yard, which let A E (*fig.* 10.) repreſent; then at A, and from thence to B, the ſouth end of the needle is attracted; at B, and from thence to C, the ſouth end is repelled, and the north end attracted; from C to D, the ſouth end is again attracted, and the north end repelled. Laſtly, at the end E begins another pole, and there the needle ſtands nearly parallel with the beam, with neither end attracted.

The poles of a loadſtone are not to be looked upon as two ſuch invariable points as never to change place; for according to Mr. Boyle, the poles of a little bit of magnet may be changed by applying them to the more vigorous poles of another, as has been confirmed by Dr. Knight, who can change at pleaſure the poles of a natural magnet, by means of iron bars magnetically impregnated. Upon gently cutting a magnet through the middle of its axis, each piece becomes a compleat magnet; for the parts that were contiguous under the equator before the magnet was cut, become poles, and even poles of different names; ſo that each piece may become equally a north or ſouth-pole, according as the ſection was made nearer the ſouth or north-pole of the large magnet; and the ſame thing would happen in any other ſub-diviſions. But upon cutting a magnet longitudinally, there will then be four poles, the ſame as before the cutting; only that there ſhall be formed in each piece a new axis parallel to the former, and more or leſs in the inſide of the magnet. We find by experience, that two magnets attract each other by the poles of different denominations; whereas, on the contrary, the two ſimilar poles repel each other.

By a great number of experiments we alſo learn that the form of a magnet in attraction and repulſion reaches ſometimes farther, ſometimes not ſo far. The activity of ſome reaches to 14 feet, and that of others is inſenſible within 8 or 9 inches; the ſphere of activity is greater on certain days than on others, without its ever appearing that the heat, moiſture, or drought of the air contribute any thing to this effect.

It has been found that the poles of the ſame denomination in magnets, and the caſe is the ſame in bodies magnetically impregnated, repel each other, while they are at a mean diſtance from the limits of their ſphere of activity, and on the contrary attract each other in the point of contact; there are other magnets that repel each other with greater vigour towards the middle of their ſphere of activity than near the point of contact, where it ſeems the repulſion diminiſhes: yet Mr. Mitchel pretends to have obſerved, by means of artificial magnets, that the two poles attract and repel equally at the ſame diſtances, and in all kinds of direction; that the error of thoſe who believed the repulſion to be weaker than the attraction was owing to this, that magnets and magnetical bodies are always weakened, by bringing the poles of the ſame denomination near each other; whereas their virtue is increaſed, when the poles of different denominations are brought near each other; that this augmentation or diminution of force, occaſioned by the proximity of two magnets, becomes inſenſible, in proportion as they are removed from each other: for which reaſon we ſee that at a great diſtance attraction and repulſion approach more and more to an equality, and are reciprocally removed from equality, in proportion as the reciprocal diſtance of two magnets diminiſhes; ſo that if a magnet, which is pretty ſtrong and pretty nigh to it, impair conſiderably a weak magnet that approaches it by the poles of the ſame denomination, it ſhall happen that the pole of this laſt ſhall be deſtroyed and changed into a pole of a different denomination, by means of which repulſion will be converted into attraction. In ſhort, by many experiments Mr. Mitchel was convinced, that attraction and repulſion increaſe and decreaſe in the inverſe ratio of the ſquares of the reſpective diſtances of the two poles.

All theſe effects of natural repulſion and attraction find no obſtacle from ſolids or fluids, the wind, flame, or the current of waters; and they are as lively in common air, as in that which is rarefied or condenſed in the air-pump.

The magnet attracts iron with ſtill greater force than it does another magnet; and this attraction extends to all bodies that contain ferrugineous particles.

No ſolid or fluid body can any way hinder the mutual action of iron and a magnet upon each other unleſs it be iron itſelf: nor does the exceſſive heat of iron diminiſh theſe effects, though the exceſſive heat of a magnet diminiſh its virtue, at leaſt for a time.

The attraction of a magnet newly dug out of a mine, makes it to take up only very ſmall pieces of iron; for which reaſon it muſt be armed, in order to augment its force: beſides this, the arming it unites, directs, and condenſes its virtue towards its poles, and cauſes its emanations to tend entirely towards the maſs which is laid thereon.

When you have determined where the poles are, which you may exactly find by placing over the magnet a very fine ſhort needle, which will ſtand perpendicular over each pole, and no where elſe; then you muſt file it very ſmooth at its poles, ſo that the axis ſhall have the greateſt length, yet without too much diminiſhing its other dimenſions. To determine the proportions of the armour, the greater the force of the magnet is, the thicker muſt the pieces of ſteel be of which it is to conſiſt; and for this purpoſe try the magnet with ſeveral ſteel-bars, and the greater weight it takes up with a ſteel-bar on, that bar is to be its armour. Though the attraction of an armed magnet appears conſiderable, yet very weak cauſes deſtroy its effect in a moment; for inſtance, when an oblong piece of iron is attracted under the pole of an excellent magnet, and the pole of a different denomination in another magnet that is weaker is preſented to the lower end of this piece of iron, this weaker magnet will very ſtrongly take away the iron. In like manner, if the point of a needle be put under one of the poles of a magnet ſo as to hang by its head, and preſent to this head any bar of iron by its upper end, the needle will immediately quit the magnet, in order to adhere to the bar; but if the needle hold by its head to the pole of the magnet, then neither the bar of iron, nor a weak magnet ſhall diſengage it; and there is another ſlight circumſtance which makes an armed and vigorous loadſtone appear to have no more force, and that is the too great length of the iron which is to be raiſed by one of the poles.

In order to communicate the magnetic virtue effectually, theſe methods are made uſe of. 1. It has been diſcovered that iron rubbed upon one of the poles of the magnet, acquires a great deal more virtue than from any other part thereof, and this is more conſiderable from an armed than a naked magnet. 2. The more gently the iron is preſſed, and the more it is preſſed againſt the pole, the more magnetical it becomes. 3. It is more convenient to impregnate iron on one pole than on both ſucceſſively. 4. The iron is much better impregnated by preſſing it uniformly, and in the ſame direction, according to its length, than by rubbing it by the middle; and the extremity which touches the pole laſt, retains the moſt virtue. 5. A piece of poliſhed ſteel, or a bit of pointed iron, receives more virtue than a ſimple piece of iron of the ſame figure; and, *cæteris paribus*, a piece of iron that is long, ſmall, and pointed, is more ſtrongly impregnated than that of any other form.

The communication of the magnetic virtue does not ſenſibly impair that of the loadſtone; though it has been obſerved, that ſome magnets have communicated a greater power to iron to raiſe weights, than they had themſelves, but without impairing their own force, or adding any thing to the weight of the iron.

As ſeveral ways have been propoſed for recovering the decayed virtue of loadſtones, but to little purpoſe, eſpecially that of keeping the ſtone conſtantly in ſteel filings, we ſhall here relate the remarkable experiment of Mr. Haac for this purpoſe, as it was attended with great ſucceſs. This gentleman had a magnet weighing fourteen ounces and a half, armed, which would take up ſixteen times its own weight; but having laid it by for ſome years unuſed, it loſt one fourth part of its virtue, or more; whereupon he hung as much weight to the ſtone as it would ſuſtain, and ſo left it for ſome weeks; then returning, he applied more weight to the former, which it very eaſily bore, and then repeating the addition of more weight at ſeveral periods, in the ſpace of about two years, he found that the ſtone had not only recovered its former ſtrength, but increaſed it ſo far, that it would now take up more than twenty pounds, whereas at firſt it would not take up fifteen.

Artificial MAGNET, a ſteel bar impregnated with the virtues of the magnet, ſo as to poſſeſs all the properties, and be uſed inſtead of the natural loadſtone.

There have been ſeveral methods propoſed for making artificial magnets, but none has yet met with greater ſucceſs than that of Mr. Canton's, a gentleman well known to the learned world, and to whom we owe this diſcovery.

Procure a dozen of bars, ſix of ſoft ſteel, each three inches long, one quarter of an inch broad, and one twentieth of an inch thick; with two pieces of iron, each half the length of one of the bars, but of the ſame breadth and thickneſs: alſo ſix pieces of hard ſteel, each five inches and a half long, half an inch broad, and three twentieths of an inch thick; with two pieces of iron of half the length, but the whole breadth and thickneſs of one of the hard bars; and let all the bars be marked with a line quite round them at one end. Then take an iron poker and tongs, (pl. LXXXII. *fig.* 3.) or two bars of iron, the larger they are and the longer they have been uſed, the better; and fixing the poker upright between the knees, hold to it, near the top, one of the ſoft bars, having its marked end downwards, by a piece of ſewing ſilk, which muſt be pulled tight by the left hand, that the bar may not ſlide: then graſping the tongs with the right hand, a little below the middle, and holding them nearly in a vertical poſition, let the bar be ſtroked by the lower end from the bottom to the top, about ten times on each ſide, which will give it a magnetic power ſufficient to lift a ſmall key at the marked end; which end, if the bar was ſuſpended on a point, would turn towards the north, and is therefore called the north pole, and the unmarked end is, for the ſame reaſon, called the ſouth pole. Four of the ſoft bars being impregnated after this manner, lay the two (*fig.* 1.) parallel to each other, at the diſtance of one fourth of an inch, between the two pieces of iron belonging to them, a north and a ſouth pole againſt each piece of iron: then take two of the four bars already made magnetical, and place them together ſo as to make a double bar in thickneſs, the north pole of one even with the ſouth pole of the other; and the remaining two being put to theſe, one on each ſide, ſo as to have two north and two ſouth poles together; ſeparate the north from the ſouth poles at one end by a large pin, and place them perpendicularly with that end downward on the middle of one of the parallel bars, the two north poles towards its ſouth, and the two ſouth poles towards its north end: ſlide them backward and forward three or four times the whole length of the bar, and removing them from the middle of this, place them on the middle of the other bar as before directed, and go over that in the ſame manner; then turn both the bars the other ſide upwards, and repeat the former operation: this being done, take the two from between the pieces of iron, and placing the two outermoſt of the touching bars in their room, let the other two be the outermoſt of the four to touch theſe with; and this proceſs being repeated till each pair of bars have been touched three or four times over, which will give them a conſiderable magnetic power, put the half dozen together after the manner of the four, (*fig.* 2.) and touch with them two pair of the hard bars placed between their irons, at the diſtance of about half an inch from each other; then lay the ſoft bars aſide, and with the four hard ones, let the other two be impregnated, (*fig.* 5.) holding the touching bars apart at the lower end near two tenths of an inch, to which diſtance let them be ſeparated after they are ſet on the parallel bar, and brought together again before they are taken off; this being obſerved, proceed according to the method deſcribed above, till each pair have been touched two or three times over; but as this vertical way of touching a bar will not give it quite ſo much of the magnetic virtue as it will receive, let each pair be now touched once or twice over in their parallel poſition between the irons, (*fig.* 6.) with two of the bars held horizontally, or nearly ſo, by drawing at the ſame time the north of one from the middle over the ſouth end, and the ſouth of the other from the middle over the north end of a parallel bar; then bringing them to the middle again, without touching the parallel bar, give three or four of theſe horizontal ſtrokes to each ſide. The horizontal touch, after the vertical, will make the bars as ſtrong as they poſſibly can be made, as appears by their not receiving any additional ſtrength, when the vertical touch is given by a great number of bars, and the horizontal by thoſe of a ſuperior magnetic power. This whole proceſs may be gone through in about half an hour; and each of the large bars, if well hardened, may be made to lift twenty-eight troy ounces, and ſometimes more. And when theſe bars are thus impregnated, they will give to an hard bar of the ſame ſize its full virtue in leſs than two minutes; and therefore will anſwer all the purpoſes of magnetiſm in navigation and experimental philoſophy much better than the loadſtone, which is known not to have a ſufficient power to impregnate hard bars. The half dozen being put into a caſe (*fig.* 4.) in ſuch a manner as that two poles of the ſame denomination may not be together, and their irons with them as one bar, they will retain the virtues they have received: but if their power ſhould, by making experiments, be ever ſo far impaired, it may be reſtored without any foreign aſſiſtance in a few minutes. And if, out of curioſity, a much larger ſet of bars ſhould be required, theſe will communicate to them a ſufficient power to proceed with, and they may in a ſhort time, by the ſame method, be brought to their full ſtrength.

MAGNIFYING, in philoſophy, the making of objects appear larger than they would otherwiſe do; whence convex lenſes, which have the power of doing this, are called magnifying glaſſes; and of ſuch glaſſes are microſcopes conſtructed. See LENS and MICROSCOPE.

MAGNITUDE, whatever is made up of parts locally extended, or that hath ſeveral dimenſions; as a line, ſurface, ſolid, &c. See the article LINE, &c.

The apparent magnitude of a body is that meaſured by the viſual angle, formed by rays drawn from its extremes to the center of the eye; ſo that whatever things are ſeen under the ſame or equal angles, appear equal; and *vice verſa*.

MAGNOLIA, the laurel-leaved tulip-tree, in botany, a genus of plants, the corolla of which conſiſts of nine oblong, hollow, and obtuſe petals, narroweſt towards the baſe: the fruit is an oval ſtrobilus, compoſed of compreſſed, roundiſh, acute, and cluſtered capſules, which are unilocular, and contain a ſingle kidney-ſhaped ſeed.

Could this beautiful tree be ſo far naturalized as to endure the cold of our ſevere winters, it would make one of the greateſt ornaments of our gardens. It is propagated by ſeeds, which ſhould be procured from Carolina.

MAHOMETANS, thoſe who believe and practiſe the religion of Mahomet.

The fundamental poſition on which Mahomet erected the ſuperſtructure of his religion, was, that there has been from the beginning of the world but one true orthodox belief, which conſiſts in acknowledging one only true God, and obeying ſuch of his meſſengers and prophets as he has from time to time ſent into the world, to reveal his will to mankind. Upon this foundation he ſet up for a prophet to extirpate idolatry, which was the religion of the Arabs, hs countrymen, and to reform the other abuſes crept into religion. The whole ſubſtance of his doctrine he therefore comprehended in theſe two principal articles of faith, "There is but one God, and Mahomet is his prophet;" in conſequence of which laſt article,

ticle, all ſuch ordinances and inſtitutions as he thought fit to eſtabliſh, were to be received as obligatory and of divine authority.

The Mahometans divide their religion into two general parts, faith and practice; of which the firſt is divided into ſix diſtinct branches; belief in God, in his angels, in his Scriptures, in his prophets, in the reſurrection and final judgment, and in God's abſolute decrees. The points relating to practice are, prayer, with waſhings, &c. alms, faſting, pilgrimage to Mecca, and circumciſion. In regard to theſe practical points, Mahomet, it is ſaid, declared, that the practice of religion is founded upon cleanlineſs, which is one half of faith and the key of prayer. Alms-giving is thought to be ſo pleaſing in the ſight of God, that the caliph Omar Ebn Abdalaziz uſed to ſay, prayer carries us half way to God; faſting brings us to the door of his palace; and alms procure us admiſſion: and Mahomet himſelf uſed to ſay of faſting, that it was the gate of religion; and the odour of the mouth of him who faſteth is more grateful to God, than that of muſk. Beſides theſe they have ſome negative precepts and inſtitutions of the koran, in which ſeveral things are prohibited, as uſury, the drinking of wine, all games that depend upon chance, the eating of blood and ſwine's fleſh, and whatever dies of itſelf, is ſtrangled, or is killed by a blow or by another beaſt. Theſe doctrines and practices Mahomet eſtabliſhed by the ſword, by preaching, and by the alkoran or koran, which contains the principles of his religion; and he and his followers met with ſuch ſucceſs, as in a few years to ſubdue half the known world. See ALCORAN.

MAIDEN, an inſtrument uſed in Scotland for beheading criminals.

This is a broad piece of iron about a foot ſquare, very ſharp on the lower part, and loaded above with a very heavy weight of lead. At the time of execution it is pulled up to the top of a narrow wooden frame, about ten feet high, and as broad as the engine, with mouldings on each ſide for the maiden to ſlide in. A convenience is made about four feet from the ground, for the priſoner to lay his neck; and there is a kind of bar ſo faſtened as to keep him from ſtirring. The priſoner being thus ſecured, and the ſign given, the maiden is let looſe, which in a moment ſeparates his head from his body.

MAIDEN-ASSIZE, an aſſize in which no perſon is condemned to die.

MAJESTY, a title given to kings, which frequently ſerves as a term of diſtinction.

MAIL, or *Coat of* MAIL, a piece of defenſive armour for the body, made of ſmall iron rings, interwoven in the manner of a net.

MAIM, MAIHEM, or MAYHEM, in law, a wound by which a perſon loſes the uſe of a member that might have been a defence to him.

MAIN, in the ſea-language, chief, principal, as the main-maſt, main-yard, main-ſail, main-hatchway, &c.

MAIN alſo implies ſome continent or great land, as oppoſed to iſland: We ſteered between the iſland and the main.

For the articles	MAIN-BOWLINES	See	BOWLINES
	MAIN-BRACES		BRACES
	MAIN-HATCHWAY		HATCHWAY
	MAIN-JEARS		JEARS
	MAIN-LIFTS		LIFTS
	MAIN-MAST		MAST
	MAIN-SAIL		SAIL
	MAIN-SHROUDS		SHROUDS
	MAIN-TYE		TYE
	MAIN-YARD		YARD.

MAINPRISE, in law, is the receiving a perſon into friendly cuſtody, who might otherwiſe be committed to priſon, on ſecurity given that he ſhall be forth-coming at a certain time and place appointed. There is a difference between bail and mainpriſe, for a perſon mainpriſed is ſaid to be at large from the day of his being mainpriſed, till the day of his appearance, and is not liable to be confined by his ſureties: but when a perſon is let to bail by a judge, &c. till a certain day, he is in law always accounted in the ward of his bail during the time, and they may, if they pleaſe, keep him in priſon.

MAINTENANCE, in law, is an unlawful maintaining or ſupporting a ſuit between others, by ſtirring up quarrels, or interfering in a cauſe in which the perſon has no concern.

MAJOR, in the art of war, the name of ſeveral officers of very different ranks and functions; as, 1. Major-general, the next officer to the lieutenant-general; his chief buſineſs is to receive the orders from the general, or in his abſence from the lieutenant-general of the day, which he is to diſtribute to the brigade-majors, with whom he is to regulate the guards, convoys, and detachments. When there are two attacks at a ſiege, he commands that on the left. He ought to be well acquainted with the ſtrength of each brigade, of each regiment in particular, and to have a liſt of all the field officers. In ſhort, he is in the army, what a major is in a regiment. He is allowed an aid de camp, and has a ſerjeant and fifteen men for his guard. 2. Major of a brigade, the officer who receives the orders from the major-general, and afterwards delivers them to the adjutants of the regiments at the head of the brigade; where he takes and marches the detachments, &c. to the general rendezvous. He ought to be an expert captain, to know the ſtate and condition of the brigade, and keep a roll of the colonels, lieutenant-colonels, majors, and adjutants. 3. Major of a regiment, the next officer to the lieutenant-colonel, generally promoted from the eldeſt captain. He is to take care that the regiment be well exerciſed, to ſee it march in good order, and to rally it in caſe of its being broke. He is the only officer among the foot that is allowed to be on horſeback in time of action, that he may the more readily execute the colonel's orders, either in advancing or drawing off the regiment. 4. Major of a regiment of horſe, is the firſt captain, who commands in the abſence of the colonel. 5. Town-major, the third officer in a garriſon, being next to the deputy-governor. He ought to underſtand fortification, and hath charge of the guards, rounds, patrols, &c. His buſineſs is alſo to take care that the ſoldiers arms are in good order; he likewiſe orders the gates to be opened and ſhut, and gives the governor an account of all that paſſes within the place.

There are alſo aids-major, drums-major, &c. ſo called from their preheminence above others of the ſame denomination.

MAJOR, in logic, the firſt propoſition of a ſyllogiſm. See the article SYLLOGISM.

MAJOR and MINOR, in muſic, ſignify imperfect concords, which differ from each other by a ſemi-tone minor. See CONCORD.

MAJOR-DOMO, an appellation formerly given to the ſteward or maſter of the king's houſhold.

MAJORANA, marjoram, in botany, a low plant, with ſlender, ſquare, branched, woody ſtalks, and little, oval, ſomewhat downy leaves, ſet in pairs: on the tops grow ſcaly heads of ſmall whitiſh labiated flowers, whoſe upper lip is erect and cloven, the lower divided into three ſegments. It is ſown annually in gardens, for culinary as well as medicinal uſes: the ſeeds, which rarely come to perfection in England, are procured from the ſouth of France, where the plant is ſaid to be indigenous.

The leaves and tops of marjoram have a pleaſant ſmell, and a moderately warm aromatic bitteriſh taſte. Infuſions of them in water, in colour browniſh, ſmell pretty ſtrongly, and taſte weakly and unpleaſantly of the herb: the blackiſh green tinctures, made in rectified ſpirit, have leſs ſmell, but a ſtronger and more agreeable taſte. In diſtillation with water, an eſſential oil is obtained, amounting, as Hoffman obſerves, to about one ounce from ſixty-four of the leaves ſlightly dried; when carefully drawn, of a pale yellow colour; by age, or too haſty fire in the diſtillation, contracting a reddiſh hue; of a very hot penetrating taſte, and in ſmell not near ſo agreeable as the marjoram itſelf: the remaining decoction, thus diveſted of the volatile aromatic matter, is weakly, but unpleaſantly, bitteriſh and auſtere. Great part of the aromatic matter of the herb riſes alſo in the inſpiſſation of the ſpirituous tincture, and impregnates the diſtilled ſpirit: the remaining extract is ſtronger in taſte than that made with water, its quantity being leſs, but has not much of the warmth or flavour of the marjoram.

This plant has been chiefly recommended in diſorders of

of the head and nerves, in uterine obſtructions and mucous diſcharges proceeding from what is called a cold cauſe, that is, from a laxity and debility of the ſolids, and a ſluggiſh ſtate of the juices, and in the humoural aſthmas and catarrhs of old people. The powder of the leaves, thin diſtilled water, and the eſſential oil properly diluted, are agreeable errhines, and accounted particularly uſeful in pituitous obſtructions of the noſtrils, and diſorders of the olfactory organs.

MAJORITY, the greater number of perſons.

MAIZE, a ſpecies of grain ſo generally uſed for food in America, that it has obtained the name of Indian corn.

The ſize of its ear differs greatly, according to the fertility of the ſoil, and the warmth of the climate in which it is cultivated; but at a medium, it is about a ſpan long, and commonly has eight or more rows of grain, each of which uſually contains upwards of thirty ſeeds, of various colours, as red, white, yellow, blue, olive, greeniſh, blackiſh, ſpeckled, ſtriped, &c. ſometimes in the ſame field, and the ſame ear: but the white and yellow are the moſt common: nor does this diverſity of colours ever reach beyond the outſide of the grain, the flour of which always is white, with a little tinge of yellow. Theſe ſeeds, which are as big as large peas, are round at their outer ſurface, very ſmooth, and ſet extremely cloſe, in ſtraight lines. The ear is cloathed and armed with ſeveral ſtrong thick huſks, which defend it not only from unſeaſonable rains and the cold of the night, for it does not ripen fully in ſome places, till towards the latter end of September, but alſo from crows and other birds, which, being allured by the ſweetneſs of the grain before it hardens, flock to it in great numbers, ſuck through the top of the outer covering, and devour as far as they can reach. In the northern colonies, the ſtalk of this plant, which contains a remarkably ſweet pith, and is jointed like a cane, does not grow near ſo high as in the ſouthern parts. It has long leaves, almoſt like flags, at every joint, and at the top a bunch of flowers, of various colours, highly pleaſing to the eye. The northern Indians, far up in the country, have a ſpecies of this grain, called Mohawk's corn, which never grows high, and, though planted in June, ripens in due ſeaſon. The general time of planting it is between the middle of March and the beginning of June, or, more particularly, from the middle of April to the middle of May.

This plant is ſeldom cultivated in England for uſe, though it might probably turn to good account, as was lately experienced by a gentleman in Lincolnſhire, who planted this corn in an open field, where it ripened perfectly, and yielded an abundant crop. Large quantities of it are raiſed in Aſia and Africa, in ſeveral parts of France, in Italy, Germany, and North America.

The Engliſh in North America plough the ground thoroughly before the grain is planted. They ſeldom, if ever, dung the whole face of the field, but ſometimes put a little dung in each hill of corn, if they think the ground requires it.

In order to plant the corn, they make trenches or furrows, with a plough, acroſs the field, at certain diſtances from each other, and croſs theſe with others of the ſame diſtance, which divide the field into ſquares; and where the trenches interſect, the grain is put in, and covered. Three or four grains are commonly planted for each hill. The intermediate ground is afterwards ploughed at leiſure, as the plants grow, and want more looſe earth for the roots to ſpread in. The hills are made at the time of weeding; ſome looſe earth being then hoed up over the roots, and round the ſtems or ſtalks of the corn.

The corn is planted at different diſtances in different places. In the northern colonies the maize grows low, ſeldom exceeding four or five feet in height; and the leaves being proportionably ſmall, the plants do not require ſo much ground as in the ſouthern colonies, where they frequently riſe to fourteen or fifteen feet. The ſpace generally allowed for the loweſt plants is three feet, and for the higheſt, five or ſix.

The pamcles, or toſſils, contain the *farina ſecundans* of the plant, and therefore ſhould not be cut off till the grain in the ear is filled. If the toſſils of a whole field ſhould be cut off before that time, there would be no grain at all in the ears. This has been proved by experiment.

In the more ſouthern colonies, where hay is ſcarce, and the leaves of this corn are very large, they cut them off for fodder; but in the northern colonies, where there is plenty of hay, and the leaves of the corn are ſmall, they generally neglect cutting off the toſſils, and ſtripping off the leaves. They are left on the ſtalks, and the cattle being turned into the fields, after the corn is gathered in, eat what they like of them; but they are not eſteemed ſo good as what has been cut in ſeaſon.

An eaſy way of taking the grain out of the ears, is to rub one againſt another, holding one in each hand.

When the ears are ſtripped off their huſks, they are reckoned in the beſt ſtate for preſervation; much better than when the grain is rubbed off from the ear: for then, ſay they, inſects can get at the ſoft part of the grain, and eat into it; which they cannot do while the ſoft part is connected with the cob in the ear, and the hard flinty part of every grain turned outward, and the grains cloſe to each other.

The manner of uſing this corn in America is various. It has this advantage over wheat, that ſubſtance may be drawn from your corn-fields long before the general harveſt; for the green ears roaſted are delicate food; and as the corn ripens and grows harder, the ears boiled are good eating with butter and ſalt. When it is ripe, the corn parched and ground into meal, is the hunting and war proviſion of the Indians; being light to carry, and affording good nouriſhment. They mix a little of it with water, and it needs no other cooking, having already paſſed the fire in the parching. The grain ſoaked in water, will part with its ſkin when beat in a large morter with a wooden peſtle; then it is boiled and eaten with milk. Being pounded coarſely, dry, it alſo boiled and eaten as rice. Bag puddings, and baked puddings made of it properly, are very good. The meal is alſo boiled with water, to make what they call a haſty pudding, which they eat with butter and ſugar, or with milk. This haſty-pudding, or boiled meal, being mixed with twice as much dry wheat flour, and worked into loaves, makes much better and pleaſanter bread than flour alone.

MAKING-UP, among diſtillers, the reducing ſpirits to a certain ſtandard of ſtrength, uſually called proof, by the admixture of water; which ſhould be either ſoft and clear river-water, or ſpring-water rendered ſoft by diſtillation.

MALACHI, or *the Prophecy of* MALACHI, a canonical book of the Old Teſtament, and the laſt of the twelve prophets. Malachi propheſied about three hundred years before Chriſt, reproving the Jews for their wickedneſs after their return from Babylon, charging them with rebellion, ſacrilege, adultery, prophaneneſs, and infidelity, and condemning the prieſts for being ſcandalouſly careleſs in their miniſtry; at the ſame time not forgetting to encourage the pious few, who, in that corrupt age, maintained their integrity. This prophet diſtinctly points at the Meſſiah, who was ſuddenly to come to his temple, and to be introduced by Elijah the prophet, that is, by John the Baptiſt, who came in the ſpirit and power of Elias or Elijah.

MALACHITES, or MOLOCHITES, in natural hiſtory, &c. a ſpecies of jaſper, ſuppoſed to be poſſeſſed of amuletic virtues. See JASPER and AMULET.

MALACIA, *μαλακια*, in medicine, is a languiſhing diſorder incident to pregnant women, in which they long ſometimes for one kind of food, and ſometimes for another, and eat it with an extraordinary greedineſs. When women labouring under this diſorder begin to abſtain from the improper and abſurd things they were fond of, and with leſs reluctance uſe laudable and wholeſome aliments, it is an infallible ſign of a beginning cure and approaching health. Pregnant women are generally freed from the malacia, about the fourth month; but if it continues longer it is dangerous, becauſe the peccant humours are deeply rooted. For the cure of this diſorder, in pregnant women, but few medicines are recommended for fear of abortion: however, gentle medicines may be uſed for evacuating and corroborating the ſtomach. In young women

women labouring under a chlorosis, this distemper is cured by the same medicines that are proper for removing the chlorosis. See the article CHLOROSIS.

MALACOPTERYGIOUS, among ichthyologists, an appellation given to one of the five orders of fishes, from their having the rays of their fins bony, but not pointed or sharp at the extremities, like those of acanthopterygious fishes, See the article FISH and ICHTHYOLOGY.

MALACOSTOMOUS FISHES, those destitute of teeth in the jaws, called in English leather-mouthed: as the tench, carp, bream, &c.

MALAGMA, a cataplasm. See the article CATAPLASM.

MALANDERS, in farriery, are cracks in the bend of a horse's knee, that discharge a sharp indigested matter; they are often the occasion of lameness, stiffness, and the horse's tumbling.

This distemper is cured by washing the parts with a lather of sope warmed, or old chamber-ley; and then applying over the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off: if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it.

Take of Æthiops mineral half an ounce; white vitriol one dram; soft green sope six ounces. Anoint with this often, but first clip away the hair, and clear the scabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre balls may be taken advantageously for a fortnight, or three weeks.

MALE, *Mas*, among zoologists, that sex of animals which has the parts of generation without the body. See the articles ANIMAL, SEX, and GENERATION.

The term male has also, from some similitude to that sex in animals, been applied to several inanimate things: thus we say, a male flower, a male screw, &c. See the articles FLOWER and SCREW.

MALICE, in law, is a premeditated design to do mischief to another.

MALIGNANT, among physicians, a term applied to diseases of a very dangerous nature, and generally infectious: such are the dysentery, hospital fever, &c. in their worst stages.

MALL, or SEA-MALL, in ornithology, the English name of the lesser gull, with a grey back and spotted neck, and about the size of the common tame pigeon.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer. See the articles DUCTILITY and METAL.

MALLEOLUS, in anatomy, a name given by anatomists to the inferior extremities of the tibia and fibula.

MALLET, a kind of large wooden hammer, used by artificers who work with a chissel, as sculptors, masons, and stonecutters, whose mallets are commonly round; and by joiners, carpenters, &c. who work with square-headed mallets.

Serving MALLET, among sailors, a mallet used in serving ropes. See the article SERVICE.

The use of the mallet is to bind the spun-yarn or other line very tight about the rope, to prevent it from being chafed by friction; two or three turns of the spun-yarn for this purpose are wound about the body of the mallet, and while one man passes the spun-yarn ball, another binds the turns of it on the rope, by turning the mallet round it, which draws it very tight.

Caulking MALLET, a mallet used by caulkers to drive oakum into the seams of a ship. See the article CAULKING.

MALLEUS, in anatomy, a bone of the ear, so called from its resemblance to a mallet, and in which is observed the head, the neck and handle, which is joined to the membrane of the tympanum. See EAR.

MALLOW, MALVA, in botany. See the article MALVA.

Vervain-MALLOW. See ALCEA.

MALMSEY, a rich kind of wine, so called, as being brought from Malvasia, in the Morea.

MALT is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short at the beginning of vegetation.

In making malt for barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a bright brown, or reddish colour. Then this water being drained away, the barley is removed from the steeping cistern to the floor, where it is thrown into what is called the wet couch; that is, an even heap, rising to the height of about two feet. In this wet couch, the capital part of the operation is performed; for here the barley spontaneously heats, and begins to grow, shooting out first the radicle, and if suffered to continue, then the plume, spire or blade. But the process is to be stopped short at the eruption of the radicle, otherwise the malt would be spoiled. In order to stop it, they spread the wet couch thin over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thicker each time. After this, it is again thrown into a large heap, and there suffered to grow sensibly hot to the hand, as it usually will in twenty or thirty hours time; then being spread again, and cooled, it is thrown upon the kiln, to be dried crisp without scorching,

This is the general process of malting, in which almost every maltster has his secret, or particular way of working. But to render the operation perfect, the following cautions must be observed: 1. That the barley be newly threshed, or at least newly winnowed. 2. That it be not mixed, or made up of different sorts. 3. That it be not over steeped in the cistern, or so long as to make it soft. 4. That it be well drained. 5. That it be carefully looked after in the wet couch, so as to stop the first tendency of the blade to shooting. 6. Another caution is, to turn the wet couch inside outermost, if the barley comes, and shoots more in the middle of the heap than on the sides. 7. To keep it duly turning, after it is out of the wet couch. 8. To give it the proper heating in the dry heap. 9. To dry and crisp it thoroughly upon the kiln, but without a fierce fire, so as to be several days in drying a kiln of pale malt. And if these directions be carefully observed, the malt will always be good.

The method of malting Indian corn or Virginia-wheat, is much less laborious. For if this corn be buried two or three inches deep in the earth, and covered with the loose mould, dug up to make room for it, in ten or twelve days time the corn will sprout and appear like a green field; at which time being taken up, and washed or fanned from its dirt, it is immediately committed to the kiln, and by this means it becomes good malt. It is observable of this corn, that both its root and blade must shoot to a considerable length, before it will make malt; and perhaps this is the case in all large bodied grain.

The importation of malt from beyond the seas is prohibited: and on its being exported, it is not only freed from paying the excise of 6 d. a bushel, but a bounty is allowed by act of parliament, for which see the article CORN.

Malt-liquors have different names, and different virtues, from the different methods of preparing the malt, whence they are distinguished into pale and brown; and from the various methods taken in brewing the liquors, whence they are divided into ale and beer, strong and small, new and old. See BREWING.

The colour of the liquor, and many of its effects, depend on the manner of drying the malt it is brewed with; that which has the palest tinge, is made with malt but slenderly dried; whereas that which is high coloured, is made with malt that is high dried, or roasted, as it were, in comparison of the other; and amber ale is made of a mixture of both. Another difference in the preparations of malt-liquors consists in the larger quantity of hops in beer, and the smaller in ale; for hops add something of an alkaline nature to the liquor, and not only render it more easy of digestion and secretion in the body, but while it is in the liquor, prevent its running into such cohesions as would make it ropy, vapid, and sour. For this reason Dr. Quincy is of opinion, that for one constitution injured by beer, there are numbers spoiled by ale, which is apt to stuff the vessels with slime and viscidity,

dity, to make the body unwieldy and corpulent, and to pave the way for cachexies, the jaundice, aſthmas, and the dropſy. The different degrees of ſtrength in malt-liquors alſo makes them produce different effects. The ſtronger they are, the more viſcid parts they carry into the blood: they are therefore in general the more wholeſome for being ſmall: that is, of ſuch a ſtrength as to carry ſome degree of warmth into the ſtomach, but not ſo as to prevent their being proper diluters of our neceſſary food. Indeed people of robuſt conſtitutions, who labour very hard, may diſpenſe with reaſonable quantities of the ſtrongeſt; eſpecially as their food is frequently poor and ſlender enough, the deficiencies of which this ſupplies; and their continual exerciſe and ſtrength of body digeſts and breaks the viſcidities of the drink into convenient nouriſhment: though in perſons of another habit and way of living, they would only produce obſtructions and ill humours. As to the age of theſe liquors, it has ſomewhat the ſame effect as hops, for thoſe that are longeſt kept, are certainly leaſt viſcid: for age, by degrees, breaks their viſcid parts, and by rendering them ſmaller, makes them fitter for ſecretion.

MALT-SPIRITS. See the articles DISTILLERY and SPIRITS.

Knights of MALTA, otherwiſe called *Hoſpitallers of St. John of Jeruſalem*, a religious military order, whoſe reſidence is in the iſland of Malta. The order conſiſts of three eſtates, the knights, chaplains, and ſervants at arms: there are alſo prieſts who officiate in the churches, friar-ſervants, who aſſiſt at the offices, and donnes or demicroſſes; but theſe are not reckoned conſtituent parts of the body: the government of the order is mixt, being partly monarchical, and partly ariſtocratical: the grand maſter is ſovereign. The knights formerly conſiſted of eight different languages, but now only ſeven, the Engliſh having withdrawn themſelves. None are admitted into this order but ſuch as are of noble birth: the knights are of two ſorts, thoſe who have a right to be candidates for the dignity of grand maſter, called grand croſſes, and thoſe who are only knights aſſiſtants: they never marry, yet have continued from 1090 to the preſent time. The knights are received into this order either by undergoing the trials preſcribed by ſtatutes, or by diſpenſation.

MALTHA, in antiquity, a kind of cement, of which there were two ſorts, native and factitious; one of the latter ſort, much in uſe, conſiſted of pitch, wax, plaſter, and greaſe. Another kind uſed by the Romans in their aqueducts, was made of lime ſlacked in wine, incorporated with melted pitch, and freſh figs. Natural maltha is a kind of bitumen, wherewith the Aſiatics plaſter their walls; and which being once ſet on fire, water makes it burn more fiercely.

MALVA, common mallow, in botany, a plant with firm branched ſtalks, and roundiſh, notched leaves, ſet alternately on long pedicles: in their boſoms come forth bell-ſhaped monopetalous flowers, deeply divided into five heart-ſhaped ſections of a pale purpliſh or whitiſh colour, variegated with deeper ſtreaks, followed by a number of capſules ſet in form of a flat diſk, and containing each a kidney-ſhaped ſeed: the root is long, ſlender, and whitiſh. It is perennial, common in uncultivated grounds, and found in flower throughout the ſummer.

The leaves and flowers of the mallow are in taſte mucilaginous, and of no remarkable ſmell. The leaves were formerly of ſome eſteem, as an emollient or laxative dietetic, in dry conſtipated habits, in the warmer climates: at preſent, infuſions or decoctions of the leaves and flowers, and a conſerve made by beating the freſh flowers with thrice their weight of fine ſugar, are ſometimes directed in dyſuries, heat and ſharpneſs of urine, and other like complaints; but the principal uſe of the herb is in emollient clyſters, cataplaſms, and fomentations. The roots have been recommended in diſorders of the breaſt, and though now diſregarded may perhaps deſerve ſome notice: they have a ſoft ſweet taſte, without any particular flavour, approaching in ſome degree to that of liquorice: an extract made from them by rectified ſpirit of wine is of a great ſweetneſs.

MALUS, the apple-tree, in botany, is, according to Linnæus, a ſpecies of the pyrus. See APPLE and PYRUS.

MAMALUKES, the name of a dynaſty that reigned in Egypt.

The Mamalukes were originally Turkiſh and Circaſſian ſlaves, bought of the Tartars by Melicſaleh, to the number of a thouſand, whom he bred up to arms, and raiſed ſome to the principal offices of the empire. They killed ſultan Moadam, to whom they ſucceeded.

Others ſay, that the Mamalukes were ordinarily choſen from among the Chriſtian ſlaves, and that they were the ſame thing in a great meaſure with the Janiſſaries among the Turks. They never married. They firſt are ſaid to have been brought from Circaſſia, and ſome have ſuppoſed that they began to reign about the year 869.

MAMMÆ, the breaſts, in anatomy, two eminences, more or leſs round, ſituated in the anterior, and a little towards the lateral parts of the thorax; their middle part lying almoſt oppoſite to the bony extremity of the ſixth rib on each ſide.

In children of both ſexes, and in males of all ages, they are commonly no more than cutaneous tubercles, or ſoft verrucæ of a reddiſh colour, called papillæ, or nipples; each of them being ſurrounded by a ſmall, thin, and pretty broad circle, more or leſs of a browniſh colour, and an uneven ſurface termed areola.

In females, when come to the age of puberty, which is ſometimes ſooner, ſometimes later, a third part is joined to the two former, which is a convex protuberance more or leſs round, of about five or ſix fingers in breadth, the papilla and areola being ſituated near the middle of the convex ſurface. This is what is properly termed the mamma, and it may be called the body of the breaſt, when compared with the other two parts. It increaſes with age, and is very large in women with child, and in thoſe that give ſuck. In old age it decreaſes and becomes flabby, loſing its natural conſiſtence and ſolidity.

The body of the breaſt is partly glandular, and partly made up of fat; or it is a glandular ſubſtance, mixed with portions of the membrana adipoſa, the cellulous pellicles of which ſupport a great many blood-veſſels, lymphatics, and ſerous or lactiferous ducts, together with ſmall glandular moleculæ, which depend on the former; all of them being cloſely ſurrounded by two membranes, continued from the pelliculæ.

The innermoſt of theſe two membranes, which is, in a manner, the baſis of the body of the mamma, is thick and almoſt flat, adhering to the muſculus pectoralis major. The ſecond or external membrane is thinner, forming a particular integument for the body of the breaſt, more or leſs convex, and adhering cloſely to the ſkin.

The corpus adipoſum of the breaſt in particular is a ſpongy cluſter, more or leſs interlarded with fat, or a collection of membranous pelliculæ, which, by the particular diſpoſition of their outſides, form a kind of membrane in ſhape of a bag, in which all the reſt of the corpus adipoſum is contained. The anterior or outer portion of this bag, or that which touches the ſkin, is very thin; but that ſide next the pectoralis major is thick.

The glandular body contains a white maſs, which is merely a collection of membranous ducts, narrow at their origin, broad in the middle, and which contract again as they approach the papillæ, near which they form a kind of circle of communication. They are called ductus lactiferi.

The areola is formed by the ſkin; the inner ſurface of which ſuſtains a great number of ſmall glandular moleculæ, of that kind which Morgagni calls glandulæ ſebaceæ. They appear very plainly all over the areola, even on the outſide, where they form little flat eminences, at different diſtances, quite round the circle.

Theſe tubercles are perforated by ſmall holes, through which a kind of ſebaceous or cheeſy matter, more or leſs liquid, may be ſqueezed out. Sometimes this is a ſerous liquor, ſometimes a milky ſerum, and ſometimes pure milk, eſpecially in nurſes; and I have ſeen both ſerous and milky drops come out at the ſame time.

From thence I am inclined to think, that theſe holes communicate with the lactiferous ducts, and that the tubercles are a kind of auxiliary papillæ added to the true ones. The different liquors that may be ſqueezed from

from the ſame glandular body, give alſo room to think, that the holes in them communicate by their extremities with ſeveral other ſmall holes. The tubercle in the center of the areola is termed papilla, or the nipple: it is of different ſizes, in different ages and conſtitutions, and in the different conditions of females in particular. In women with child, or who give ſuck, it is pretty large, and generally longer and higher than it is thick or broad; and when it happens to be ſhort, it cauſes great uneaſineſs to the child.

The texture of the nipple is ſpongy, elaſtic, and liable to divers changes of conſiſtence. It ſeems to be made up principally of ligamentary faſciculi, the extremities of which form the baſis and apex of the nipple: theſe faſciculi appear to be gently folded or curled, through their whole length; and if, by drawing the fibres out, theſe folds be deſtroyed, they return again as ſoon as that action ceaſes.

Between theſe faſciculi lie ſeven or eight particular tubes, at ſmall diſtances from each other, and all in the ſame direction; theſe tubes end at the baſis of the papilla, in the irregular circle of communication of the lactiferous ducts, and at the apex, in the ſame number of almoſt imperceptible holes; and as they are cloſely united to the elaſtic faſciculi, they are folded in the ſame manner with them.

The body of the papilla is covered by a thin cutaneous production, and by the epidermis; its outer ſurface is uneven, being full of ſmall wrinkles; among which thoſe near the circumference of the nipple ſeem to have a tranſverſe or annular diſpoſition, which, however, is not uniform.

This diſpoſition ſeems to be owing to the elaſtic folds; and from this ſimple ſtructure it is eaſy to explain how infants in ſucking the nipple, and women in drawing the teats of cows, bring out the milk. For the excretory tubes, being wrinkled in the ſame manner as the faſciculi, do by theſe folds, as by ſo many valves, hinder the milk contained in the ducts from flowing out; but when the nipple is elongated the tubes loſe their folds, and the paſſage becomes ſtraight. Beſides this, when they are drawn with a conſiderable force, the whole body of the breaſt is increaſed in length, and contracted in breadth, and thereby the milk is preſſed into the open tubes; and thus, by barely preſſing the body of the breaſt, the milk may be forced toward the nipple, and even through the tubes.

The arteries and veins diſtributed through the mammæ are ramifications of the arteriæ and venæ mammariæ, of which one kind comes from the ſubclaviæ, and are called mammariæ internæ; the other from the axillares, called mammariæ externæ.

Theſe veſſels communicate with each other, with thoſe near them, and with the vaſa epigaſtrica. The nerves come principally from the coſtales, and by means of theſe communicate with the great nervi ſympathetici.

The uſe of the breaſts, in the nouriſhment of children, is well known to the world: but it is not certainly known what the papillæ and areolæ in men can be deſigned for. Milk has been obſerved in them in children of both ſexes. *Winſlow.*

MAMMIFORM, in anatomy, a name given to apophyſes of the bone in the back part of the ſcull, ſo called from their reſembling a breaſt.

MAMMILLARY, MAMMILLARIS, in anatomy, an epithet given to two little protuberances, ſomewhat reſembling the nipples of the breaſt, found under the four ventricles of the brain, and ſuppoſed to be the organs of ſmelling. Theſe are called apophyſes mammillares. There is alſo a muſcle called mammillaris, or maſtoides, ſerving to ſtoop the head.

MAMMOTH's TEETH, in natural hiſtory, certain large foſſile teeth, found in great plenty in Ruſſia, and ſuppoſed to have belonged to elephants.

MAN, *Homo*, in zoology, is juſtly ranked at the head of the animal part of the creation; making a diſtinct genus of that order of quadrupeds, which Linnæus calls anthropomorpha, from their reſemblance to the human form.

The ſame author diſtinguiſhes the race of mankind, according to their different colours, into the Europeans, or white men; the Americans, or copper-coloured men: the Aſiatics, or tawny-coloured men: and thoſe of Africa, or blacks.

Noſce te ipſum, know thyſelf, is a precept worthy of the law-giver of Athens, the ancient ſeat of polite literature; an important branch of knowledge, which may be reduced to the following heads. 1. In a religious view, *theologicè*, that you was created with an immortal ſoul, after the image of God. 2. In a moral ſenſe, *moraliter*, that you alone was bleſſed with a rational ſoul, to be employed to the praiſe of the Creator. 3. With reſpect to the other works of the creation, *naturaliter*, that you are conſtituted their lord, for whoſe uſe they were made. 4. In a phyſiological ſenſe, *phyſiologicè*, the moſt perfect and amazing fabric of your body. 5. With regard to diet, *diætetice*, what things are uſeful, and what hurtful, in this reſpect. 6. In a pathological ſenſe, *pathologicè*, how frail you are, and how ſubject to a thouſand calamities.

Theſe are the heads, which, according to Linnæus, comprehend the knowlege of man, conſidered as an individual; a branch of knowledge ſo eſſential to the human race, that, without it, he ſeems to doubt whether any other characters be ſufficient to entitle one to be ranked among mankind: for he adds, *Hæc ſi noveris*, HOMO *es, et a reliquis animalibus diſtinctiſſimum genus.*

MANATI, in zoology, an animal called by Linnæus thrichechus. See THRICHECHUS.

MANDAMUS, in law, a writ that iſſues out of the King's Bench, ſent to a corporation, commanding them to admit or reſtore a perſon to his office.

MANDARINS, a name given to the magiſtrates and governors of provinces in China, who are choſen out of the moſt learned men, and whoſe government is always at a great diſtance from the place of their birth. Mandarin is alſo a name given by the Chineſe to the learned language of the country; for beſides the language peculiar to every province, there is one common to all the learned in the empire, which is in China what Latin is in Europe; this is called the Mandarin tongue, or the language of the court.

MANDATE, in law, a judicial commandment to do ſomething.

MANDATE, in the canon-law, a reſcript of the pope, commanding an ordinary collator to put the perſon therein named in poſſeſſion of the firſt vacant benefice in his collation.

MANDREL, a kind of wooden pulley, making a member of the turner's lathe, of which there are ſeveral kinds, as the flat mandrels, which have three or more little pegs or points near the verge, and are uſed for turning flat boards on; the pin mandrels are thoſe which have a long wooden ſhank to fit into a large hole made in the work to be turned; hollow mandrels are thoſe hollow of themſelves, and uſed for turning hollow work; ſcrew mandrels for turning ſcrews, &c.

MANE, the hair hanging down from a horſe's neck, which ſhould be long, thin, and fine; and if frizzled, ſo much the better.

MANEGE, or MANAGE, the exerciſe of riding the great horſe, or the ground ſet apart for that purpoſe; which is ſometimes covered, for continuing the exerciſe in bad weather; and ſometimes open, in order to give more liberty and freedom both to the horſeman and horſe.

One way or other, we always ſuppoſe a center in the middle of the manege-ground, for regulating the rounds and volts. Sometimes this center is diſtinguiſhed by a pillar fixed in it, to which they tie the horſe when he begins to learn: upon the ſide of the manege other pillars are placed, two by two, in order to teach horſes to raiſe the fore quarters, by tying them with ropes. See PILLAR.

MANES, in the pagan ſyſtem of theology, a general name for the infernal deities, or gods of hell.

The ancients comprehended under manes not only Pluto, Proſerpine, and Minos, but the ſouls likewiſe of the deceaſed were taken into the number, and eſteemed gods of hell. It was uſual to erect altars and offer libations to the manes of deceaſed friends and relations.

MANGER, in the ſea-language, a ſmall apartment in the fore-part of a ſhip, which is fenced on the after-part by

by a ſort of bulk-head or barrier; the uſe of which is to prevent the water which ruſhes in at the hawſe-holes, or the holes thro, which the cable goes, from running on the lower decks, which would render them extremely uncomfortable to the men, who eat and ſleep there. As ſoon as the water enters at the hawſe-holes, which is always the caſe when the ſhip pitches deep forward, it is conveyed away again through the ſide into the ſea by ſeveral ſmall pipes or channels, called ſcuppers. See the article SCUPPERS.

MANGO *Tree*, in botany, the name of a vaſt tree, forty feet in height, and eighteen in thickneſs, and ſpreads its numerous branches all around at a great diſtance, being always green, and bearing fruit once or twice a year, from ſix or ſeven years old to an hundred. It is propagated by inſition, or ſowing the ſeed, in Malabar, Goa, Bengal, Pegu, and many other countries in the Eaſt-Indies.

The fruit is of a round oblong figure, flat, ſlightly ſinuated, or hollowed at the ſides, and ſhaped much like a kidney, bigger than a gooſe egg, ſmooth, ſhining, firſt green ſpeckled with white, then inclining to yellow, and at laſt of a gold-colour: it has a yellowiſh and ſucculent pulp, not unlike that of a peach; or rather a plum, firſt acid, then acido-dulcid, and pleaſant to the taſte. Within the pulp is contained an oblong, compreſſed, and languanous ſtone, thin, yet very hard and tenacious, and including a callous oblong kernel, very like an oblong almond, and of the ſame bigneſs, and of a bitteriſh, though not unpleaſant taſte.

There are various ſorts of this fruit, as there are of our apples and pears, which are very different, according to the countries where they grow: that ſpecies which is without a ſtone, and is very grateful to the palate, ſeems to us only a variety, or a degenerate fruit. The fruit is cut into ſlices, and eaten either without wine, or macerated in wine; it is alſo candied, in order to its preſervation. Sometimes they open it with a knife, and fill up the middle with freſh ginger, garlic, muſtard, and ſalt, with oil or vinegar, that they may eat it with rice, or after the manner of pickled olives.

As to its temperament, this fruit is cold and moiſt, though the Indian phyſicians affirm the contrary. We make uſe of pickled mangoes, which are imported to us, as we do of pickled cucumbers, for ſauce to roaſted meat. The ſtones roaſted are ſaid to cure a looſeneſs, which Garcias found to be true. The wood of the tree, with cinders, is uſed for burning the carcaſes of the pagans, as being conſecrated to this rite; whence it ſerves alſo for coffins, in which they repoſit their dead; it is but of a ſoft ſubſtance, and of ſhort duration.

The ſtalks ſupply the place of arequa or caunga, in the chewing of betel; the ſame, calcined and reduced to powder, take away warts. Of the tender leaves, with the bark of the avanacoe, that is, the ricinus, the ſeed of cummin and parpadogam, is made a decoction, which is highly beneficial in the cough, aſthma, and other affections of the thorax. The bark of the tree pulveriſed, and taken in chicken-broth, is an excellent diſſolvent of extravaſated and coagulated blood, occaſioned by a fall, in any part of the body. The juice of the bark, with the white of an egg, and a very little opium, taken inwardly, is a preſent remedy againſt the diarrhœa, dyſentery, and teneſmus. Of the gum of the tree, and the flowers of rice, with the addition of a ſmall quantity of opium and pepper, are prepared pills, which alſo cure all ſorts of fluxes of the belly. Of the flower of the dried kernels the natives have the art of preparing various kinds of food.

MANGANESE, MAGNESIA, in natural hiſtory, a poor kind of iron ore. See the article IRON.

It is a denſe, heavy ſubſtance in its fineſt pieces; being compoſed of a number of broad and thick ſtriæ irregularly laid together, and much reſembling thoſe of native antimony; in theſe maſſes it is ſometimes reddiſh, ſometimes of a dark grey, and ſometimes of a fine pale light grey, approaching to the colour of the fineſt poliſhed iron: but there is a leſs perfect kind in which the whole maſs ſeems only to conſiſt of a number of irregularly figured pieces, of a brittle and ſomewhat gloſſy ore, blended very looſely together.

Manganeſe is found in great abundance in the German and Swediſh mines, as alſo in France, Italy, and England; but ours is not equal in beauty or goodneſs to the German. It is recommended by authors as an aſtringent, and ordered to be given after calcination in hæmorrhages: but it is very improper for internal uſe. It is of great ſervice, however, to the glaſſmen, in clearing away the greeniſh colour from their white glaſs while in fuſion. See GLASS.

MANICHEES, in church hiſtory, a ſect of Chriſtian heretics in the third century, the followers of Manes, who made his appearance in the reign of the emperor Probus; pretending to be the Comforter, whom our Saviour promiſed to ſend into the world. He taught that there are two principles, or gods, coeternal and independant on each other, the one the author of all evil, and the other, of all good; a doctrine which he borrowed from the Perſian Magi. He held that our ſouls were made by the good principle, and our bodies by the evil one, and that the ſouls of his followers paſſed through the elements to the moon, and from thence to the ſun, where being purified, they then went to God, and became united with his eſſence; but as for the ſouls of other men, they either went to hell, or were united to other bodies. He alleged that Chriſt had his reſidence in the ſun, the Holy Ghoſt in the air, Wiſdom in the moon, and the Father in the abyſs of light. He is alſo charged with denying the reſurrection, and condemning marriage; with teaching that Chriſt was the ſerpent that tempted Eve; with forbidding the uſe of eggs, cheeſe, milk, and wine, as proceeding from the bad principle; with uſing a different kind of baptiſm from that of the church; with teaching that magiſtrates were not to be obeyed, and with condemning the moſt lawful wars.

MANICORDON, or MANICHORD, a muſical inſtrument in the form of a ſpinnet; the ſtrings of which, like thoſe of the clarichord, are covered with little pieces of cloth, to deaden, as well as to ſoften their ſound; whence it is alſo called the dumb ſpinnet. It is much uſed in nunneries, becauſe the nuns may play upon it without diſturbing that ſilence which they are obliged to obſerve in their cells.

MANIFESTO, a public declaration made by a prince in writing, ſhewing his intentions to begin a war, or other enterprize, with the motives that induce him to it, and the reaſons on which he founds his rights and pretenſions.

MANILLE, in commerce, a large braſs-ring in the form of a bracelet, either plain or engraven, flat or round.

Manilles are the principal commodities which the Europeans carry to the coaſt of Africa, and exchange with the natives for ſlaves. Theſe people wear them as ornaments on the ſmall of the leg, and on the thick part of the arm above the elbow.

MANIPULUS, in Roman antiquity, a body of infantry, conſiſting of two hundred men, and conſtituting the third part of a cohort. See COHORT.

Among phyſicians, the term Manipulus ſignifies a handful of herbs or leaves, or ſo much as a man can graſp in his hand at once; which quantity is frequently denoted by the abbreviature, M, or *m*.

MANNA, in the materia medica, a ſweet juice obtained from certain aſh trees in the ſouthern parts of Europe, particularly in Calabria and Sicily; exuding from the leaves, branches, or trunk of the tree, and either naturally concreted, or exſiccated and purified by art.

Juices of the ſame nature are collected, in the Eaſtern countries, from other trees and ſhrubs: and ſimilar exudations are ſometimes found on different kinds of trees in Europe, as particularly on the larch in the Briançonois in Dauphiny. How far the manna juices of different vegetables differ from one another, is not well known; but this much is certain, that one and the ſame tree affords mannas very conſiderably different, in their colour, in their taſte, and in their diſpoſition to aſſume a ſolid concrete form: that is, in their purity, or the greater or leſs admixture of oily or reſinous matter.

The beſt ſort of the officinal or Calabrian manna is in oblong pieces or flakes, moderately dry, friable, very light,

light, of a whitiſh or pale yellow colour, and in ſome degree tranſparent. The inferior kinds are moiſt, unctuous, and brown. Both ſorts are ſaid to be ſometimes counterfeited by compoſitions of ſugar, honey, and purgative materials: compoſitions of this kind, in a ſolid or dry form, may be diſtinguiſhed by their weight, compactneſs, and untranſparency; both the dry and moiſt compoſitions may be diſtinguiſhed by their taſte, which is ſenſibly different from that of true manna, and with greater certainty by their habitude to menſtrua.

This juice liquefies in a moiſt air, diſſolves readily in water, and by the aſſiſtance of heat, in rectified ſpirit alſo; the impurities only being left by both menſtrua. On inſpiſſating the watery ſolution, the manna is recovered of a much darker colour than at firſt. From the ſaturated ſpirituous ſolution, great part of it ſeparates as the liquor cools, concreting into a flaky maſs, of a ſnowy whiteneſs, and a very grateful ſweetneſs; the liquor remaining after the ſeparation of this pure ſweet part of the manna, leaves, on being inſpiſſated, an unctuous, dark-coloured, diſagreeable matter, in greater or leſs quantity, according as the manna made uſe of was leſs or more pure.

Manna, in doſes of an ounce and upwards, proves a gentle laxative: it operates in general with great mildneſs, ſo as to be ſafely given in inflammatory or acute diſtempers, where the ſtimulating purgatives have no place. It is particularly proper in ſtomachic coughs, or thoſe which have their origin in the ſtomach; the manna, by its ſweetneſs and unctuoſity, contributing to obtund as well as to evacuate the offending humours: in this intention it is ſometimes made into a linctus or lohoch, with equal quantities of oil of almonds and of ſyrup of violets. See LINCTUS.

In ſome conſtitutions, however, it acts unkindly, eſpecially if given in conſiderable quantity, occaſioning flatulencies, gripes, and diſtenſions of the belly; inconveniencies which may be generally obviated by a ſmall addition of ſome grateful aromatic.

MANNER, in painting, a habitude that a man acquires in the three principal parts of painting, the management of colours, lights, and ſhadows, which is either good or bad, according as the painter has practiſed more or leſs after the truth, with judgment and ſtudy. But the beſt painter is he who has no manner at all. The good or bad choice he makes is called goûte.

MANNERS, in poetry, the inclinations, genius, and humour, which the poet gives to his perſons, and whereby he diſtinguiſhes his characters. See the article CHARACTER.

MANOMETER, or MANOSCOPE, an inſtrument to ſhew or meaſure the alterations in the rarity or denſity of the air. The manometer differs from the barometer in this, that the latter only ſerves to meaſure the weight of the atmoſphere, or of the column of air over it; but the former the denſity of the air in which it is found, which denſity depends not only on the weight of the atmoſphere, but alſo on the action of heat and cold, &c. Authors, however, generally confound the two together, and Mr. Boyle himſelf gives us a very good manometer of his contrivance, under the title of a ſtatical barometer. See BAROMETER.

MANOR, an ancient royalty or lordſhip, formerly called a barony, conſiſting of demeſnes, ſervices, and a court-baron; and comprehending in it meſſuages, lands, meadow, paſture, wood, rents, an advowſon, &c. It may contain one or more villages, or hamlets, or only a great part of a village, &c.

A manor is a noble kind of fee, granted in part to tenants for certain ſervices to be performed, and partly reſerved to the uſe of the lord's family, with juriſdiction over the tenants, for their farms or eſtates.

There are capital manors or honours that have other manors under them; and alſo cuſtomary manors granted by copy of court roll, the lords of which have power to hold courts, and grant copies, &c.

MANSION, in law, is the chief dwelling-houſe of a lord within his fee, or the capital meſſuage or manor-houſe.

MANSLAUGHTER, generally termed homicide, is killing a perſon without premeditated malice.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almoſt ſix feet, generally caſed with tin, and ſet upon little wheels, ſo that in a ſiege, they may be driven before the pioneers, and ſerve as blinds to ſhelter them from the enemy's ſmall ſhot. See plate LXXXII. *fig* 7.

There are other ſorts of mantelets, covered on the top, of which the miners make uſe to approach the walls of a town or caſtle.

MANTLE, or MANTLE-TREE, in architecture, the lower part of the chimney, or that piece of timber which is laid acroſs the jaumbs, and ſuſtains the compartment of the chimney-piece. See the article CHIMNEY.

MANTLE, or MANTLING, in heraldry, that appearance of folding of cloth, flouriſhing or drapery, that is in any atchievement drawn about the coat of arms. It is ſuppoſed originally to be the repreſentation of a mantle, or military habit, worn by the ancient cavaliers over their armour to preſerve it from ruſt; or, as others hold, a ſhort covering only worn over the helmet, which in after-times was lengthened, and made to hang from the helmet below the whole ſhield.

The mantle is always ſaid in blazonry, to be doubled, that is, lined throughout with one of the furs, as ermin, pean, viary, &c.

MANUFACTURER, one who works up a natural product into an artificial commodity.

MANURE, any thing uſed for fattening and improving land.

There are various kinds of manure uſed in different parts of England for enriching the ſeveral ſoils, ſome of which have been already mentioned under the articles dung, chalk, lime, &c. which ſee: but there are others that might be uſed on many lands with ſucceſs.

All ſorts of marl and clay, ſpread over gravelly and ſandy land, are of vaſt advantage to it, by making it more ſolid and tenacious, as all kinds of ſand are to thoſe ſoils that conſiſt of a ſtiff loam or clay. Theſe kinds of manure are of laſting advantage. See the article SAND.

Tanner's bark, laid in a heap, and rotted, is alſo an excellent manure, eſpecially for ſtiff cold land, and one load of it will improve the ground more, and laſt longer, than two loads of the richeſt dung: when this manure is laid on graſs, it ſhould be done ſoon after Michaelmas, that the winter rains may waſh it into the earth: and where it is uſed for corn-land, it ſhould be ſpread on the ſurface before the laſt plowing, that it may be turned down for the fibres of the corn to reach it in the ſpring. Rotten vegetables of moſt ſorts alſo greatly enrich land, ſo that where other manure is ſcarce, theſe may be uſed with great ſucceſs; thus the weeds of ponds, lakes, and ditches, being dragged out juſt as they begin to flour, and laid on heaps to rot, will make excellent manure: but it is to be obſerved, that in rotting theſe vegetables, it will be proper to mix ſome earth, mud, or any other ſuch like ſubſtance with them, to prevent their taking fire in their fermentation; it will alſo be proper to cover the heaps with earth, mud, or dung, to detain the ſalts, otherwiſe many of the finer parts will evaporate in fermenting. The refuſe of kitchen-gardens, when laid on heaps and rotted, will alſo afford good manure for corn-land: and alſo fern mowed down while it is green and tender, and laid on heaps to rot, will make excellent manure; and by frequently mowing it, this troubleſome plant will be deſtroyed. The aſhes of all kinds of vegetables are alſo good manure for land, ſo that where the ground is over-run with buſhes, brambles, &c. if they are grubbed up in ſummer, ſpread abroad to dry, and then conſumed to aſhes, and ſpread over the land, they will greatly improve it. Rotten wood, and ſaw-duſt, when rotted, are a very good manure for ſtrong land, as are alſo bones, horns, ſhells, woollen rags, &c. and whatever ſerves to looſen its parts.

MANUSCRIPT, in matters of literature, denotes a written book, in contradiſtinction to a printed one. See BOOK.

MAP, a plane figure repreſenting the ſurface of the earth, or a part thereof, according to the laws of perſpective

ſpective; diſtinguiſhing the ſituation of cities, mountains, rivers, &c.

In maps, theſe three things are eſſentially requiſite. 1. That all places have the ſame ſituation and diſtance from the great circles therein, as on the globe, to ſhew their parallels, longitudes, zones, climates, and other celeſtial appearances. 2. That their magnitudes be proportionable to the real magnitudes on the globe. 3. That all places have the ſame ſituation, bearing and diſtance, as on the earth itſelf.

Maps are either univerſal, which exhibit the whole ſurface of the earth; or particular, which exhibit ſome particular part thereof: each kind is called geographical or land-maps, in contradiſtinction to hydrographical or ſea-maps, repreſenting the ſeas and ſea-coaſts, properly called charts.

As a map is a repreſentation of ſome part of the ſurface of the earth delineated upon a plane; the earth being round, no part of the ſpherical ſurface of it can be accurately exhibited upon a plane, and, therefore, ſome have propoſed the making of globular maps; for this purpoſe, a plate of braſs might be hammered, or at a leſs expence a piece of paſte-board might be formed into a ſegment of a ſphere, and covered on its convex ſide with a map projected in the ſame, as the papers of the common globes are: a map made in this method would ſhew every thing in the ſame manner, as it would be ſeen upon a globe of the ſame diameter with the ſphere upon the ſegment of which it was delineated: and, indeed, maps of this ſort would be in effect ſegments of ſuch a globe, but they are not in common uſe.

The ancients deſcribed all the parts of the known earth in one general map; in this view one of them compares the ſhape of the earth to the leather of a ſling, whoſe length exceeds its breadth: the length of the then known parts of the earth from eaſt to weſt was conſiderably greater than from north to ſouth; for which reaſon, the former of theſe was called the longitude, and the other the latitude.

The modern general maps are ſuch as give us a view of an entire hemiſphere, or half of the globe; and are projected upon the plane of ſome great circle, which terminates the projected hemiſphere, and divides it from the other half of the globe, as the equator, or the meridian, or horizon of ſome place: from this circle the projection is denominated, and ſaid to be equatorial, meridional, or horizontal.

Particular maps are ſuch as exhibit to us leſs than an hemiſphere; of this ſort are maps of the great parts into which the earth is divided, as Europe, Aſia, Africa, North-America, South-America; or maps of particular kingdoms, provinces, countries, or of leſſer diſtricts.

The projections of the circles in general maps are of two ſorts, convex and concave: to underſtand which we may imagine the globe upon which the circles are delineated to be of thin glaſs, and that half of it is viewed at a time; now we may be conceived to view this hemiſphere either on the convex or concave ſide, and we may conceive it to be placed at different diſtances from the eye: from which diverſity of our view, there will ariſe different projections, or pictures of it in a map. If the eye be ſuppoſed to be placed in ſome point of the ſurface of the ſphere to view the concave of the oppoſite hemiſphere, it is called the ſtereographic projection.

In this projection, the parts about the middle are a little contracted, ſo as to be too ſmall for the extreme parts, the reaſon whereof will appear from (plate LXXXIV. *fig.* 1.) hence, that if a concave ſemicircle with equal diviſions be viewed with the eye in the plane of it continued, at the diſtance of a ſemi-diameter from its center, the projection will be a ſtraight line unequally divided, the parts appearing leſs the nearer to the center; conſequently, if two ſemicircles cutting one another at right angles, drawn upon a concave hemiſphere, and marked with equal diviſions, be viewed in the manner now deſcribed, the projection of them will be ſtraight lines unequally divided, as A C and B D (*fig.* 2.) the parts appearing leſs the nearer to the center. The ſtereographic projection is either equatorial, meridional, or horizontal.

The equatorial projection ſuppoſes the eye to be ſituated in one of the poles of the earth, and from thence to view the oppoſite concave hemiſphere, with its circles, projected upon a plane of glaſs paſſing through the equator. Thus the eye is ſuppoſed to be in the north pole, in order to view the ſouthern hemiſphere; and in the ſouth pole to view the northern hemiſphere. Thus *fig.* 3. is a map of the northern hemiſphere upon that projection: here the meridians are all ſtraight lines, and the parallels are compleat circles.

The meridional projection ſuppoſes the eye to be in ſome point of the equator, and from thence to view the oppoſite concave hemiſphere, projected upon a glaſs plane paſſing through ſome meridian, which a meridian drawn through the eye cuts at right angles. Thus *fig.* 7. is a map of the earth in two hemiſpheres, projected upon the plane of a meridian paſſing through one of the Canary-iſlands called Ferro. This meridian is made choice of, becauſe, by making the projection thereon, one hemiſphere contains Europe, Aſia, and Africa; and the other North and South America. Here all the meridians are arches of circles, except that drawn through the eye, which is a ſtraight line; and all the parallels are arches of circles, and the equator is a ſtraight line.

M. de la Hire has invented another meridional projection, which comes the neareſt of all to the nature of the globe, becauſe the meridians are placed therein at equal diſtances, the parallels alſo are nearly equidiſtant, and conſequently the ſeveral parts of the earth have their proper proportion of magnitude, diſtance, and ſituation, nearly the ſame as on the globe itſelf. As this ſort of projections is very uſeful, and at the ſame time not very common, we have here added a theory thereof, and alſo a map of the two hemiſpheres of the earth delineated on theſe principles. See plate LXXXV. *fig.* 2.

A determination of the moſt perfect globular projections neceſſary for conſtructing geographical maps.

Let I B L be a ſemi-circle (*fig.* 1.) D the place of the eye in the diameter B C produced, through the center A draw L A I perpendicular to B C. Now if we ſuppoſe the ſemi-circle I B L to be divided into indefinitely ſmall equal parts as F *f*, *f* H, &c. and from D we draw the rays D F, D *f*, D H, &c. cutting the plane of projection L I in the points E, *e*, *b*, the parts E *e*, *e b*, are to be as nearly equal as poſſible, that is, their difference is to be leſs than if the rays had been drawn from any other point as *d*, in the diameter B C produced. This being premiſed, it will follow, that the ſum of the differences of all the parts into which A I is divided by the viſual rays drawn from D to the ſeveral points H, *f* F, &c. in the circumference of the ſemicircle, will be the leaſt poſſible, becauſe if the parts E *e*, *e b*, &c. could be perfectly equal, the ſum of their differences would entirely vaniſh.

Now in order to determine the point D, put the radius A B $= a$, A D $= u$, and imagine E *e* to be the greateſt of all the diviſions that can be made by two rays drawn from the point D to the correſponding points F, *f*, in the circumference. From F draw F G S parallel to I L, and join the points A, F. Call A G, x, and put s for the arch B F, whence G *g* or F M $= \dot{x}$, F *f* $= \dot{s}$; and therefore E A $= \frac{u\sqrt{a^2-x^2}}{x+u}$, which put $= z$; conſequently

E *e* $= \dot{z} = \frac{\overline{aa+ux} \times u\dot{x}}{\overline{u+x}^2 \times \sqrt{a^2-x^2}}$. But A F : F G :: *f* F : F M, which algebraically expreſſed gives $\dot{x} = \frac{\dot{s}}{a} \times \sqrt{a^2-x^2}$; ſubſtitute this value of $\dot{x}$ in the above value of $\dot{z}$, and we ſhall have $\dot{z} = \frac{\overline{aa+ux} \times u\dot{s}}{\overline{u+x}^2 \times a}$, and by taking the fluxion of this expreſſion with u and $\dot{s}$ invariable, we ſhall have $\overline{2u^2-2a^2-ru} \times \frac{u\dot{r}\dot{s}}{r^3 a} = 0$ (wherein $r = u+x$); therefore $\frac{u^2-2a^2}{u} = r = u+x$, and $u - \frac{2a^2}{u} = x$, the part E *e* being the greateſt of all others for the ſame value of u and $\dot{s}$.

If we now conſider the eye as placed at D, it will be eaſy to conceive that the laſt parts next to A and I reſpectively, cannot be determined from the fluxion of E *e*; it is alſo clear that the ſum of the parts E *e*, *e b*, is equal to

to the difference between the greateſt E e, and the neareſt to A, together with the difference between the ſame E e and that neareſt to I. It therefore only now remains to find an expreſſion for theſe extreme parts correſponding to the ſame value of u and $\dot{t}$: in order to which, let a be wrote for x in the value of E e, and then the laſt part next to the center A will become $\frac{\overline{a+u} \times a u \dot{t}}{a \times u \times a}$ or $\frac{u \dot{t}}{a+u}$, and by making $x = 0$, in the ſaid value, we ſhall have $\frac{a \dot{t}}{u}$ for the part next the point I. Now let $u - \frac{2aa}{u}$ be ſubſtituted for x in the above value of $\dot{z}$, viz. $\frac{\overline{aa+ux} \times u \dot{t}}{\overline{u+x} \times a}$; and after due reduction being made, we ſhall have $\frac{u^3 \dot{t}}{4au^2 - 4a^3}$ for the middle or mean part E e, correſponding to the extreme parts already found, namely, $\frac{u \dot{t}}{a+u}$ and $\frac{a \dot{t}}{u}$. If from the double of the mean particle E e we ſubtract the ſum of thoſe extremes, the remainder will give the ſum of their differences; that is, how much they differ from equality among themſelves, and which muſt, by the hypotheſis, be the leaſt poſſible: therefore $\frac{u^3 \dot{t}}{2au^2 - 2a^3} - \frac{u \dot{t}}{a+u} - \frac{a \dot{t}}{u}$ muſt be a minimum; this expreſſion being put into fluxions, with $\dot{t}$ invariable, and made equal to nothing, will produce $u^6 - 3a^2u^4 + 4a^3u^3 - 6a^4u^2 + 2a^6 = 0$, wherein if we take $a = 100$, u will become 160 very near.

Let IBLG now repreſent a ſphere; it is required to determine the point O in the diameter BC produced, from whence equal parts of the ſurface ſhall upon the plane of projection I L appear as nearly equal as poſſible among themſelves.

From O draw O S at pleaſure, and O s infinitely near it, cutting I A L in X and x. Put A B $= a$, A T $= x$, A X $= x$, A O $= u$, and c for the periphery of a circle, whoſe radius is a; then will $\mathrm{AX} = \dot{z} = \frac{u \times \sqrt{a^2 - x^2}}{u+x}$, and X x or $\dot{z} = \frac{\overline{aa+ux}}{\overline{x+u}^2} \times \frac{u \dot{x}}{\sqrt{a^2-x^2}}$. The periphery of the circle whoſe radius is G S is $\frac{c}{a} \times \sqrt{a^2-x^2}$, whence $\dot{z} + u : u :: \frac{c}{a} \times \sqrt{aa-xx} : \frac{uc \times \sqrt{aa-xx}}{\overline{x+u} \times a}$, which being multiplied by $\dot{z}$, gives $\frac{\overline{aa+ux}}{\overline{x+u}^3} \times \frac{u^2 c \dot{x}}{a}$, which, by ſubſtituting r for $u + x$, will become $\frac{\overline{a^2+ur-u^2} \times u^2 c \dot{x}}{r^3 \times a}$. Now as all the ſpherical zones are ſuppoſed equal to each other, it is evident that if the laſt expreſſion be put into fluxions with $\dot{r}$ conſtant, and made equal to nothing, there will ariſe an equation, from whence ſuch a value of AT may be found, as will determine the greateſt circular zone poſſible, correſponding to the equal ones upon the ſurface of the ſphere; hence, by taking the fluxion of $\frac{a^2+ur-u^2}{r^3 \times a} \times u^2$, and equating it as before directed, we get $3u^2 - 2ru = 3a^2$, or $r = \frac{3u}{2} - \frac{3a^2}{2u}$, and $\mathrm{AT} = \frac{u}{2} + \frac{3a^2}{2u}$. Having proceeded thus far, let the general expreſſion for the circular zone, viz. $\frac{\overline{a^2+ux} \times u^2 c \dot{x}}{\overline{x+u}^3 \times a}$ be again reſumed, and therein x made $= 0$; it will then become $\frac{ac\dot{x}}{u}$, an expreſſion for the zone next the point L; and again, if in the ſame general value $\frac{\overline{a^2+ux} \times u^2 c \dot{x}}{\overline{x+u}^3 \times a}$ we make $x = a$, there will ariſe $\frac{\overline{u^2 c \dot{x}}}{\overline{a+u}^2}$ for the zone next the point A; and laſtly, if for x we put its value, viz. $\frac{u}{2} - \frac{3a^2}{2u}$, when the zone is the greateſt it can be, we ſhall have $\frac{4u^5 c \dot{x}}{\overline{u^2-a^2}^2 \times 27a}$ for the value thereof; and conſequently the ſum of the differences found as before, by ſubtracting the ſum of the extremes from double the mean, will be expreſſed by $\frac{8u^5 c \dot{x}}{\overline{u^2-a^2}^2 \times 27a} - \frac{u^2 c \dot{x}}{\overline{a+u}^2} - \frac{ca\dot{x}}{u}$, which muſt be the leaſt poſſible, in fluxions, with $\dot{x}$ conſtant and u variable, gives $\frac{8\dot{u}}{27a} \times \frac{5a^4u^4 - 6a^2u^6 + u^8}{\overline{u^2-a^2}^4} = \frac{\overline{2au+a}}{\overline{a+u}^3} \times \frac{\dot{u}}{u^2}$, which may be farther reduced to $8u^8 - 121a^2u^6 + 162a^3u^5 - 81a^4u^4 + 54a^5u^3 - 81a^6u^2 + 27a^8 = 0$, from whence (making $a = 100$) u will be found equal to 210.5 very near: and conſequently the point O is determined.

In the horizontal projection the eye is ſuppoſed to be in that point of the ſurface of the globe, which is diametrically oppoſite to the place upon the horizon of which the projection is made, and from thence to view the oppoſite concave hemiſphere, with its circles projected upon a glaſs plane paſſing through that horizon. Thus, if we project any map of this ſort upon the horizon of London, the eye is ſuppoſed to be in the place of the antipodes to London, and from thence to view the concave hemiſphere. There is great variety in this ſort of projection; for if the place, the horizon it is upon, be under the pole, the horizontal projection is the ſame with the equatorial already deſcribed. If the place be under the equator, it is the ſame with the meridional: if the place be in an oblique ſphere, the projection will be different, according to the different latitude of the place; for it will approach nearer to an equatorial or meridional projection, according as the place is ſituated nearer to one of the poles, or to the equator. Plate LXXXIV. *fig.* 4. is a map projected upon the horizon of London, whoſe latitude is 51° 32′. The chief advantage of this kind of maps is this, that the place upon the horizon on which the map is projected is always in the center of it, and we may ſee the bearings of places from it.

A particular map is a part of a general one, and may be made upon the ſame principles, as by projecting a large hemiſphere, and taking ſo much of it as the map is deſigned to contain. When we are to delineate a map of a ſmaller part of the earth, if it be near the equator, the meridians and parallels may be repreſented by equidiſtant right-lines. If at ſome diſtance from the equator, the parallels may be equidiſtant ſtraight-lines, and the meridians ſtraight-lines, a little converging towards the neareſt pole: or the meridians may be ſtraight-lines, converging towards the neareſt pole, and the parallels circular.

When we are to make a map of a very ſmall diſtrict, as of a county or hundred, whatever part of the earth it be in, the meridians and parallels may be equidiſtant ſtraight-lines, drawn through every minute, &c. of longitude, according as the largeneſs of the map will allow. See PLOTTING and SURVEYING.

If the eye be ſuppoſed to view the hemiſphere at an infinite diſtance, the projection of its circles, whether it be viewed on the convex or concave ſide, is called orthographic. In this projection, the parts about the middle are very well exhibited, but the extreme parts are very much contracted. See *Orthographic* PROJECTION *of the Sphere*.

Fig. 5. is a general map of the northern hemiſphere projected orthographically upon the plane of the equator. Here the meridians are all ſtraight-lines, and the parallels are compleat circles. *Fig.* 6. is a general map of an hemiſphere projected orthographically on the plane of the meridian. Here all the meridians are projected into ſemi-ellipſes, except that which is perpendicular

cular to the plane of projection, and which becomes a ſtraight-line thereon. This projection has one advantage not to be found in any other general map; namely, that the decreaſe of the parallels from the equator to the poles, appears therein in true proportion.

The orthographic horizontal projection has great variety, according to the different latitude of places, and is pretty difficult to execute. Plate LXXXV. *fig.* 3. is a map of this kind, whoſe center is Ur of the Chaldees, and therefore projected on the horizon of that place.

The great contraction of the extreme parts in the orthographic projection makes it ſo deficient in the ſecond quality required in maps, that it is ſeldom uſed, except when the diſk of the earth, in a ſolar eclipſe, is to be exhibited.

The uſe of maps is obvious from their conſtruction. The degrees of the meridians and parallels ſhew the longitude and latitude of places; their bearings from each other appear from inſpection; and their diſtances may be meaſured by the diviſions on the meridian, equator, &c.

MAPLE, *Acer*, in botany, a genus of plants, the flower of which is compoſed of five oval petals; the fruit conſiſts of a number of capſules, which grow together at the baſe; and are compreſſed, roundiſh, and each terminated by a very large membranous ala; the ſeeds are ſingle and roundiſh.

Great MAPLE, *acer majus*, improperly called ſycamore, a large tree with pentangular ſerrated leaves; producing ſmall greeniſh flowers, and a fruit compoſed of two capſules, including, each, a whitiſh ſeed at the end where they are joined, and ſpreading at the oppoſite end into a membranous wing. It is a native of the mountains of Switzerland and Auſtria, and now common in England.

Theſe trees are propagated by ſowing the ſeeds, ſoon after they are ripe, in an open bed of common earth, covering them about half an inch thick, with ſandy light earth: the ſpring following they will appear above ground, and, if kept clear from weeds, will grow above a foot high the firſt ſummer: the Michaelmas following, if they are thick in the ſeed-bed, you may take out a part of them, and tranſplant into a nurſery, in rows at three feet diſtance, and two feet aſunder in the rows; in which place they may remain three or four years, when they will be large enough to plant out for good. The timber of the common maple is far ſuperior to the beech for all uſes of the turner, particularly diſhes, cups, trenchers, and bowls; and when it abounds with knots, as it very often doth, it is highly eſteemed by the joiners for inlayings, &c. and alſo, for the lightneſs of the wood, is often employed by thoſe that make muſical inſtruments; and, for the whiteneſs of the wood, is in great requeſt for tables.

All the parts of the maple contain a ſweet ſaccharine juice; which exuding on the ſurface of the leaves, renders them ſubject to be preyed on by inſects. The roots, trunk, or branches, wounded early in the ſpring, bleed a large quantity of clear liquor; which, in its dilute ſtate, taſtes ſomewhat ſweetiſh; and, on being inſpiſſated, yields a brown coloured concrete ſugar, with a ſyrupy matter reſembling melaſſes.

The juice, unboiled, has been drank as an antiſcorbutic. The ſugar and melaſſes, which are leſs ſweet than thoſe extracted from the ſugar-cane, and whoſe ſweetneſs is likewiſe ſomewhat different in kind, are ſuppoſed to be more medicinal in diſorders of the breaſt. Conſiderable quantities of this ſugar, made from a ſpecies of maple in Canada, are imported for that uſe into ſome parts of Europe, particularly France.

MARBLE, *Marmor*, in natural hiſtory, a genus of foſſils, being bright and beautiful ſtones, compoſed of ſmall ſeparate concretions, moderately hard, not giving fire with ſteel, fermenting with and ſoluble in acid menſtrua, and calcining in a ſlight fire.

The colours of marbles being a very obvious and ſtriking character, they are arranged according to them, in the following diviſions. 1. Of the white plain marbles there are two ſorts; the Parian marble of the ancients, and ſtatuary marble of the moderns, an extremely bright and elegant marble; and the Carrara marble; a very fine marble, more compact and cloſe than the former, but leſs bright. 2. Of the plain yellowiſh marbles there is only one ſort, which is a hard, pale yellow, and gloſſy marble, found in many parts of Italy. 3. Of the bluiſh and black marbles there are a great many ſpecies, as the Chian marble, Baſaltes, &c. 4. Of the plain green marbles there is only one kind, the Lacedemonian marble of the ancients. 5. The pale-coloured or whitiſh brown, commonly called Darby-marble. 6. The green marbles with ſhells. 7. The black Coralloide marble, with and without ſhells. 8. Of the white variegated marble there are a great many ſpecies, variegated with purple, brown, red, blue, &c. 9. Of the brown variegated marbles there are likewiſe ſeveral ſorts, ſome with red veins, others with white, black, or brown veins. 10. Of the yellow veined and variegated marbles ſome are veined with purple, and others with blue. 11. Of the black variegated marbles, ſome are veined with white, and others with blue, yellow, red, &c. 12. The green variegated marbles are likewiſe diſtinguiſhed by the colour of their veins. 13. The grey ſpotted marbles are variegated, ſome with black and others with green ſpots. 14. The red variegated marble is the Brocatello of the Italians, with white and gold veins.

Poliſhing of MARBLE is performed by firſt rubbing them well with a free-ſtone, or ſand, till the ſtrokes of the axe are worn off, then with pumice-ſtone, and afterwards with emery.

Colouring of MARBLE.—The colouring of marble is a nice art, and in order to ſucceed in it, the pieces of marble, on which the experiments are tried, muſt be well poliſhed, and clear from the leaſt ſpot or vein. The harder the marble is, the better it will bear the heat neceſſary in the operation; therefore, alabaſter and the common ſoft white marble are very improper to perform theſe operations upon.

Heat is always neceſſary for the opening the pores of the marble, ſo as to render it fit to receive the colours; but the marble muſt never be made red-hot, for then, the texture of the marble itſelf is injured, and the colours are burnt, and loſe their beauty. Too ſmall a degree of heat is as bad as too great; for, in this caſe, though the marble receive the colour, it will not be fixed in it, nor ſtrike deep enough. Some colours will ſtrike even cold, but they are never ſo well ſunk in as when a juſt degree of heat is uſed. The proper degree is that which, without making the marble red, will make the liquor boil upon its ſurface. The menſtruums uſed to ſtrike in the colours, muſt be varied according to the nature of the colour to be uſed. A lixivium made with horſe's or dog's urine, with four parts quick-lime, and one part pot-aſhes, is excellent for ſome colours; common ley of wood-aſhes does very well for others: for ſome, ſpirit of wine is beſt; and, finally, for others, oily liquors, or common white-wine.

The colours which have been found to ſucceed beſt with the peculiar menſtruums, are theſe: ſtone-blue diſſolved in ſix times the quantity of ſpirit of wine, or of the urinous lixivium; and that colour which the painters call litmouſe, diſſolved in common ley of wood-aſhes. An extract of ſaffron, and that colour made of buckthorn berries, and called by the painters ſap green, both ſucceed well diſſolved in urine and quick-lime, and tolerably well in ſpirit of wine. Vermilion, and a fine powder of cochineal, ſucceed alſo very well in the ſame liquors. Dragon's blood ſucceeds very well in ſpirit of wine, as does alſo a tincture of logwood, in the ſame ſpirit. Alkanet root gives a fine colour, but the only menſtruum to be uſed for this is oil of turpentine; for neither ſpirit of wine, nor any lixivium, will do with it. There is another kind of ſanguis draconis called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. *Philoſ. Tranſact.* N°. 268.

Beſides theſe mixtures of colours and menſtruums, there are ſome colours which are to be laid on dry and unmixed. Theſe are dragon's blood, of the pureſt kind, for a red; gamboge for a yellow; green-wax for a green; common brimſtone, pitch, and turpentine, for a brown colour. The marble, for theſe experiments, muſt be made conſiderably hot, and then the colours are to be rubbed on dry in the lump. Some of theſe colours, when once

once given, remain immutable; others are eaſily changed or deſtroyed. Thus the red colour given by dragon's blood, or by a decoction of logwood, will be wholly taken away by oil or tartar, and the poliſh of the marble not hurt by it.

A fine gold colour is given in the following manner: take crude ſal armoniac, vitriol, and verdigreaſe, of each equal quantities; white vitriol ſucceeds beſt, and all muſt be thoroughly mixed in fine powder.

The ſtaining of marble to all the degrees of red or yellow, by ſolutions of dragon's blood or gamboge, may be done by reducing theſe gums to powder, and grinding them, with the ſpirit of wine, in a glaſs mortar; but, for ſmaller attempts, no method is ſo good as the mixing a little of either of theſe powders with ſpirit of wine, in a ſilver ſpoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and, with a pencil dipped in this, the fineſt traces may be made on the marble, while cold, which, on the heating it afterwards, either on ſand, or in a baker's oven, will all ſink very deep, and will remain perfectly diſtinct in the ſtone. It is very eaſy to make the ground colour red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whiteneſs is to remain, with ſome white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to marble by means of this gum alone; a ſlight tincture of it, without the aſſiſtance of heat to the marble, gives only a pale fleſh colour, but the ſtronger tinctures give it yet deeper; to this the aſſiſtance of heat adds yet greatly; and, finally, the addition of a little pitch to the tincture gives it a tendency to blackneſs, or any degree of deep red that is deſired.

A blue colour may be given alſo to marble by diſſolving turnſol in a lixivium of lime and urine, or in the volatile ſpirit of urine; but this has always a tendency to purple, whether made by the one or the other of theſe ways. A better blue, and uſed in a eaſier manner, is furniſhed by the Canary turnſol, a ſubſtance well known among the dyers: this needs only to be diſſolved in water, and drawn on the place with a pencil; this penetrates very deep into the marble, and the colour may be increaſed by drawing the pencil, wetted afreſh, ſeveral times over the ſame lines. This colour is ſubject to ſpread and diffuſe itſelf irregularly; but it may be kept in regular bounds, by circumſcribing its lines with beds of wax, or any other ſuch ſubſtance. It is to be obſerved, that this colour ſhould be always laid on cold, and no heat given even afterwards to the marble; and one great advantage of this colour is, that it is therefore eaſily added to marble already ſtained with any other colours, and it is a very beautiful tinge, and laſts a long time. *Mem. Acad. Par.* 1732.

Arundel MARBLES, ancient marbles with a chronicle of the city of Athens inſcribed on them, many years before our Saviour's birth; preſented to the univerſity of Oxford by Thomas earl of Arundel, whence the name.

MARBLING, the method of preparing and colouring the marbled paper.

There are ſeveral kinds of marbled paper; but the principal difference of them lies in the forms in which the colours are laid on the ground: ſome being diſpoſed in whirles or circumvolutions; ſome in jagged lengths; and others only in ſpots of a roundiſh or oval figure. The general manner of managing each kind is, nevertheleſs, the ſame; being the dipping the paper in a ſolution of gum-tragacanth, or, as it is commonly called, gum-dragon; over which the colours, previouſly prepared with ox-gall and ſpirit of wine, are firſt ſpread.

The peculiar apparatus neceſſary for this purpoſe, is a trough for containing the gum tragacanth, and the colours; a comb for diſpoſing them in the figure uſually choſen; and a burniſhing ſtone for poliſhing the paper. The trough may be of any kind of wood; and muſt be ſomewhat larger than the ſheets of paper, for marbling which it is to be employed; but the ſides of it need only riſe about two inches above the bottom; for by making it thus ſhallow, a leſs quantity of the ſolution of the gum will ſerve to fill it. The comb may be alſo of wood, and five inches in length; but ſhould have braſs teeth, which may be about two inches long, and placed at about a quarter of an inch diſtance from each other. The burniſhing ſtone may be of jaſper, or agate; but as thoſe ſtones are very dear, when of ſufficient largeneſs, marble or glaſs may be uſed, provided their ſurface be poliſhed to a great degree of ſmoothneſs.

Theſe implements being prepared, the ſolution of gum-tragacanth muſt be made, by putting a ſufficient proportion of the gum, which ſhould be white, and clear from all foulneſſes, into clean water; and letting it remain there a day or two, frequently breaking the lumps and ſtirring it, till the whole ſhall appear diſſolved, and equally mixed with the water. The conſiſtence of the ſolution ſhould be nearly that of ſtrong gum-water, uſed in miniature painting; and if it appear thicker, water muſt be added, or if thinner, more of the gum. When the ſolution is thus brought to a due ſtate, it muſt be paſſed through a linen cloth, and being then put into the trough, it will be ready to receive the colours.

The colours employed for red are carmine, lake, roſe-pink, and vermilion; but the two laſt are too hard and glaring, unleſs they be mixed with roſe-pink, or lake, to bring them to a ſofter caſt: and with reſpect to the carmine and lake, they are too dear for common purpoſes: —for yellow, Dutch pink and yellow oker may be employed: — for blue, Pruſſian blue and verditer may be uſed: — for green, verdigriſe, a mixture of Dutch pink and Pruſſian blue, or verditer, in different proportions: — for orange, the orange-lake, or a mixture of vermilion, or red lead, with Dutch pink: — for purple, roſe-pink and Pruſſian blue.

Theſe ſeveral colours ſhould be ground with ſpirit of wine till they be of a proper fineneſs; and then, at the time of uſing them, a little fiſh-gall, or in default of it, the gall of a beaſt ſhould be added, by grinding them over again with it. The proper proportion of the gall muſt be found by trying them; for there muſt be juſt ſo much as will ſuffer the ſpots of colour, when ſprinkled on the ſolution of the gum-tragacanth, to join together, without intermixing or running into each other.

When every thing is thus prepared, the ſolution of the gum-tragacanth muſt be poured into the trough; and the colours, being in a ſeparate pot, with a pencil appropriated to each, muſt be ſprinkled on the ſurface of the ſolution, by ſhaking the pencil, charged with its proper colour, over it; and this muſt be done with the ſeveral kinds of colour deſired, till the ſurface be wholly covered.

When the marbling is propoſed to be in ſpots of a ſimple form, nothing more is neceſſary; but where the whirles or ſnail-ſhell figures are wanted, they muſt be made by means of a quill; which muſt be put among the ſpots to turn them about, till the effect be produced. The jagged lengths muſt be made by means of the comb above deſcribed, which muſt be paſſed through the colours from one end of the trough to the other; and will give them that appearance; but if they be deſired to be pointed both ways, the comb muſt be again paſſed through the trough in a contrary direction; or if ſome of the whirles or ſnail-ſhell figures be required to be added, they may be yet made by the means before directed.

The paper ſhould be previouſly prepared for receiving the colours, by dipping it over night in water; and laying the ſheets on each other with a weight over them. The whole being thus ready, the paper muſt be held by two corners, and laid in the moſt gentle and even manner on the ſolution covered with the colours; and there ſoftly preſſed with the hand, that it may bear every where on the ſolution. After which it muſt be raiſed and taken off with the ſame care, and then hung to dry acroſs a proper cord, ſubtended near at hand for that purpoſe: and in that ſtate it muſt continue, till it be perfectly dry. It then remains only to give the paper a proper poliſh; in order to which it is firſt rubbed with a little ſope; and then muſt be thoroughly ſmoothed by the glaſs poliſhers, ſuch as are uſed for linen, and called the calender glaſſes. After which it ſhould be again rubbed by a burniſher of jaſper or agate; or, in default of them, of glaſs ground to the higheſt poliſh: for on the perfect poliſh of the paper depends in a great meaſure its beauty and value.

Gold or ſilver powders may be uſed, where deſired, a long with the colours; and require only the ſame treatment as them, except that they muſt be firſt tempered with gum-water.

Marbling of books or paper is performed thus: diſſolve four ounces of gum-arabic into two quarts of fair water; then provide ſeveral colours mixed with water in pots or ſhells, and with pencils peculiar to each colour, ſprinkle them by way of intermixture upon the gum-water, which muſt be put into a trough, or ſome broad-veſſel; then with a ſtick curl them, or draw them out in ſtreaks, to as much variety as may be done. Having done this, hold your book or books cloſe together, and only dip the edges in, on the top of the water and colours, very lightly; which done, take them off, and the plain impreſſion of the colours in mixture will be upon the leaves; doing as well the ends as the front of the book in the like manner.

Marbling a book on the covers is performed by forming clouds with aqua fortis, or ſpirit of vitriol mixed with ink, and afterwards glazing the covers. See the article BOOK-BINDING.

MARCASITES, *Marchaſitæ*, in natural hiſtory, are defined to be compound inflammable metallic bodies, of a hard and ſolid ſubſtance, of an obſcurely and irregularly foliaceous ſtructure, of a bright glittering appearance, naturally conſtituting whole ſtrata, though ſometimes found in detached maſſes; very freely giving fire with ſteel; not fermenting with acid menſtruums; and when put into the fire, yielding a blue ſulphureous flame, and afterwards calcining into a purple powder.

There are only three known ſpecies of this genus: 1. The ſilver-coloured marcaſite, found in vaſt abundance in lead and tin-mines. 2. The gold-coloured marcaſite. 3. The heavy pale-white marcaſite.

Marcaſites were at firſt ſuppoſed to be almoſt all pure gold or ſilver, according to their colour; but experience has ſhewn, that if they contain any metal at all, no method has hitherto been found of working them to advantage. In Germany, indeed, they extract ſulphur and vitriol from the ſilver marcaſite, which two ſubſtances are always contained in it; and beſides theſe, it has uſually a quantity of arſenic. It has been recommended as a ſtyptic, after being calcined; but as the arſenic may not be all carried off by that operation, its uſe as a medicine ſeems extremely dangerous.

MARCGRAVE, or MARGRAVE, a degree of honour in Germany anſwering to our marquis. See the article MARQUIS.

MARCH, in chronology, the third month of the year, conſiſting of thirty-one days. See the articles MONTH and YEAR.

MARCIONITES, Chriſtian heretics in the ſecond century, thus denominated from their leader Marcion, who maintained, that there were two principles or Gods, a good and a bad one. Origen affirms, that he held there was a God of the Jews, a God of the Chriſtians, and a God of the Gentiles. It is ſaid that he denied the reſurrection of the body, condemned marriage, and taught that our Saviour, when he deſcended into hell, diſcharged Cain, the Sodomites, and other impious wretches out of that place of torment. He rejected all the Old Teſtament, and received only part of St. Luke's Goſpel, and ten of St. Paul's epiſtles, in the New.

MARCOSIANS, a ſect of Chriſtian heretics in the ſecond century, ſo called from their leader Marcus, who repreſented the ſupreme God as conſiſting not of a trinity, but a quaternity, viz. the ineffable, ſilence, the father, and truth. He held two principles, denied the reality of Chriſt's ſufferings, and the reſurrection of the body, and had the ſame fancies concerning the æons as Valentinus. See the articles ÆONS and VALENTINIANS.

The Marcoſians, it is ſaid, made pretences to greater perfection than either St. Paul or St. Peter; and being perſuaded that nothing could hinder their ſalvation, freely indulged themſelves in the practice of vice.

MARDIKERS, or TOPASSES, a mixed breed of Dutch, Portugueſe, Indians, and other nations, incorporated with the Dutch at Batavia, in the Eaſt-Indies.

MARE, the female of the horſe-kind. See the article HORSE.

Such mares as are deſigned for breeding, ought to be as free from defects as poſſible, and ſhould, no more than the ſtallions, have either moon-eyes, watery-eyes, or blood-ſhot eyes; they ſhould have no ſplint, ſpavin, or curb, nor any natural imperfection; for the colts will take after them: but choice ſhould be made of the beſt and ableſt, the moſt high-ſpirited, beſt coloured, and fineſt ſhaped; and the natural defects that may be in the ſtallion, ſhould be amended in the mare, as well as that which is amiſs in the mare ſhould be amended in the ſtallion.

As for her age, ſhe may be covered when three years old; but the moſt convenient time is after four, when ſhe will nouriſh her colt beſt; and though ſhe may breed till ſhe is thirteen, yet ſhe is not fit for it when ſhe is paſt ten, for the colt of an old mare is commonly heavy. Before a mare is covered, ſhe ſhould be in the houſe about ſix weeks, during which time ſhe ſhould be well fed with good hay and oats well ſifted; and in order to render her conception the more certain, near a quart of blood may be taken from each ſide of her neck, about five or ſix days before covering. Another method to bring a mare in ſeaſon, and make her retain, is to give her, for the ſpace of eight days before you bring her to the horſe, about two quarts of hemp-ſeed in the morning, and as much at night; and if ſhe refuſes to eat it, to mingle it with a little bran or oats, or elſe to let her faſt for a while: and if the ſtallion alſo eat of it, it will greatly contribute to generation.

Mares go with foal eleven months and as many days as they are years old; and therefore the propereſt time for covering them is in the beginning of June, that ſhe may foal the May following, when there will be plenty of graſs, which will afford the mares a great abundance of milk for nouriſhing their foals: but a mare ſhould never be covered while ſhe is bringing up her foal, becauſe the foal to which ſhe is giving ſuck, as well as that in her belly, will be prejudiced by it, and ſhe herſelf ſooner ſpent. After covering, let her, for three weeks or a month, have the ſame diet as before, and be kept clean in the ſtable till the middle of May, with her feet well pared and thin ſhod: take her in again about the latter end of September, if not before, and keep her to the end of her foaling. If ſhe cannot readily bring forth, hold her noſtrils ſo as to ſtop her taking wind; and if that will not do, diſſolve madder, to the quantity of a walnut, in a pint of ale, and give it her warm. In caſe ſhe cannot void her ſecundine, or after-burden, boil two or three handfuls of fennel in running-water, then put half a pint of that liquor into as much ſack, or, for want thereof, into a pint of ale, with a fourth part of ſallad-oil, mixed together, and pour it luke-warm into her noſtrils, holding them cloſe for ſome time: otherwiſe give her green wheat, or rye, the laſt of which is beſt.

If the mare has but little milk, boil as much as you can get from her, with the leaves of lavender and ſpike, and bathe the udder with it warm, till the knobs and knots are diſſolved. She ſhould now drink only white water, which is bran put into water; give her alſo ſweet maſhes: and a month after foaling let her have a maſh with ſome brimſtone or ſavin in it.

MARJORAM, *Majorana*, in botany, &c. See MAJORANA.

MARITIME, ſomething relating to, or bounded by the ſea: thus, a maritime province, or country, is one bounded by the ſea; and a maritime kingdom, or ſtate, is one that makes a conſiderable figure, or is very powerful at ſea.

MARK, in commerce, a certain note which a merchant puts upon his goods, or upon the caſk, hogſhead, &c. that contains them, in order to diſtinguiſh them from others.

St. MARK *the Evangeliſt's Day*, a feſtival of the Chriſtian church, obſerved April 25.

St. MARK's *Goſpel*, a canonical book of the New Teſtament, being one of the four Goſpels.

St. Mark wrote his Goſpel at Rome, where he accompanied St. Peter, in the year of Chriſt 44. Tertullian and others pretend, that St. Mark was no more than an amanuenſis to St. Peter, who dictated this Goſpel to him; others affirm, that he wrote it after St. Peter's death. Nor

are the learned leſs divided as to the language this Goſpel was wrote in; ſome affirming it was compoſed in Greek, others in Latin. Several of the ancient heretics received only the Goſpel of St. Mark; others among the Catholics rejected the twelve laſt verſes of this Goſpel. The Goſpel of St. Mark is properly an abridgment of that of St. Matthew.

Canons of St. MARK, a congregation of regular canons founded at Mantua, by Albert Spinola, a prieſt, towards the end of the twelfth century. Spinola made a rule for them, which was approved, corrected, and confirmed by ſeveral ſucceeding popes. About the year 1450, they were reformed, and followed only the rule of St. Auguſtine. This congregation having flouriſhed for the ſpace of four hundred years, declined by little and little, and is now become extinct.

Knights of St. MARK, an order of knight hood in the republic of Venice, under the protection of St. Mark the evangeliſt. The arms of the order are, gules, a lion winged or, with this device, PAX TIBI MARCE EVANGELISTA. This order is never conferred but on thoſe who have done ſignal ſervice to the commonwealth.

MARK, or MARC, alſo denotes a weight uſed in ſeveral ſtates of Europe, and for ſeveral commodities, eſpecially gold and ſilver. In France, the mark is divided into eight ounces, or ſixty-four drams, or one hundred and ninety-two deniers, or penny-weights, or one hundred and ſixty eſterlines, or three hundred mailles, or ſix hundred and forty ſelins, or four thouſand ſix hundred and eight grains. In Holland, the mark-weight is alſo called troy-weight, and is equal to that of France. When gold and ſilver are ſold by the mark, it is divided into twenty-four carats. See the article CARACT.

MARK is alſo uſed among us for a money of account, and in ſome other countries for a coin.

The Engliſh mark is two thirds of a pound ſterling, or thirteen ſhillings and fourpence; and the Scotch mark is of equal value in Scotch money of account. The mark-lubs, or Lubeck mark, uſed at Hamburg, is alſo a money of account, equal to one third of the rix-dollar, or to the French livre; each mark is divided into ſixteen ſols-lubs. Mark-lubs is alſo a Daniſh coin equal to ſixteen ſols-lubs. Mark is alſo a copper and ſilver coin in Sweden. See the article EXCHANGE.

MARKET, a public place in a city or town in which live cattle, proviſions, or other goods, are ſet to ſale; and alſo a privilege, either by grant or preſcription, by which a town is enabled to keep a market.

MARLE, *Marga*, a kind of dry, ſoft, foſſile earth, uſed for manuring land.

The word is derived from the old Celtic *marga*, mentioned by Pliny, and afterwards called margilla.

The principal ſorts of marle are the white and red. Too much of it thrown on the ground is found to burn it. Marle is burnt like other ſtone for making of lime.

It is a very material circumſtance in the marling of land, to find out how much the land requires of this manure; and, till experience has thoroughly ſhewn this, it is better to err in laying on too little, than too much; becauſe the latter is a fault not to be remedied. It is to be obſerved alſo, that marle never makes ſo great an improvement on land the firſt year, as it does afterwards.

In Staffordſhire they lay two hundred loads of marle upon an acre of land of the common kind; but where the ſoil is black, looſe, and ſandy, or full of worms, they will lay on three or four hundred loads to an acre; it being a rule with them, that this ſort of ſoil cannot be marled too much. If the mould be thin, the leſs marle does; if deep, it muſt have the more.

It is beſt ſowing of marled lands under furrow; becauſe if theſe lands are well huſbanded, they will be very mellow and hollow, which will occaſion the earth's ſinking from the roots of the corn, if it ſtand too high. If marle fattens land, or makes it ſtiff or binding, it muſt be well dunged, and laid down for graſs. In Staffordſhire, after their land is marled, their way is to take the crops following. After the firſt crop of wheat is off, they plow in the wheat ſtubble in December, and if the weather proves froſty, to mellow it, they do not plow it again till April. They then ſow it with barley, allowing three buſhels of ſeed to an acre. The common produce of this is thirty buſhels. After this they ſow peaſe, for which they plow once in the February following, allowing only three buſhels of ſeed to an acre, as in the barley. Next after this, if they intend ſix crops, they ſow wheat again upon the peaſe-crop; the fifth crop is barley again; and the ſixth year's is red oats. Some ſow two or three crops more, when the ground has been well marled, but that is much better let alone.

In digging for the marle they uſe in manuring the lands, in Ireland, they meet with foſſil horns, and other curious foſſils. The marle always lies in the bottom of low bogs. It is never met with in any other places, and is found by boring with augres made for that purpoſe. It uſually lies at five, ſeven, or nine feet depth. The obtaining it in many places is attended with very conſiderable expences, in draining off the water. The manner of digging it is this: they employ ſix able labourers and a ſupernumerary; and theſe cut up a hole of twelve feet ſquare; which is ſuppoſed a pit that this number of men can manage in a day. Two men dig, two throw it up, and two throw it by, and the ſupernumerary ſupplies defects on all occaſions. For the firſt three feet they dig through a fuzzy earth, fit for making a turf for fuel. Under this lies a ſtratum of gravel, of about half a foot. Under this often, for three feet more, there is a more kindly moſs, which would make better fuel. This lower ſtratum of turf is always full of foſſil wood, which is uſually ſo ſoft, that the ſpade cuts as eaſily through it, as through the earth it lies in. Under this, for about three inches, is found a ſeries of leaves, principally of the oak; theſe appear very fair to the eye, but fall to pieces on touching; and this ſtratum is ſometimes interrupted with vaſt heaps of ſeed, which ſeem to be of the broom or furze. In ſome places there appear berries of different kinds; and in others, ſeveral ſpecies of ſea plants, all lying in the ſame confuſed manner as the oak leaves. Under this vegetable ſtratum, there lies one of blue clay, half a foot thick, and uſually full of ſea ſhells. This blue clay is not ſo tough as the common ſort, but is thrown carefully up, and uſed as marle in ſome places. Under this always appears the right marle; the ſtratum of this is uſually from two to four feet thick, and ſometimes much more. *Philoſophical Tranſactions.* N°. 394.

Dice MARLE, in huſbandry, a name given by the people of Staffordſhire to a reddiſh marle, that breaks into ſmall ſquare pieces like dice, or elſe into thin flakes, in the manner of lead ore, and looks ſmooth on the ſurface.

MARLINE, amongſt ſeamen, a ſmall cord or line, uſed to faſten the ſtrops of blocks, &c. See BLOCK.

MARLINE-SPIKE, a kind of iron pin, with a large head, and tapering at the other end to a point. It is employed to penetrate the twiſts or ſtrands of rope in the time of ſplicing, &c. which is joining the end of one rope to another. See the article SPLICE.

The marline-ſpike is alſo uſeful for many other purpoſes of a ſimilar nature.

MARMALADE, a confection of plums, apricots, quinces, &c. boiled with ſugar to a proper conſiſtence.

MARMOR, *marble.* See MARBLE.

MARMOTTE, in zoology, the largeſt animal of the mus or rat kind, with a long naked tail and tawney body; it is near as big as a hare, and breeds only on the tops of mountains in Switzerland. Its feet are ſomewhat like thoſe of a bear.

MARONITES, in church-hiſtory, a ſect of chriſtians near mount Libanus in Syria, who are in communion with the church of Rome, and have their patriarch, archbiſhops, biſhops, &c.

MARQUE, or *Letters of* MARQUE, in military affairs, are letters of repriſal, granting the ſubjects of one prince or ſtate liberty to make repriſals on thoſe of another.

Letters of marque, among us, are extraordinary commiſſions granted by authority, for reparation to merchants, taken and deſpoiled by ſtrangers at ſea; and repriſals is only the retaking, or taking of one thing for another.

MARQUETRY, or INLAID-WORK, is a curious work compoſed of ſeveral fine pieces of wood, of various colours,

colours, faſtened in thin ſlices on a ground, and ſometimes enriched with other matters, as ſilver, braſs, tortoiſe-ſhell, and ivory; with theſe aſſiſtances the art is now capable of imitating any thing; whence it is by ſome called the art of painting in wood.

The ground on which the pieces are to be arranged and glued, is uſually of well-dried oak or deal, and is compoſed of ſeveral pieces glued together, to prevent its warping. The wood to be uſed in marquetry is reduced into leaves of the thickneſs of a line, or the twelfth part of an inch, and is either of its natural colour, or ſtained, or made black to form the ſhades by other methods: this ſome perform by putting it in ſand heated very hot over the fire; others, by ſteeping it in lime water and ſublimate; and others, in oil of ſulphur. The wood being of the proper colours, the contours of the pieces are formed according to the parts of the deſign they are to repreſent: this is the moſt difficult part of marquetry, and that which requires the moſt patience and attention.

The two chief inſtruments uſed in this work, are a ſaw and a wooden vice, which has one of its chaps fixed, and the other moveable, which is open and ſhut by the foot, by means of a cord faſtened to a treddle. See plate LXXXIII. *fig.* 6.

The leaves to be formed, of which there are frequently three, four, or more joined together, are, after they have been glued on the outermoſt part of the deſign, whoſe profile they are to follow, put within the chaps of the vice; then the workman preſſing the treddle, and thus holding faſt the piece, with his ſaw runs over all the out-lines of his deſign. By thus joining or forming three or four pieces together, not only time is ſaved, but alſo the matter is the better enabled to ſuſtain the effort of the ſaw, which, how fine ſoever it may be, and how ſlightly ſoever it may be conducted by the workman, except this precaution were taken, would be apt to raiſe ſplinters, and ruin the beauty of the work. All the pieces having been thus formed by the ſaw, and marked, in order to their being known again, each is vaneered, or faſtened in its place, on the common ground, with the beſt Engliſh glue; and this being done, the whole is ſet in a preſs to dry, planed over, and poliſhed with the ſkin of the ſea-dog, wax, and ſhave-graſs, as in ſimple vaneering, and the fine branches and more delicate parts of the figures are touched up and finiſhed with a graver.

MARQUIS, a title of honour, next in dignity to that of duke, firſt given to thoſe who commanded the marches, that is, the borders and frontiers of countries.

Marquiſſes were not known in England till king Richard II. in the year 1337, created his great favourite, Robert Vere, the earl of Oxford, marquis of Dublin; ſince which time there have been many creations of this ſort, though at preſent there is but one Engliſh and two Scotch marquiſſes. The manner of creating a marquis differs in nothing from that of a duke, except the difference of the titles, and the marquis's being conducted by a marquis and an earl, while a duke is led by a duke and a marquis; he is alſo girt with a ſword, has a gold verge put into his hand, and his robe or mantle is the ſame as thoſe of a duke, with only this difference, that a duke's mantle has four guards of ermine, and a marquis's only three and a half. The title given him, in the ſtyle of the heralds, is moſt noble and potent prince. His cap is the ſame as a duke's, and the difference between their coronets conſiſts in the duke's being adorned with only flowers or leaves, while the marquis's has flowers and pyramids with pearls on them, intermixed, to ſhew that he is a degree between a duke and an earl.

MARRIAGE, a contract both civil and religious, between a man and a woman, by which they engage to live together in mutual love and friendſhip, for the ends of procreation, &c.

MARROW, *Medulla*, in anatomy, has various ſignifications: the white ſubſtance of the brain, in contradiſtinction from the cortical part, is called the ſpinal marrow; but, properly, marrow denotes that ſoft oleaginous ſubſtance contained in the cavity of the bones.

Every bone in the body, of any conſiderable thickneſs, has either a large cavity, or is full of little cells; in both the one and the other is marrow contained in proper veſicles that open into one another.

In the larger bones this fine oil, by the gentle heat of the body, enters ſome narrow paſſages, which lead to certain fine canals excavated in the ſubſtance of the bone; and from theſe other croſs paſſages, not directly oppoſite to the former, carry the marrow ſtill farther into more longitudinal canals placed nearer the ſurface of the bone. All this contrivance is, that the marrow may ſupple the fibres of the bones, and render them leſs apt to break.

By latter obſervations, blood-veſſels have been found in the bones, ſo that they are nouriſhed in the ſame manner as the other parts of the body. Beſides, we find that many bones grow, and yet have no marrow in them, as the horns of deer, lobſters claws, &c.

All marrows are mollifying, rarefying, give relief by friction under laſſitudes, and incarnate ulcers.

MARRUBIUM, hoar-hound and baſtard dittany, in botany, a genus of plants, with a monopetalous ringent flower, the upper lip of which is erect, ſemibifid, and acute, and the under lip reflex and ſemitrifid: the ſeeds are four, and contained in the cup.

Hoar-hound is reputed attenuant and reſolvent, and accordingly preſcribed in moiſt aſthmas, and in all diſeaſes of the breaſt and lungs. Formerly there uſed to be kept a compound ſyrup of it in the ſhops, but it is now out of uſe.

MARS, in aſtronomy, one of the ſuperior planets, moving round the ſun in an orbit between thoſe of the earth and Jupiter. See the article PLANET.

For the diameter of this planet, and its mean diſtance from the ſun, ſee the articles DIAMETER and DISTANCE.

The character of this planet is ♂; the excentricity of its orbit is 141, ſuppoſing the diſtance of the earth from the ſun 1000 equal parts; the inclination of its orbit to that of the earth is 1° 51′; the periodical time in which it performs its revolution round the ſun, is 686 days, 23 hours, 27′ 30″; its revolution round its own axis 24 hours, 40′; and its parallax, 30″. See the articles CHARACTER, EXCENTRICITY, &c.

In the achronical riſing of this planet, that is, when it is in oppoſition to the ſun, its is found twice as near the earth as the ſun, which is a phænomenon that has greatly diſcredited the Ptolemaic hypotheſis. This planet, as well as the reſt, borrows its light from the ſun, and has its increaſe and decreaſe of light like the moon; and it may be ſeen almoſt biſſected when in its quadratures with the ſun, or in its perigæon; but is never corniculated or falcated, as the inferior planets.

Dr. Hook, in 1665, obſerved ſeveral ſpots in this planet, which having a motion, he concluded the planet to have a turbinated motion round its center. In 1666, M. Caſſini obſerved ſeveral ſpots in the two hemiſpheres of Mars, which, by continuing his different obſervations very diligently, he found to move by little and little from eaſt to weſt, and to return in the ſpace of 24 hours 40′ to their former ſituation. Whence both the motion and period or natural day of that planet were determined. See the article MACULÆ.

Mars always appears with a ruddy troubled light, whence we conclude that it is encompaſſed with a thick cloudy atmoſphere, which by diſturbing the rays of light in their paſſage and re-paſſage through it, occaſion that appearance. Beſides the ruddy colour of Mars, we have another argument of his being encompaſſed with an atmoſphere, and it is this, that when any of the fixed ſtars are ſeen near his body, they appear extremely obſcured and almoſt extinct; and if this be the caſe, a ſpectator in Mars would ſcarce ever ſee Mercury, unleſs perhaps in the ſun at the time of conjunction, when Mercury paſſes over his diſk, as he ſometimes appears to us in form of a ſpot. An eye in Mars will ſee Venus at about the ſame diſtance from the ſun as Mercury appears to us, and the earth about the ſame diſtance from the ſun that Venus appears to us; and when the earth is found in conjunction with and very near the ſun, the eye in Mars will ſee the earth horned or falcated, and its attendant, the moon, of the ſame figure, and at its utmoſt diſtance from the earth

earth not above fifteen minutes of a degree: and as this planet's diſtance from the ſun is to the diſtance of the earth and ſun as 1 ½ to 1; therefore a ſpectator in Mars would ſee the ſun's diameter leſs by one third than it appears to us, and conſequently the degree of light and heat which Mars receives from the ſun, is leſs by one third than that received by the earth; this proportion will, however, admit of a ſenſible variation, on account of the great excentricity of this planet.

Though the period or year of this planet, as has been already obſerved, is nearly twice as long as ours, and his natural day, or the time in which the ſun appears above his horizon, ſetting aſide the conſideration of twilight, is almoſt every where equal to his night; yet it appears that in one and the ſame place, on his ſurface, there will be but very little variety of ſeaſons, or ſcarce any difference of ſummer and winter: and the reaſon is, that the axis of his diurnal rotation is nearly at right angles with the plane of his orbit. It will be found, notwithſtanding, that places ſituated in different latitudes, that is, at different diſtances from his equator, will have very different degrees of heat, on account of the different inclination of the ſun's rays to the horizon, as it is with us when the ſun is in the equinoxes.

From this conſideration Dr. Gregory endeavours to account for the appearance of the faſciæ in Mars, which are certain ſwaths or fillets ſeen in this planet, and poſited parallel to his equator; for as among us, the ſame climate has at different ſeaſons very unequal degrees of heat, but as in Mars it is otherwiſe, the ſame parallel having always a pretty equable degree of heat, it follows, that theſe ſpots may probably be formed in Mars, or in his atmoſphere, as ſnow and clouds are in ours, viz. by the conſtant different intentions of heat and cold in the different parallels, and ſo come to be extended in circles or belts parallel to his equator, or the circle of his diurnal motion. And this ſame principle may, perhaps, ſolve the phœnomenon of Jupiter's belts, that planet, like Mars, having a perpetual equinox. See the article JUPITER.

MARS, among chemiſts, denotes iron, as being ſuppoſed to be under the influence of that planet. See the article IRON.

Crocus of MARS. See CROCUS MARTIS.

MARINE implies in general the whole navy of a kingdom or ſtate, comprehending all the royal dock-yards, and the officers, artificers, ſeamen, ſoldiers, &c. employed therein, as well as the ſhipping employed by the merchants for military or commercial purpoſes, together with whatever relates to navigation, ſhip-building, ſailors, and marines.

The hiſtory of the marine affairs of any one ſtate is a very comprehenſive ſubject, much more that of all nations. Thoſe who would be informed of the maritime affairs of Great Britain, and the figure it has made at ſea in all ages, may find abundance of curious matter in Selden's *Mare Clauſum*, and from his time to ours, we may trace a ſeries of facts in Lediard's and Burchet's Naval Hiſtory; but above all in the Lives of the Admirals by the accurate and judicious Dr. Campbell.

Not only the preſervation of that ſhare of commerce we at preſent poſſeſs, but its future advancement, and even the very being of Britain, as an independent empire, and a free people, depend no leſs on the good condition and the wiſe regulation of our affairs of the marine, than on the ſuperiority of its naval power. The Delphian oracle being conſulted by the Athenians, on the formidable armament and innumerable forces of Xerxes, returned for anſwer, "that they muſt ſeek their ſafety in wooden walls." To which we may affirm, that whenever this nation in particular has recourſe to her floating bulwarks for her ſecurity and defence, ſhe will find ſtrength, wealth, and glory, to be the happy and infallible conſequence.

That the legiſlature has ever been attentive to this great and important object will appear from the following account of the laws that have been enacted relating to the affairs of the Britiſh marine.

So early as 5 Rich. II. c. 3. it was enacted, that none of the king's ſubjects ſhould bring in or carry out any merchandize, but in Engliſh ſhips, on pain of forfeiting all the merchandize otherwiſe conveyed, or the value thereof; but 6 Rich. II. ordains, that the above ſtatute ſhall only take place where able ſhips belonging to the king's ſubjects are to be found; for where they are not to be had, the merchants are allowed to hire other ſhips. By 4 Hen. VII. c. 10. it was enacted, that no Gaſcoign or Guienne-wines, &c. ſhould be imported into this realm but in Engliſh veſſels: and that none ſhould freight any merchandize in any ſtranger's ſhip, if he could have ſufficient freight in a denizen's ſhip, under the penalty of forfeiting all merchandize not thus ſhipped, to be divided between the king and the ſeizer: but this act, ſo far as it related to the above wines, was repealed by the ſtatute 32 Hen. VIII. c. 14. and a rate was ordered of what ſhould be paid for the freight of the ſeveral ſorts of merchandize in ſhips, from the port of London to other places, and from thence to London. By 1 Eliz. c. 13. it was enacted, that if the owner of any merchandize ſhould, in the time of peace, embark or unload any part thereof, (maſts, pitch, tar, and corn, only excepted) out of, or into any foreign ſhip, he ſhould pay cuſtom as an alien.

By the act of navigation, 12 Car. II. c. 18. it is enacted, that no goods ſhall be imported into, or exported out of, any territories belonging to, or that may hereafter belong to his majeſty, his heirs and ſucceſſors, in Aſia, Africa, or America, in any other ſhips beſides ſuch as belong to the people of England, Ireland, Wales, or the town of Berwick upon Tweed, and whereof the maſter and three-fourths of the mariners are Engliſh, on pain of forfeiting both the ſhip and lading, one third part to the king, another to the governor of the country where ſuch default ſhall be, if ſeized there, otherwiſe that third alſo to the king, and the other third to him that will ſeize or ſue for the ſame. And commanders at ſea, having the king's commiſſion, are to bring in as prize all ſuch ſhips, and on their being condemned, one moiety is to be for the uſe of ſuch commanders and their companies, and the other moiety to the king. No goods of the growth or manufacture of Muſcovy, or of the produce of the Turkiſh empire, ſhall be imported into England, Ireland, &c. in any ſhip or veſſel not Engliſh built, or not belonging to the people of England, Ireland, &c. and navigated as aforeſaid; except veſſels built at the place from whence the goods came, or of ſuch port where they can only be, and uſually are ſhipped, on pain of forfeiting the ſhip and goods; and all wines of the growth of France and Germany, and divers goods and merchandize from Spain, Portugal, Ruſſia, &c. which ſhall be imported into the places aforeſaid, in any other ſhip than what doth belong to England, Ireland, &c. and are navigated as aforeſaid, ſhall be deemed aliens goods, and pay accordingly. And no foreign-built veſſel ſhall paſs as a ſhip belonging to England, Ireland, Wales, &c. till the owner makes it appear to the chief officer of the cuſtoms, in the port next to the place of his abode, that he is not an alien, and take an oath that it was *bona fide* bought of ſuch perſons, expreſſing the ſum given, and the time and place when and where, &c. and that no foreigner has a ſhare in it. Alſo none ſhall load in any bottom, if ſtrangers are owners, part-owners, or maſter, and of which three-fourths of the mariners at leaſt are not Engliſh, any goods whatſoever from one port or creek of England, Ireland, Wales, Guernſey, Jerſey, or the town of Berwick, to another port of the ſame, on pain of forfeiting ſuch goods and veſſel.

The 22 and 23 Car. II. c. 11. ordains, that where any goods ſhall be laden on board any Engliſh ſhip of the burden of two hundred tons, or upwards, and mounted with ſixteen guns, or more, if the maſter yields up ſuch ſhip or goods to any Turkiſh veſſel, or any pirate, without fighting, upon proof thereof in the admiralty, he ſhall be incapable of taking charge of any Engliſh veſſel: and maſters of Engliſh ſhips, though not of that burden, nor mounted as aforeſaid, that ſhall yield without fighting to a Turkiſh ſhip or pirate, that has not at leaſt double the number of guns, ſhall be liable to the penalties of this act. If any inferior officers or mariners of a ſhip, ſhall refuſe to fight when commanded, or utter words to diſcourage others, they ſhall loſe all their wages due, and be impriſoned not exceeding ſix months; and mariners laying violent hands on their commanders, to hinder them

from fighting in defence of their ſhips, ſhall ſuffer death as felons. When any Engliſh ſhip ſhall have been defended by fight, and brought to her port, in which fighting any of her men have been wounded or ſlain, the judge of the admiralty, or his ſurrogate, &c. where ſhe ſhall arrive, upon the petition of the maſter and ſeamen, may call ſo many as he ſhall be informed are the adventurers and owners, and by adviſing with them, levy upon the reſpective owners ſuch ſums as he himſelf, and the major part of them preſent, ſhall judge reaſonable, not exceeding two per cent. of the ſhip and goods; which money ſhall be diſtributed among the maſter, officers, and ſeamen, or the widows and children of the ſlain, according to the direction of the judge, with the approbation of three or more of the adventurers. By the 5th and 6th of Will. and Mary, c. 24. every perſon who ſhall build, or cauſe to be built, any ſhip of three decks, containing 450 tons, and mounted with thirty-two pieces of ordnance, having ammunition, &c. proportionable, ſhall for the firſt three voyages which the ſaid ſhip ſhall make to any foreign parts, receive a tenth of the cuſtoms called the ſubſidy of tonnage and poundage, payable for merchandize exported and imported in ſuch ſhips; but if after the end of the three firſt voyages, ſhips ſo built, ſhall be altered ſo as to become leſs defenſible than they were at firſt, then they ſhall be forfeited and loſt.

By 2 Ann. c. 9. owners of ſhips might navigate during the war with France, with maſters, and only one half of the mariners Engliſh: and by 3 and 4 Ann. c. 13. any ſhips might be navigated by foreign ſeamen; and foreigners ſerving on board any Engliſh ſhip for two years, were to be deemed natural-born ſubjects, &c.

By 4 Geo. I. c. 12. and 11 Geo. I. c. 29. if any officer or mariner belonging to any ſhip or veſſel, ſhall wilfully caſt away, burn, or deſtroy the ſhip to which he belongeth, or in any-wiſe direct or procure the ſame to be done, with intent to prejudice a perſon that ſhall have granted any inſurance thereon, or any merchant who ſhall load goods therein, or any owner of ſuch veſſel, the perſons offending ſhall on conviction be adjudged guilty of felony without benefit of clergy.

The 5th of Geo. II. c. 20. enacts, that no commander of any ſhip outward-bound ſhall receive on board any gun-powder, either as merchandize or ſtores for the voyage, except for his majeſty's ſervice, before ſuch ſhip ſhall be at Blackwall, in the river Thames; and all maſters of ſhips coming into the river, ſhall put on ſhore all powder either before the arrival of their ſhips at the ſaid place, or within twenty-four hours after they come to anchor there, upon pain of forfeiting 5 l. for every 50 pounds weight of gun-powder on board, and in the like proportion for a leſs quantity. And no guns ſhall be kept loaded with ſhot in merchant ſhips between London bridge and Blackwall, or fired before the riſing, or after the ſetting of the ſun, under the penalty of 5 l. and for every gun ſo fired, 10 s. And if any pitch, tar, roſin, or other combuſtible matter ſhall be heated or melted by fire in any ſhips, every perſon ſo offending, ſhall, for every offence, forfeit 5 l. And ſhips are liable to be ſearched by an elder brother, appointed by the maſter, wardens, and aſſiſtants of the Trinity-houſe at Deptford. In caſe any ſhip ſhall be moored in the mouth or any other part of St. Saviour's dock, except ſuch ſhips as ſhall be loading or delivering their cargoes, and others, not exceeding two at a time, that ſhall lie at ſhipwright-yard, at the north-weſt corner of the ſaid dock, during the time they ſhall be repairing, the maſter of ſuch ſhip ſhall forfeit 20 s. for every day ſhe ſhall continue to be laid up and moored.

By 6 Geo. II. c. 29. maſters of ſhips lying in the river Thames who have occaſion for ballaſt, ſhall pay 1 s. per ton colliers, other ſhips 1 s. 3 d. and foreign ſhips 1 s. 7 d. per ton, to the corporation of the Trinity-houſe at Deptford; who ſhall pay ballaſt-men 9 d. a ton, for raiſing and carrying it, &c. and it ſhall be lawful for any maſter of a ſhip to appoint two perſons to go on board any lighter bringing ballaſt to ſuch ſhip, to inſpect the marks thereof; and every ballaſt-man ſhall immediately before the delivery of ballaſt to any ſhip, trim ſuch lighter, ſo as to make it ſwim at equal marks at the ſtem and ſtern, and pump all the water out, &c. and the maſter, wardens, and aſſiſtants of the Trinity-houſe, are to make good to the maſter, the quantity or value of the ballaſt which ſhall be found deficient, or forfeit 50 l. one moiety to the poor, and the other to the perſon ſuing for it. The 7th of Geo. II. c. 15. ordains, that no owners of ſhips ſhall be liable to any loſs by reaſon of embezzlement by the maſter or mariners, of any goods or merchandize ſhipped on board, or for any act done by them, without the privity or knowledge of ſuch owners, further than the value of the ſhip, and amount of the freight during the voyage, in which ſuch embezzlement of the maſter or mariners ſhall be committed; and if ſeveral perſons ſhall ſuffer damage by the means aforeſaid, and the value of the ſhip and cargo ſhould not be ſufficient to make compenſation; then the freighters ſhall receive ſatisfaction in average, in proportion to their reſpective loſſes, to be aſcertained on a bill in equity, exhibited for a diſcovery thereof, and of the value of ſuch ſhip and freight. But nothing in this act ſhall diſcharge any remedy, which any perſon may have againſt the maſter and mariners, in reſpect of an embezzlement. See the articles FREIGHT, INSURANCE, &c.

MARINES, or MARINE FORCES, a body of ſoldiers raiſed for the ſea-ſervice, and trained to fight either in a naval engagement, or in an action aſhore.

The great ſervice of this uſeful corps was manifeſted frequently in the courſe of the late war, particularly at the ſiege of Belleiſle, where they acquired a great character, although lately raiſed and hardly exerciſed in military diſcipline. At ſea they are incorporated with the ſhip's crew, of which they make a part, and many of them learn in a ſhort time to be excellent ſeamen, to which their officers are ordered by the admiralty to encourage them, although no ſea-officer is to order them to go aloft againſt their inclination. In a ſea-fight their ſmall arms are of very great advantage in ſcouring the decks of the enemy; and when they have been long enough at ſea to ſtand firm when the ſhip rocks, they muſt be infinitely preferable to ſeamen if the enemy attempts to board, by fraiſing a battalion with their fixed bayonets to oppoſe him. See the article BOARDING.

The marine forces of Great-Britain in the time of peace are ſtationed in three diviſions; one of which is quartered at Chatham, one at Portſmouth, and another at Plymouth. By a late regulation they are ordered to do duty at the ſeveral dock-yards of thoſe ports, to prevent embezzlement of the king's ſtores, for which a captain's guard mounts every day; which certainly requires great vigilance, as ſo many abuſes of this kind have been committed, that many of the inhabitants, who have been long uſed to an infamous traffic of this kind, expect theſe conveyances at certain periods, as their due, and of courſe reſent this regulation in the higheſt degree as an infringement of their liberty as Engliſhmen.

MARSHAL, in its primary ſignification, means an officer who has the command or care of horſes; but it is now applied to officers who have very different employments, as earl-marſhal, knight-marſhal, or marſhal of the king's houſe, &c.

MARSHAL, or MARESCHAL, *of France*, an officer of the greateſt dignity in the French armies. When two or more mareſchals are in the army, the eldeſt commands.

MARSHALLING a coat, in heraldry, is the diſpoſal of ſeveral coats of arms belonging to diſtinct families, in one and the ſame eſcutcheon or ſhield, together with their orhaments, parts, and appurtenances.

MARSHMALLOW, *Althæa*, in botany and medicine. See ALTHÆA.

MARSHY LANDS, thoſe liable to be overflowed by the ſea, or large rivers, for the draining of which, ſee the articles DITCH, DRAIN, &c.

MARSUPIALIS MUSCULUS, in anatomy, a muſcle otherwiſe called the internal obturator. See OBTURATOR.

MARTIAL, among phyſicians, an appellation given to the preparations of iron.

MARTIAL LAW is the law of war, which entirely depends on the arbitrary power of the prince, or of thoſe to whom he has delegated it: for though the king can make no laws in time of peace without the conſent of parliament, yet in time of war he uſes an abſolute power over the army.

MARTIN,

MARTIN, *Martes*, in zoology, a ſpecies of muſtela, of a blackiſh brown colour, and with a pale throat: it is about the ſize of the common cat, but more ſlender. See MUSTELA.

MARTIN is alſo the name of a bird of the hirundo kind, of a black colour, and with the throat white.

MARTINGALE, in the manege, a thong of leather faſtened to one end of the girths under the belly of a horſe, and at the other end to the muſs-roll, to keep him from rearing.

MARTLETS, in heraldry, little birds repreſented without feet, and uſed as a difference or mark of diſtinction for younger brothers, to put them in mind that they are to truſt to the wings of virtue and merit, in order to raiſe themſelves, and not to their feet, they having little land to ſet their feet on.

MARTYR, in the Chriſtian ſenſe of the word, is one who lays down his life for the Goſpel, or ſuffers death for the ſake of his religion.

The feſtivals of the martyrs are of very ancient date in the Chriſtian church, and may be carried back at leaſt till the time of Polycarp, who ſuffered martyrdom about the year of Chriſt 168. On theſe days the Chriſtians met at the graves of the martyrs, and offered prayers and thankſgivings to God for the examples they had afforded them; they celebrated the euchariſt, and gave alms to the poor; which, together with a panegyrical oration or ſermon, and reading the acts of the martyrs, were the ſpiritual exerciſes of theſe anniverſaries.

MARTYROLOGY, in the church of Rome, is a catalogue or liſt of martyrs, including the hiſtory of their lives and ſufferings for the ſake of religion.

MARVEL *of Peru*, in botany, a name uſed by ſome for jalap. See JALAP.

MARUM SYRIACUM, Syrian herb-maſtich, in botany, a low ſhrubby plant, with ſmall oval leaves, pointed at each end, ſet in pairs, without pedicles, of a dilute green colour above, and hoary underneath: in their boſoms appear ſolitary, purple, labiated flowers, wanting the upper lip; the lower lip is divided into five ſegments, the middleſt of which is larger than the reſt, and hollowed like a ſpoon; each flower is followed by four roundiſh ſeeds incloſed in the cup. It is ſaid to be a native of Syria, and of one of the Hieres iſlands, on the coaſt of Provence: in our climate it does not well bear ſevere winters without ſhelter.

The leaves of marum have a bitteriſh, aromatic, very pungent taſte; and when rubbed a little, yield a quick piercing ſmell, which provokes ſneezing. They have been chiefly made uſe of as an ingredient in ſternutatory powders, though, from their ſenſible qualities, they promiſe to be applicable to more important purpoſes, and to have no ill title to the ſtimulating, attenuating, deobſtruent, antiſeptic virtues aſcribed to them by Wedelius in a diſſertation on this plant: they ſeem particularly well adapted as an ingredient in the volatile oily aromatic ſpirits with which their agreeable pungency in a great degree coincides.

The marum loſes but little of its pungency on being dried, and in this reſpect it differs remarkably from many other acrid herbs, as thoſe called antiſcorbutic.

MARY MAGDALEN's DAY, a feſtival of the Romiſh church, obſerved on the twenty-ſecond of July.

MARYGOLD, or MARSH-MARYGOLD, a plant called by botaniſts caltha. See CALTHA.

Corn MARYGOLD, chryſanthemum. See the article CHRYSANTHEMUM.

French MARYGOLD, in botany, tagetes. See TAGETES.

MASCULINE, or MASCULINE-GENDER, among grammarians, that belonging to the male. See GENDER.

MASON, a perſon employed under the direction of an architect, in the raiſing of a ſtone-building.

The chief buſineſs of a maſon is to make the mortar, raiſe the walls from the foundation to the top, with the neceſſary retreats and perpendiculars; to form the vaults, and employ the ſtones as delivered to him. When the ſtones are large, the buſineſs of hewing or cutting them belongs to the ſtone-cutters, though theſe are frequently confounded with maſons: the ornaments of ſculpture are performed by carvers in ſtone or ſculptors. The tools or implements principally uſed by them are the ſquare, level, plumb-line, bevel, compaſs, hammer, chiſſel, mallet, ſaw, trowel, &c. See SQUARE, &c.

MASONRY, in general, a branch of architecture, conſiſting in the art of hewing or ſquaring ſtones, and cutting them level or perpendicular, for the uſes of building; but in a more limited ſenſe, maſonry is the art of aſſembling and joining ſtones together with mortar.

Hence ariſes as many different kinds of maſonry, as there are different forms and manners for laying or joining ſtones. Vitruvius mentions ſeveral kinds of maſonry uſed among the ancients, three of hewed ſtone, viz. that in form of a net, that in binding, and that called the Greek maſonry; and three of unhewed ſtones, viz. that of an equal courſe, that of an unequal courſe, and that filled up in the middle; and the ſeventh was a compoſition of all the reſt, each in their order.

Net-maſonry, called by Vitruvius reticulatum, from its reſemblance to the meſhes of a net, conſiſts of ſtones ſquared in their courſes, and ſo diſpoſed as that their joints go obliquely; and their diagonals are the one perpendicular, and the other level. This is the moſt agreeable maſonry to the eye, but it is very apt to crack. See plate LXXXII. *fig.* 8.

Bound maſonry, that in which the ſtones were placed one over another, like tiles; the joints of their beds being level, and the mounters perpendicular, ſo that the joint that mounts and ſeparates two ſtones, always falls directly over the middle of the ſtone below. This is leſs beautiful than the net-work; but it is more ſolid and durable. See *fig.* 9.

Greek maſonry, according to Vitruvius, is that where after we have laid two ſtones, each of which makes a courſe, another is laid at the end, which makes two courſes, and the ſame order is obſerved throughout the building; this may be called double binding, in regard the binding is not only of ſtones of the ſame courſe with one another, but likewiſe of one courſe with another courſe. See *fig.* 10.

Maſonry by equal courſes, called by the ancients iſodomum, differs in nothing from the bound maſonry, but only in this, that its ſtones are not hewn. See *fig.* 11.

Maſonry by unequal courſes, called pſeudiſodomum, is alſo made of unhewed ſtones, and laid in bound work; but then they are not of the ſame thickneſs, nor is there any equality obſerved, excepting in the ſeveral courſes; the courſes themſelves being unequal to each other. See *fig.* 12.

Maſonry filled up in the middle, called by the ancients emplection, is likewiſe made of unhewed ſtones, and by courſes; but the ſtones are only ſet in order as to the courſes.

Fig. 13. A, the courſes; B, the parts filled up; C, a coat of plaſter.

Compound maſonry is of Vitruvius's propoſing, ſo called, as being formed of all the reſt. In this the courſes are of hewed ſtone; and the middle being left void, is filled up with mortar and pebbles thrown in together: after this the ſtones of one courſe are bound to thoſe of another courſe with cramp irons faſtened with melted lead.

Fig. 14. E, the ſtones cramped; F, the cramps; G, the middle part filled up.

Fig. 15. repreſents another ſort of compound maſonry, the middle of which is ſtone, and the edges boards.

All the kinds of maſonry now in uſe may be reduced to theſe five, viz. bound maſonry; that of brick-work, where the bodies and projectures of the ſtones incloſe ſquare ſpaces or pannels, &c. ſet with bricks; that de moilon, or ſmall work, where the courſes are equal, well ſquared, and their edges or beds ruſticated; that where the courſes are unequal; and that filled up in the middle with little ſtones and mortar.

MASQUE, or MASK, a cover for the face, with ſuitable apertures for the eyes and mouth.

MASQUES, in architecture, denotes certain groteſque

faces, uſed to fill vacant places, as friezes, pannels of doors, keys of arches, &c.

MASQUERADE, an aſſembly of perſons maſked, and dreſſed in peculiar habits, meeting to dance and divert themſelves.

MASS, *Miſſa*, in the church of Rome, the office or prayers uſed at the celebration of the euchariſt; or in other words, conſecrating the bread and wine into the body and blood of Chriſt, and offering them ſo tranſubſtantiated, as an expiatory ſacrifice for the quick and the dead. As the maſs is in general believed to be a repreſentation of the paſſion of our bleſſed Saviour, ſo every action of the prieſt, and every particular part of the ſervice, is ſuppoſed to allude to the particular circumſtances of his paſſion and death.

MASSALIANS, a ſet of enthuſiaſts who ſprang up about the year 361, in the reign of the emperor Conſtantius, who maintained that men have two ſouls, a celeſtial and a diabolical, and that the latter is driven out by prayer. They pretended to prophecy, and affirmed that they could ſee the Trinity with their corporeal eyes; and believed that the Holy Ghoſt deſcended viſibly upon them, eſpecially at the time of their ordination, when they trod the devil under foot, and danced upon him.

MASSETER, in anatomy, a muſcle which has its origin in the lower and interior part of the jugum, and its end at the external ſuperficies of the angle of the jaw. The ductus Stenonianus, or ſalival duct of Steno, paſſes over this muſcle.

MASSIVE, among builders, an epithet given to whatever is too heavy and ſolid: thus a maſſive column is one too ſhort and thick for the order whoſe capital it bears; and a maſſive wall is one whoſe openings or lights are too ſmall in proportion.

MASSORA, in matters of literature, a critical work, containing remarks on the verſes, words, letters, and vowel-points of the Hebrew text of the Bible; a work more laborious than uſeful, ſuch poor obſervations being beneath the notice of men of learning.

MAST, in ſhip-building, a large ſtrong poſt, or pole, of timber, ſtanding erect in a ſhip to carry ſail, whereby ſhe is enabled to make her progreſs through the ſea.

Among the ancient Grecians every ſhip had ſeveral maſts: we are nevertheleſs informed by Ariſtotle, that at firſt there was only one maſt, which being fixed in the middle of the ſhip, the hole into which the foot of it was inſerted, μεσοδμη, in Latin, *modius*, and in Engliſh, the *ſtep*. The parts of the maſt were theſe: πτερνα, or the foot Λινας; or, according to Athenæus, λινον, or τραχηλον, to which the ſail was fixed. Καρχησιον, the pulley by which the ropes were turned round. Θωρακιον, built in the manner of a turret for ſoldiers to ſtand upon and caſt their darts; above this was a piece of wood, called ἱκριον, the extremity of which was termed πλακατη, on which hung a ribband, called from its continual motion επισειων, turning round with the wind; this is termed in Engliſh, the *vane*.

With regard to the moderns, the maſts of their ſhips generally conſiſt of three pieces, joined together lengthwiſe, viz. the lower-maſt, the top-maſt, and the top-gallant-maſt. The top maſt ſtands at the head of the lower-maſt, and the top-gallant-maſt at the head of the top-maſt in the ſame manner, and either of the two latter can be occaſionally taken down; but the lower-maſt, as it is ſettled on the keel of the ſhip, can only be removed by hoiſting it out or cutting it away.

A little below the head of the lower-maſt is fixed the frame of the top, which reſts upon the hounds of the maſt; through this frame the top-maſt is hoiſted, after which the head of it paſſes through the cap, which is a block of wood with two holes in it, one of which reſts on the head of the lower-maſt, and the other ſerves as above, to keep the top-maſt ſteady. When the top-maſt is thus hoiſted up to its utmoſt extent, and kept ſteady above by the cap, and below by the top-frame, a large bar of wood or iron is thruſt through a ſquare hole in the heel of it, cut for that purpoſe; and this bar extending acroſs the middle of the top-frame, the whole weight of the top-maſt reſts upon it; as does the top-gallant-maſt in the ſame manner at the head of the top-maſt.

As every maſt is compoſed of three pieces, it will be alſo neceſſary to inform our readers that all ſhips, properly ſo called, are furniſhed with three maſts, viz. the main-maſt, the fore-maſt, and mizen-maſt. Thoſe which have only two or one maſt, are not called ſhips by ſeamen, but vary their names according to their method of rigging. Of two maſts, there are ſnows, brigs, bilanders, ketches, buſſes, ſchooners, and hermaphrodites, among the Engliſh. Among the Spaniards and Italians, ſettees, barco-longas, feluccas, &c. Thoſe of one maſt are ſloops, tartans, bean-cods, ſhallops, &c.

In the Britiſh navy, maſts are proportioned to the extreme breadth of the ſhip from out to out.

Proportion for the length of maſts, Anno 1745.

			Guns.
1000 : breadth in feet ::	748 :	main-maſt in yards	100
	756 :		90
	753 :		80
	741 :		70 & 60
	740 :		50
	747 :		44
	760 :		24
1000 : main-maſt ::	895 : 901 :	fore-maſt	100, 90, 80, & all the reſt.
1000 : main-maſt ::	870 866	mizen-maſt	100, 90, 80, & all the reſt.
1000 : main-maſt ::	640 613	bowſprit	100, 90, 80, & all the reſt.
1000 : main-maſt ::	600 : 605 : 613 :	main-top-maſt	100,90,80, 70,60,50, 40, 24.
1000 : main-top-maſt ::	900 : 910 :	fore-top-maſt	100,90,80 all the reſt.
1000 : main-top-maſt ::	710 : 717 :	miz. top-maſt	100,90,80, all the reſt.
1000 : main-top-maſt ::	480 : 508 :	main-top-gallant-maſt	100,90,80, all the reſt.
1000 : fore-top-maſt ::	480 : 505 :	fore-top-gallant maſt	100,90,80, all the reſt.

The proportion for maſting ſhips in the merchants ſervice is generally regulated by the judgment and experience of the commander.

The main and fore-maſt in all ſhips down to 60 guns, one inch diameter to every yard in length.

For 50 and 40 guns, twenty-ſeven twenty-eighths of an inch diameter to one yard in length.

For 24 guns, twelve thirteenths of an inch in diameter to one yard in length.

All top-maſts are nine tenths of an inch in diameter to one yard in length.

The fore-top-maſt as big as the main-top-maſt.

The top-gallant-maſt one inch to a yard.

The mizen-maſt $\frac{15}{22}$ of an inch to one yard in length.

The mizen-top-maſt five-ſixths of an inch to one yard in length.

The bowſprit an inch and an half to one yard.

The jib-boom ſeven-eighths of an inch to a yard. See the articles BOWSPRIT and JIB-BOOM.

MASTER, *Magiſter*, in general, is a title of authority; as the grand maſter of Malta, the maſter of St. Lazarus, &c.

MASTER *of a Ship of War*, an officer who has the charge of navigating the ſhip from port to port, under the direction of the captain; the management and diſpoſition of the ſails, the conducting the ſhip in all extremities of danger, and directing her motions in the time of action more particularly belongs to him, as alſo to ſuperintend the proviſions, and ſee that none are permitted to come aboard but ſuch as are wholeſome and ſweet: he is alſo to take care that they are ſafely ſtowed by his mates and quarter-maſters; theſe are alſo employed to ſuperintend the navigation when he is off the deck, and to aſſiſt wherever his duty is concerned.

MASTER *of a Merchant Ship*, the officer who commands and directs her courſe, manages her lading, and all other affairs.

MASTER *at Arms*, in the marine, an officer whoſe buſineſs it is to confine and plant centries over the priſoners

in a ſhip of war; to obſerve that all the lights and fire are put out when the evening gun fires, only ſuch as are allowed by proper authority, or which are under the inſpection of centries: he is alſo to attend the ſide when any boats come aboard, and ſearch carefully that no ſpirituous liquors are brought into the ſhip, but what are permitted by the commanding officer. He is likewiſe to teach the ſeamen the exerciſe of the ſmall arms, to which they have generally a great averſion; for this purpoſe, in large ſhips, the maſter at arms has ſeveral corporals under him to aſſiſt in his office, and relieve the centries and each other. See the article CORPORAL.

MASTER *Attendant*, in the king's dock-yards, an officer whoſe duty it is to obſerve that all the ſhips, which are laid up, or ſaid to be in ordinary, are properly moored, cleaned, and kept in order; for which purpoſe he is often to viſit and examine them; he alſo attends the muſters in the dock-yard, to obſerve that all the men regiſtered on the books do their duty: he has likewiſe the charge of the moorings, which are fixed in the river or harbour where he reſides, and theſe he is always to keep in good repair, that they may be ready to moor the ſhips of war when neceſſary, which employment he muſt alſo ſee ſecurely performed: he removes the ſhips from one place to another in the harbour, and pilots them into and out of the docks, &c. See the articles DOCK-YARD, ORDINARY, and MOORINGS.

MASTER *Shipwright*. See the article SHIPWRIGHT.

MASTER *of Arts* is the firſt degree taken up in foreign univerſities, and for the moſt part in thoſe of Scotland; but the ſecond in Oxford and Cambridge; candidates not being admitted to it till they have ſtudied ſeven years in the univerſity. See the article DEGREE.

MASTERS *in Chancery*, in ordinary, of which there are twelve, the maſter of the rolls being chief, are uſually choſen out of the barriſters of the common law, and ſit in chancery, or at the rolls, as aſſiſtants to the lord chancellor and maſter of the rolls.

MASTER-GUNNER. See GUNNER.

MASTER *of the Horſe*, a great officer of the crown, who orders all matters relating to the king's ſtables, races, breed of horſes; and commands the equerries and all the other officers and tradeſmen employed in the king's ſtables. His coaches, horſes, and attendants, are the king's, and bear the king's arms and livery.

MASTER *of the Ordnance*, a great officer who has the chief command of the king's ordnance and artillery.

MASTER *of the Revels*, an officer who orders all things relating to the performance of plays, maſks, balls, &c. at court.

MASTER *of the Rolls*, a patent officer for life, who has the cuſtody of the rolls of parliament and patents which paſs the great ſeal, and of the records of chancery, as alſo commiſſions, deeds, recognizances, which, being made of rolls of parchment, gave riſe to the name.

MASTERWORT, in botany. See the article IMPERATORIA.

MASTICH, in the materia medica, a concrete reſin, obtained in the iſland Chio from the Lentiſk tree, brought over in ſmall yelloviſh tranſparent grains or tears. From tranſverſe inciſions made in the bark of the tree, about the beginning of Auguſt, the reſin exudes in drops, which running down, and concreting on the ground, are thence ſwept up. The tree is raiſed alſo in ſeveral parts of Europe; but no reſin has been obſerved to iſſue from it in theſe climates; nor do all the trees of this ſpecies in the iſland Chio itſelf, afford this commodity. See the article LENTISCUS.

This reſin has a light agreeable ſmell, eſpecially when rubbed or heated: in chewing, it firſt crumbles, ſoon after ſticks together, and becomes ſoft and white, like wax, without impreſſing any conſiderable taſte.

Maſtich is recommended, in doſes of from half a ſcruple to half a dram, as a mild corroborant and reſtringent, in old coughs, hemoptyſes, diarrhœas, weakneſs of the ſtomach, &c. It is given either in ſubſtance, divided by other materials; or diſſolved in ſpirit, and mixed with ſyrups; or diſſolved in water into an emulſion by the intervention of gum arabic or almonds: the decoctions of it in water, which ſome have directed, have little or nothing of the virtue of the maſtich. It is ſaid that this reſin is commonly employed as a maſticatory in Chio, and among the Turkiſh women, for ſweetening the breath, and ſtrengthening the gums and teeth; and that when thus uſed, by procuring a copious excretion of ſaliva, it proves ſerviceable in catarrhous diſorders.

MASTICATION, *Maſticatio*, in medicine, the action of chewing, or of agitating the ſolid parts of our food between the teeth, by means of the motion of the jaws, the tongue, and the lips, whereby it is broken into ſmall pieces, impregnated with ſaliva, and ſo fitted for deglutition, and a more eaſy digeſtion.

MASTICATORIES, in medicine, ſuch remedies as are taken in at the mouth; and chewed in order to promote the evacuation of the ſalival humour, as tobacco, ginger, pepper, ſage, roſemary, thyme, maſtich, &c.

MASTIGADOUR, MASTICADOUR, or SLABBERING BIT, in the manege, a ſnaffle of iron, all ſmooth, and of a piece, guarded with paternoſters, and compoſed of the halfs of great rings, made into demi-ovals, of unequal bigneſs; the leſſer being incloſed within the greater, which ought to be about half a foot high. See the article BIT.

MASTOIDES, in anatomy, the ſame with mammillaris; being applied to ſuch proceſſes in the body as have the appearance of breaſts or dugs, ariſing in a broad baſis, and terminating in an obtuſe top. Maſtoides is ſometimes applied to the muſcle which ſtoops the head, proceeding from the neck-bone and breaſt-bone, and terminating in the proceſs of the mammiformis.

MAT, among ſailors, a ſort of web or texture, formed of a variety of foxes, each of which conſiſts of a certain number of rope-yarns twiſted together; the foxes are conſequently larger or ſmaller, in proportion to the ſize of the mat required.

Mats are uſed to faſten on the outſides of the ſhrouds, and backſtays, to prevent them from being chafed or fretted by the motion of other ropes which bear againſt them; alſo to laſh on ſeveral blockſtrops, &c. for the ſame purpoſe; the largeſt ſort of them are called panches. See the article PANCH.

MATCH, a kind of rope ſlightly twiſted, and prepared to retain fire for the uſes of the artillery, mines, fireworks, &c.

It is made of hempen tow, ſpun on the wheel like cord, but very ſlack; and is compoſed of three twiſts, which are afterwards again covered with tow, ſo that the twiſts do not appear: laſtly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole be conſumed: the hardeſt and drieſt match is generally the beſt.

MATCHING, in the wine-trade, the preparing veſſels to preſerve wines and other liquors, without their growing ſour or vapid. The method of doing it, as directed by Dr. Shaw, is as follows: melt brimſtone in an iron ladle, and when thoroughly melted, dip into it ſlips of coarſe linnen-cloth; take theſe out, and let them cool: this the wine-coopers call a match; take one of theſe matches, ſet one end of it on fire, and put it into the bung-hole of a caſk; ſtop it looſely, and thus ſuffer the match to burn nearly out: then drive in the bung tight, and ſet the caſk aſide for an hour or two. At the end of this time examine the caſk, and you will find that the ſulphur has communicated a violent pungent and ſuffocating ſcent to the caſk, with a conſiderable degree of acidity, which is the gas and acid ſpirit of the ſulphur. The caſk may after this be filled with a ſmall wine, which has ſcarce done its fermentation, and bunging it down tight, it will be kept good and will ſoon clarify: this is a common and very uſeful method, for many poor wines could ſcarce be kept potable even a few months without it.

MATE *of a Ship of War*, an officer under the maſter, whoſe duty it is to obſerve the navigation of the ſhip, and to keep the log ſtrictly marked; to trim the ſails in the fore-part of the ſhip, and to ſuperintend all affairs relating to the cables, moorings, and riding of the ſhip; to command the boats in which proviſions and water are brought to the ſhip, and aſſiſt in ſtowing them after they arrive aboard. See the articles LOG, MASTER, and TRIM.

MATE *of a Merchant Ship*, the officer who commands the ſhip in abſence of the commander, and ſhares the duty with him.

The number of mates both in ſhips of war and merchant-men, is in proportion to the ſize of a ſhip: a firſt rate man of war has ſix mates, and an Eaſt-India-man the ſame number.

MATERIA SUBTILIS denotes a fine ſubtile matter which the Carteſians ſuppoſe to pervade and penetrate freely the pores of all bodies, to fill up all their pores ſo as not to leave the leaſt vacuity or interſtice between them; they had recourſe to this machine to ſupport the doctrine of an abſolute plenum, and to make it conſiſtent with the phænomenon of motion, &c. See CARTESIAN PHILOSOPHY.

MATERIA CHEMICA, a term uſed by authors to expreſs ſuch bodies as are the peculiar objects of chemical experiments.

MATERIA MEDICA comprehends all the ſubſtances either uſed in medicine in their natural ſtate, or which afford preparations that are ſo; theſe belong partly to the animal, partly to the vegetable, and partly to the foſſile kingdom.

MATHEMATICS, that ſcience which conſiders magnitudes either as they are computable or meaſurable; that part which relates to number only, is called arithmetic; and that which relates to meaſure in general, whether length, breadth, depth, motion, force, &c. is called geometry.

The word is Greek, μαθηματικη, ſignifying the ſame thing, which is derived from μαθητης, a diſciple, and that from μανθανω, to teach.

The firſt who cultivated mathematics after the flood were the Aſſyrians and Chaldeans, from whom, ſays Joſephus, they were carried by Abraham to the Egyptians, and among theſe Ariſtotle fixes the firſt riſe of mathematics. From Egypt, 584 years before Chriſt, they paſſed into Greece through the hands of Thales; after him came Pythagoras, who paid a particular regard to arithmetic, fetching the greateſt part of his philoſophy from numbers; he firſt, according to Laertius, abſtracted geometry from matter; and to him we owe the doctrine of incommenſurable magnitude, the five regular bodies, beſides the principles of muſic and aſtronomy. To him ſucceeded Anaxagoras, Oenopides, Briſo, Antipho, and Hippocrates of Scio, who all applied to the quadrature of the circle, duplicature of the cube, &c. but the laſt with moſt ſucceſs, and Proclus mentions him as the firſt compiler of mathematical elements.

Democritus excelled in mathematics as well as phyſics. The next is Plato, who not only improved geometry, but introduced it into phyſics. Out of his ſchool proceeded a croud of mathematicians, among whom was Leodamus, who improved the analyſis firſt invented by Plato; Theætetus, who wrote on elements, and Archytas, who firſt applied mathematics to uſe in life. Theſe were ſucceeded by Neocles and Theon. Eudoxus excelled in arithmetic and geometry, and was the firſt founder of a ſyſtem of aſtronomy. Menechonus improved the elements.

Ariſtotle's works are ſtored with mathematics; out of whoſe ſchool came Eudemus and Theophraſtus; the firſt wrote of numbers, geometry, and inviſible lines; the latter a mathematical hiſtory. To Ariſteus, Iſidorus, and Hypſicles, we owe the books of ſolids, which, with the other books of elements, were improved and methodiſed by Euclid, who died 284 years before Chriſt.

An hundred years after Euclid, came Eratoſthenes and Archimedes; cotemporary with the latter was Conon. Soon after came Apollonius Pergæus, whoſe conics are ſtill extant. Hipparchus and Menelaus wrote on the ſubtenſes in a circle, the latter on ſpherical triangles. Theodoſius's three books of ſpherics are ſtill extant.

In the year 70, Ptolemy of Alexandria was born; he was ſucceeded by Plutarch the philoſopher; after him came Eutocius, who commented on Archimedes, and occaſionally mentions ſeveral inventions on the duplicature of the cube. To Cteſebes of Alexandria we owe our pumps, and Geminus came ſoon after, whom Proclus prefers to Euclid himſelf.

Diophantus of Alexandria was a great maſter of numbers, and firſt inventor of algebra. Nicomachus is celebrated for his arithmetical, geometrical, and muſical works; Serenus, for his books on the ſection of the cylinder; Proclus, for his comments on Euclid: and Theon is, by ſome, thought to be the author of Euclid's Elements. Pappus of Alexandria flouriſhed in the year 400, and his books of Mathematical Collections are ſtill extant.

Dr. Barrow gives a moſt elegant deſcription of the excellence and uſefulneſs of mathematical knowledge, in his Inaugural Oration, upon being appointed profeſſor of mathematics at Cambridge.

The mathematics, he obſerves, effectually exerciſe, not vainly delude, nor vexatiouſly torment ſtudious minds with obſcure ſubtilties; but plainly demonſtrate every thing within their reach, draw certain concluſions, inſtruct by profitable rules, and unfold pleaſant queſtions. Theſe diſciplines likewiſe enure and corroborate the mind to a conſtant diligence in ſtudy; they wholly deliver us from a credulous ſimplicity, moſt ſtrongly fortify us againſt the variety of ſcepticiſm, effectually reſtrain us from a raſh preſumption, moſt eaſily incline us to a due aſſent, perfectly ſubject us to the government of right reaſon. While the mind is abſtracted and elevated from ſenſible matter, diſtinctly views pure forms, conceives the beauty of ideas, and inveſtigates the harmony of proportions; the manners themſelves are ſenſibly corrected and improved, the affections compoſed and rectified, the fancy calmed and ſettled, and the underſtanding raiſed and excited to more divine contemplations.

Mathematics are commonly diſtinguiſhed into pure and ſpeculative, which conſider quantity abſtractedly; and mixed, which treat of magnitude as ſubſiſting in material bodies, and conſequently are interwoven every where with phyſical conſiderations.

Mixed mathematics are very comprehenſive; ſince to them may be referred aſtronomy, optics, geography, hydrography, hydroſtatics, mechanics, fortification, navigation, &c. See the articles ASTRONOMY, OPTICS, &c.

Pure mathematics have one peculiar advantage, that they occaſion no diſputes among wrangling diſputants, as in other branches of knowledge; and the reaſon is, becauſe the definitions of the terms are premiſed, and every body that reads a propoſition has the ſame idea of every part of it. Hence it is eaſy to put an end to all mathematical controverſies, by ſhewing either that our adverſary has not ſtuck to his definitions, or has not laid down true premiſes, or elſe that he has drawn falſe concluſions from true principles; and in caſe we are able to do neither of theſe, we muſt acknowledge the truth of what he has proved.

MATRICARIA, FEVERFEW, in botany. See FEVERFEW.

MATRICULA, a regiſter kept of the admiſſion of officers and perſons entered into any body or ſociety, of which a liſt is made.

MATRIX, *Uterus*, the womb, in anatomy, that part of the female of any kind, where the fœtus is conceived and nouriſhed till the time of its delivery. See UTERUS.

MATRIX alſo denotes a place proper for the generation of vegetables, minerals, and metals.

MATRIX, in letter foundery. See the article FOUNDERY.

MATRONALIA, a feſtival of the ancient Roman matrons, from whom it had its name. It was celebrated on the kalends of March in honour of the god Mars: and was to the Roman ladies what the feſtival of the Saturnalia was to their huſbands; for at this time they ſerved their women ſlaves at table, and received preſents from their huſbands.

MATROSSES are ſoldiers in the train of artillery, who are next to the gunners, and aſſiſt them in loading, firing, and ſpunging the great guns. They carry firelocks, and march along with the ſtore-waggons, both as a guard, and to give their aſſiſtance in caſe a waggon ſhould break down.

MATTER, *Materia*, in phyſiology, whatever is extended and capable of making reſiſtance: hence, becauſe all bodies, whether ſolid or fluid, are extended, and do reſiſt, we conclude that they are material, or made up of matter.

matter. The Carteſians, it is true, make matter to conſiſt in extenſion alone; but extenſion, without reſiſtance, is nothing but mere ſpace. That matter is one and the ſame thing in all bodies, and that all the variety we obſerve ariſes from the various forms and ſhapes it puts on, ſeems very probable, and may be concluded from a general obſervation of the procedure of nature in the general formation and deſtruction of bodies. Thus, for inſtance, water, rarefied by heat, becomes vapour; great collections of vapours form clouds; theſe condenſed deſcend in the form of hail or rain; part of this collected on the earth conſtitutes rivers; another part mixing with the earth enters into the roots of plants, and ſupplies matter to, and expands itſelf into various ſpecies of vegetables. In each vegetable it appears in one ſhape in the root, another in the ſtalk, another in the flowers, another in the ſeeds, &c. From hence various bodies proceed; from the oak, houſes, ſhips, &c. from hemp and flax we have thread; from thence our various kinds of linnen; from thence garments; theſe degenerate into rags, which receive from the mill the various forms of paper; hence our books; which by fire are converted partly into water, partly into oil, another part into air, a fourth part into ſalt, and a fifth into earth; which are called the elements of bodies; and which, mixed with common earth, are again reſuſcitated in various forms of bodies.

Sir Iſaac Newton thinks it highly probable, that God in the beginning formed matter into ſolid, maſſy, impenetrable, moveable particles, or atoms, of ſuch ſizes and figures, and with ſuch other properties, and in ſuch proportion to ſpace, as moſt conduced to the end for which he formed them; and that theſe primitive particles being ſolids, are incomparably harder than any porous bodies compounded of them, even ſo hard as never to wear or break in pieces; no ordinary power being able to divide what God himſelf made one in the firſt creation. While theſe particles continue entire, they may compoſe bodies of one and the ſame nature and texture in all ages; but ſhould they wear away, or break in pieces, the nature of things depending on them may be changed. Water and earth, compoſed of old worn particles and fragments of particles, would not be of the ſame nature and texture now, with water and earth compoſed of entire particles in the beginning; and therefore, that nature may be laſting, the changes of corporeal things are to be placed only in the various ſeparations and new aſſociations of motions of theſe permanent particles, compound bodies being apt to break, not in the midſt of ſolid particles, but where theſe particles are laid together, and only touch in a few points. See the article ATOM.

MATTER *in Deed*, in law, ſignifies a particular matter of fact to be proved by ſome deed, and is frequently mentioned with matter of record; as where a man, during his abſence abroad in the king's ſervice, is ſued to an exigent; in which caſe, if ſuch perſon would take advantage of this matter in deed, he muſt alledge it before a ſcire facias for execution is awarded againſt him, otherwiſe he can have no relief but from matter of record; that is, ſome error in the proceedings appearing upon the face of the record.

MATTHEW, *or Goſpel of St.* MATTHEW, a canonical book of the New Teſtament.

St. Matthew wrote his Goſpel in Judea, at the requeſt of thoſe he had converted, and it is thought he began it in the year 41, eight years after Chriſt's reſurrection. It was written, according to the teſtimony of all the ancients, in the Hebrew or Syriac language, which was then common in Judea; but the Greek verſion of it, which now paſſes for the original, is as old as the apoſtolical times. St Matthew's view in writing his Goſpel, was chiefly to ſhew the royal deſcent of Jeſus Chriſt, and to repreſent his life and converſation among men. No one of the Apoſtles enters ſo far into the particulars of the actions of Jeſus Chriſt, or has given ſo many rules for the conduct of life. If we compare him with the other three evangeliſts, we may obſerve a remarkable difference in the order and ſucceſſion of our Saviour's actions, from chap iv. to chap. xiv. 13. Some have imputed this variation of St. Matthew to mere chance; and others to choice and deſign: however, it can be no prejudice to the truth of the facts, which are the eſſential part of the goſpel; and as to the order of time, the ſacred authors were not always ſolicitous about it.

St. MATTHEW *the Evangeliſt's Day*, a feſtival of the Chriſtian church, obſerved on September the twenty-firſt.

St. MATTHIAS's *Day*, a feſtival of the Chriſtian church, obſerved on the twenty-fourth of February.

MATTINS, the firſt canonical hour, or the firſt part of the daily ſervice in the Romiſh church.

MATURATION, in ſurgery, the ſame with ſuppuration. See SUPPURATION.

MAUNCH, in heraldry, the figure of an ancient coat ſleeve, borne in many gentlemen's eſcutcheons.

MAUNDY-THURSDAY is the Thurſday in Paſſion-week, which was called Maunday or Mandate Thurſday, from the command which our Saviour gave his Apoſtles to commemorate him in the Lord's Supper, which he this day inſtituted; or from the new commandment which he gave them to love one another, after he had waſhed their feet as a token of his love to them.

Our Saviour's humility in waſhing his diſciples feet, is commemorated on this day by moſt Chriſtian kings, who waſh the feet of a certain number of poor people, not indeed with their own royal hands, but by the hands of their lord almoner, or ſome other deputy.

MAUSOLEUM, a magnificent tomb, or funeral monument. The word is derived from Mauſolus, king of Caria, to whom Artemiſia, his widow, erected a moſt ſtately monument, eſteemed one of the wonders of the world, and called it, from his name, Mauſoleum.

MAXILLA, the jaws, or thoſe parts of an animal in which the teeth are ſet.

The jaws are ſhorter in the human frame than in that of any other animal, in proportion to the ſize of the body; and this is a circumſtance that adds greatly to the beauty of the face. The upper jaw is compoſed of thirteen bones, twelve of which are in pairs: theſe are, 1. the lachrymal; 2. the naſal; 3. the jugal; 4. the maxillar; 5. the ſpongioſum inferius; 6. the palatine: the thirteenth is an odd bone, and is called the vomer. Theſe ſeveral bones of the upper maxilla are united to one another by a kind of juncture, which appears equal and even, and is called by anatomiſts *juncture per harmoniam*.

The maxilla inferior, or lower jaw, is that moveable bone of the head which contains the lower ſeries of teeth; this is compoſed of two bones which unite in the middle of the chin, by the intervention of a cartilage, which hardens as the child grows, and at length becoming bony, joins the two bones into a continued one, reſembling the Greek υ. It conſiſts of two tables, between which there is a ſpongy ſubſtance, which in children is medullary. The fore part is ſhallow, and juſt ſufficient to contain the ſockets of ſixteen teeth. It has two proceſſes, the coronoide and condyloides; four foramina or holes for the paſſage of blood-veſſels and nerves, and ſix pair of muſcles, of which two are depreſſors, and four elevators; the depreſſors are called the platyſma myoides, and the biventer; and the four pair of elevators are, the crotaphites, the maſſeters, and the internal and external pterygoidæi, which ſee under their ſeveral names. There is alſo the maxillary gland, ſituated on the inſide under the lower jaw bone. See the article GLAND.

MAXIMUM, in mathematics, the greateſt quantity attainable in any given caſe, and ſo ſtands oppoſed to minimum.

Methodus de MAXIMIS *et Minimis*, in mathematics, a method ſo called, whereby the greateſt or leaſt poſſible quantity attainable in any caſe is arrived at.

Thus (plate LXXXV. *fig.* 4.) if the ordinate BC, flowing according to the direction AF, continually increaſes till it arrives at a certain place DE, after which it begins to diminiſh, the ordinate DE, in this caſe, is called the greateſt ordinate, or a maximum.

On the contrary, if (*fig.* 5.) the ordinate BC, flowing according to the direction AF, continually decreaſes, till it come into the place DE, and after that it begins to increaſe, the ordinate DE, in this caſe, is called the leaſt ordinate, or a minimum.

And how to determine the greateſt or leaſt ſtate; that is, how to find the value of the correſpondent abſciſſe AD,

from the equation expreſſing the nature of the curve, is the proper buſineſs of the method de maximis and minimis.

And, to this end, we muſt obſerve that the fluxion of the ordinate BC is to the fluxion of the abſciſſe AB, as the ordinate BC is to the ſubtangent VB. Let us now ſuppoſe the ordinate BC (*fig.* 4.) in a flowing ſtate moving according to the direction AF, it is manifeſt that, the nearer the ordinate BC approaches the ordinate DE, the greater will be the ſubtangent BV, till when the ordinate BC arrives at, or is coincident with the ordinate DE, the tangent HEI to the point E, will be parallel to the axis AF; conſequently the ſubtangent BV will become infinite, in reſpect to the ordinate DE, and the fluxion of the ordinate itſelf will vaniſh, or become equal to nothing.

Whence to find the value of the correſpondent abſciſſe, in this caſe let the fluxionary value of the ordinate, deduced from the equation expreſſing the nature of the curve, be put equal to 0, or nothing; by which means all thoſe members of the equation in which it is found will vaniſh, and thoſe that remain will determine the place of the maximum.

For example in (*fig.* 4.) let $AB = x$, $BC = y$, $AF = 2a$. Let us ſuppoſe the equation of the curve to be $2ax - xx = yy$, and let it be required to find the greateſt ordinate, or, which is the ſame thing, the length of its correſpondent abſciſſe AB. Now becauſe $2a\dot{x} - 2x\dot{x} = 2y\dot{y}$, whence $a\dot{x} - x\dot{x} = y\dot{y}$, we ſhall have $\dot{y} = \frac{a\dot{x} - x\dot{x}}{y}$, which being put equal to nothing, we ſhall have $\frac{a\dot{x} - x\dot{x}}{y} = 0$; whence $a\dot{x} - x\dot{x} = 0$, and $a - x = 0$; conſequently $a = x$; that is, AD will be equal to half AF.

Again, let us now ſuppoſe the ordinate BC (*fig.* 6.) to move according to the direction AD; it is likewiſe manifeſt that, the nearer the point B approaches to the point D, the leſſer will be the ſubtangent BV; till at laſt when the point B arrives at, or is coincident with the point D, the ſubtangent BV will vaniſh, and the fluxion of the ordinate will become infinite.

Whence to find the value of the abſciſſe in this caſe, let the fluxionary value of the ordinate be made equal to infinite, then will the infinitely ſmall terms vaniſh, and the remainder will determine the minimum.

For example, let us ſuppoſe $y - a = x^{\frac{1}{3}} \times \overline{a - x^{\frac{2}{3}}}$ to be the equation of the curve (having firſt ſuppoſed $AB = x$, and $BC = y$) then will $\dot{y} = -\frac{2\dot{x} \times \overline{a,^{\frac{1}{3}}}}{3\overline{a - x^{\frac{1}{3}}}}$ which being put equal to an infinite quantity, we ſhall have $3\overline{a - x^{\frac{1}{3}}} = 0$ (for the numerator $-2\dot{x} \times \overline{a^{\frac{1}{3}}}$ in this caſe vaniſhes) whence $a - x = 0$, and $a = x$, that is, $AB = x$ becomes equal to AD, whence AD is the correſpondent abſciſſe.

And hence we are taught a direct method to determine the maximum or minimum in any caſe whatſoever.

MAY, *Maius*, the fifth month of the year, conſiſting of thirty-one days. See the articles MONTH and YEAR.

MAYOR, the chief magiſtrate of a city or town, choſen annually out of the aldermen.

MEAD, a liquor made of honey, and held in great eſtimation by moſt of the northern nations, but perhaps not eſteemed here ſo much as it might deſerve if due care was taken to prepare it properly.

All the writers who have hitherto treated of this ſubject, have given into a capital error with regard to the ſtrength of this liquor, by directing too great a proportion of honey to be diſſolved in the water. The uſual practice of making it ſo ſtrong as to bear an egg, is very wrong. The liquor is thereby rendered a mere ſtum, and this bad quality is ſtill increaſed by the long boiling generally practiſed. It is ſcarcely poſſible to procure honey ſo pure, but that ſome bee-bread, wax, or other ſubſtance is mixed with it, and this cannot be perfectly ſeparated from it, but by boiling. On this account the boiling of mead ſeems indiſputably neceſſary. In order the more effectually to ſeparate theſe impurities from the liquor, it will be adviſeable to mix ſome whites of eggs with it before it is put on the fire, and it will be particularly neceſſary to ſkim off the thick ſcum that riſes, the moment the liquor begins to boil; and this muſt be attentively continued ſo long as it boils. The only method of boiling being here to ſeparate the impurities, and to make a perfect union of the water and the honey, both which purpoſes are very ſoon obtained, it evidently appears that the boiling need be of but very ſhort duration. This becomes here more peculiarly neceſſary, becauſe the liquor will be the leſs diſpoſed to ferment kindly, the longer the boiling has been continued. It is perhaps owing to the ſingle article of long boiling, that mead has hitherto lain under ſo great diſcredit; becauſe it then never fermented ſufficiently to take off its luſcious ſweetneſs; whereas had it undergone a due fermentation, that ſweetneſs would have gone off, and the mead would have attained a fine racy flavour.

Some notable houſewifes have added hops to their mead. This helps to take off its ſweetneſs, and, as the bitterneſs of the hop goes off, gives it a pleaſant flavour. A ferment is here, as in all liquors that are boiled, generally wanted to bring on a perfect fermentation: but as the leaſt taint in the ferment is communicated to the whole liquor, particular care ſhould be taken that it be very ſweet and good. Mead, judiciouſly manag'd on theſe principles, will keep for years, and be improved by age.

MEADOW, in its general ſignification, means paſture, or graſs-land, annually mown for hay; but is more particularly applied to lands that are ſo low as to be too moiſt for cattle to graze upon them in winter, without ſpoiling the ſward. Too much or too little water is almoſt equally prejudicial to meadows, but the beſt land for meadows is a rich ſoil, that has a moiſt bottom, eſpecially where a ſmall brook may be brought over it, and where there is ſuch a deſcent, that the water will not lodge: theſe are better than thoſe by great rivers, where the crops are often loſt. Thoſe that may be overflowed at pleaſure, are called water meadows; theſe ſhould never be overflowed till the end of March, except once or twice in winter, when there are ſuch floods as bring down a great deal of ſoil from the upper-lands, and if the ſeaſon ſhould prove dry, it will be of great ſervice to the graſs, if the meadows are overflowed again; but then the cattle ſhould not be turned in till the ſward is dry enough to bear their weight. Miller recommends the weeding of meadows in April and October, with a ſpaddle, and rolling them with a heavy rollet in ſpring and autumn. See PASTURE.

MEAN, in general, denotes the middle between two extremes: thus we ſay, mean diſtance, mean proportion &c. See the articles DISTANCE, PROPORTION, &c.

MEASLES, in medicine, a cutaneous diſeaſe, attended with a fever, in which there is an appearance of eruptions that do not tend to a ſuppuration. The meaſles begin with chillneſs and ſhivering, and heat and cold ſucceed by turns. The next day the fever comes on, with great ſickneſs, thirſt, and loſs of appetite; the tongue is white, but not dry; there is a little cough, a heavineſs of the head and eyes, and a continual ſleepineſs; then follows a ſneezing, and ſwelling of the eye-lids, and a ſerous humour often diſtils from the noſe and eyes, which are certain ſigns that the eruption is at hand. In the face, the ſpots are ſmall, but on the breaſt broad and red. The patient vomits, but oftener has a looſeneſs with greeniſh ſtools. Theſe ſymptoms continue and increaſe till the fourth, and ſometimes the fifth day, at which time the ſpots, which are like flea bites, increaſe in number and magnitude, but riſe little above the ſkin. The ſymptoms do not immediately vaniſh after the eruption, as in the ſmall-pox, except the vomiting. The cough and fever increaſe, with difficulty of breathing. About the ſixth day, the ſkin of the face and forehead begins to grow rough, and the cuticle breaking, the puſtules die away; and on the eighth day the ſpots diſappear in the face, and are ſcarce viſible any where elſe; on the ninth they quite vaniſh, and fine, thin, light ſcales, fall from the ſkin.

The meaſles are in general not dangerous, unleſs from an inſalubrious epidemical conſtitution of the year, which ſometimes renders them malignant: which may be known

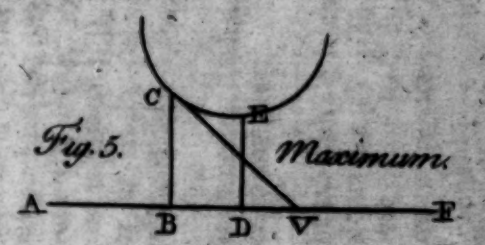

Fig. 6. Maximum.

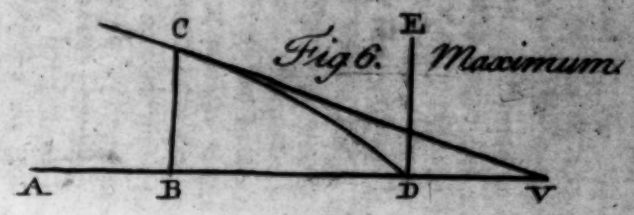

5 JA 59

by a ſudden loſs of ſtrength, coldneſs of the extreme parts, great reſtleſſneſs, and a delirium. Thoſe who die of the meaſles are generally ſuffocated on the ninth day. Some have a looſeneſs, which continues ſeveral weeks, and brings on a mortal tabes. Some have a ſlow fever, with an atrophy and a ſwelling of the abdomen, which are fatal; and when a cough and hoarſeneſs remain after the diſeaſe, a conſumption will follow without ſpeedy aſſiſtance.

If children are ſuſpected to abound with crudities in the inteſtines, it will be proper to evacuate with half a grain of tartar emetic, and ſyrup of ſuccory with rhubarb. When there are worms, anthelmintics ſhould be given. In adults abounding with blood, phlebotomy is neceſſary on the firſt days; and as ſoon as the eruption is ended a gentle cathartic is proper: in a cough, nothing is better than oil of almonds freſh drawn, mixt with ſyrup of capillaire; half a ſpoonful of which ſhould be often given in water-gruel. The patient ſhould keep his bed for two days after the firſt eruption, and take abſorbent and diaphoretic powders, to which half a grain of ſaffron may be added; theſe ſhould be taken every night from the firſt onſet of the diſeaſe, till the patient recovers, encreaſing or diminiſhing the doſe according to his age. If after the meaſles diſappear, they ſhould be followed by a difficulty of breathing, a fever, and other ſymptoms of an inflammation of the lungs, let blood be taken freely from the arm, once, twice, or three times, as occaſion ſhall require, leaving a due ſpace between each bleeding, and give oil of ſweet almonds, and about twelve days from the invaſion let the patient be purged. The diet ought to be the ſame as in the ſmall-pox, taking particular care that the body be kept lax rather than bound up, through the courſe of the diſtemper. See Pox.

MEASURE, *Menſura*, in geometry, denotes any quantity aſſumed as one, or unity, to which the ratio of other homogeneous or ſimilar quantities is expreſſed. This definition is ſomewhat more agreeable to practice than that of Euclid, who defines meaſure, a quantity which being repeated any number of times, becomes equal to another. This latter definition anſwers only to the idea of an arithmetical meaſure, or quota-part.

MEASURE *of an Angle* is an arch deſcribed from the vertex in any place between its legs.

Hence angles are diſtinguiſhed by the ratio of the arches, deſcribed from the vertex between the legs to the peripheries. Angles then are diſtinguiſhed by thoſe arches; and the arches are diſtinguiſhed by their ratio to the periphery: thus an angle is ſaid to be ſo many degrees as there are in the ſaid arch. See the article ANGLE.

MEASURE *of a Figure*, or plane ſurface, is a ſquare whoſe ſide is one inch, foot, yard, or ſome other determinate length. Among geometricians, it is uſually a rod called a ſquare rod, divided into ten ſquare feet, and the ſquare feet into ten ſquare digits.

MEASURE *of a Line*, any right line taken at pleaſure, and conſidered as unity. The modern geometricians uſe a decempeda, or perch divided into ten equal parts, called feet; the feet they ſubdivide into ten digits, and the digit into ten lines, &c.

MEASURE *of the Maſs, or Quantity of Matter*, in mechanics, is its weight; it being apparent that all the matter which coheres and moves with a body, gravitates with it, and it being found by experiment, that the gravities of homogeneal bodies are in proportion to their bulks; hence, while the maſs continues the ſame, the weight will be the ſame, whatever figure it put on: by which is meant its abſolute weight, for as to its ſpecific, that varies as the quantity of the ſurface varies. See the article GRAVITY and MOMENT.

MEASURE *of a Number*, in arithmetic, ſuch a number as divides another without leaving any fraction: thus 9 is a meaſure of 27.

MEASURE *of a Solid*, is a cube whoſe ſide is one inch, foot, yard, or any other determinate length. In geometry, it is a cubic perch, divided into cubic feet, digits, &c. hence cubic meaſures, or meaſures of capacity. See the articles SPHERE, CUBE, &c.

MEASURE *of Velocity*, in mechanics, the ſpace paſſed over by a moving body in a given time. To meaſure a velocity therefore, the ſpace muſt be divided into as many equal parts as the time is conceived to be divided into; the quantity of ſpace anſwering to ſuch an article of time is the meaſure of the velocity. See the article VELOCITY.

MEASURE, in a legal and commercial ſenſe, denotes a certain quantity or proportion of any thing bought, ſold, valued, or the like. Meaſures are then various, according to the various kinds and dimenſions of the things meaſured. Hence ariſe lineal or longitudinal meaſures, for lines or lengths; ſquare meaſures, for areas or ſuperficies; and ſolid or cubic meaſures, for bodies and their capacities. All which again are very different in different countries, and in different ages, and even many of them for different commodities. Whence ariſe other diviſions of ancient and modern meaſures, domeſtic and foreign ones, dry meaſures, liquid meaſures, &c.

Long MEASURES, or MEASURES *of Application*. The Engliſh ſtandard long meaſure for commerce, or that whereby the quantities of things are ordinarily eſtimated in the way of trade, is the yard, containing three Engliſh feet. Its diviſions are the foot, ſpan, palm, inch, and barley-corn; its multiples the pace, fathom, pole, furlong, and mile. The proportions theſe ſeverally bear to each other, are expreſſed in the following table.

English MEASURES of Length.

	Barley-corns	Inch	Palm	Span	Foot	Cubit	Yard	Pace	Fathom	Pole	Furlong	Mile.

100	of Milan — — — — — —	58½

N. B. The aunes or ells of Amſterdam, Haerlem, Leyden, the Hague, Rotterdam, and other cities of Holland, as alſo that of Nuremberg, being all equal, are comprehended under that of Amſterdam; as thoſe of Oſnabrug are under thoſe of France; and thoſe of Bern and Baſil are equal to thoſe of Hamburg, Francfort, and Leipſic.

For the ſubdiviſions and multiples of each of theſe meaſures of length, ſee the article AUNE, &c.

For the proportion of the feet of the principal nations in Europe, compared with the Engliſh foot, ſee the article FOOT.

Square, or *Superficial* MEASURES. Engliſh ſquare or ſuperficial meaſures are raiſed from the yard of 36 inches multiplied into itſelf, and thus producing 1296 ſquare inches in the ſquare yard: the diviſions of this are ſquare feet and inches; and the multiples, poles, roods, and acres, as in the following table.

English Square-MEASURES.

Inches	Feet	Yards	Paces	Poles	Rood	Acre.
144						
1296	9					
3600	25	2⅞				
39204	272¼	30¼	10.89			
1568160	10890	1210	435.6	40		
6272640	43560	4840	1743.6	160	4	

Grecian ſquare-meaſures were the plethron, or acre, by ſome ſaid to contain 1444, by others 10000 ſquare feet; and the aroura, the half of the plethron. The aroura of the Egyptians was the ſquare of 100 cubits.

Cubical MEASURES, or *Meaſures of Capacity for Liquids.* — The Engliſh meaſures were originally raiſed from troy-weight; it being enacted by ſeveral ſtatutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, ſhould weigh a gallon of wine-meaſure, the diviſions and multiples whereof were to form the other meaſures; at the ſame time it was alſo ordered, that there ſhould be but one liquid meaſure in the kingdom: yet cuſtom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a ſecond ſtandard-gallon adjuſted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter ſtandard are raiſed two ſeveral meaſures, the one for ale, the other for beer.

The ſealed gallon at Guildhall, which is the ſtandard for wines, ſpirits, oils, &c. is ſuppoſed to contain 231 cubic inches; and on this ſuppoſition the other meaſures raiſed therefrom, will contain as in the following table: yet by actual experiment, made in 1688, before the lord-mayor and the commiſſioners of exciſe, this gallon was found to contain only 224 cubic inches: it was however agreed to continue the common ſuppoſed contents of 231 cubic inches; ſo that all computations ſtand on their old footing. Hence as 12 is to 231, ſo is 14$\frac{43}{56}$ to 281 ½ the cubic inches in the ale-gallon: but in effect the ale-quart contains 70 ½ cubic inches, on which principle the ale and beer-gallon will be 282 cubic inches. The ſeveral diviſions and multiples of theſe meaſures, and their proportions, are exhibited in the following tables.

In the modern liquid-meaſures of foreign nations, it is to be obſerved, that their ſeveral veſſels for wine, vinegar, &c. have alſo various denominations, according to their different ſizes, and the places wherein they are uſed. The Woeders of Germany, for holding Rhenish and Moſelle wines, are different in their gauges; ſome containing 14 aumes of Amſterdam meaſure, and others more or leſs. The aume is reckoned at Amſterdam to 8 ſteckans or 20 verges, or for ⅛ of a ton of 2 pipes; or 4 barrels of France or Bourdeaux, which ⅛ at this last place is called tiercon, becauſe 3 of them make a pipe or 2 barrels, and 6 the ſaid ton. The ſteckan is 16 mingles, or 3 pints; and the verge is, in reſpect of the ſaid Rhenish and Moſelle and ſome other ſorts of wine, of 6 mingles; but in meaſuring brandy, it conſiſts of 6 ⅛ mingles. The aume is divided into 4 anckers, and the ancker into 2 ſteckans or 32 mingles. The ancker is taken ſometimes for ⅛ of a ton, or 4 barrels, on which footing the Bourdeaux barrel ought to contain at Amſterdam (when the caſk is made according to the juſt gauge) 12 ½ ſteckans, or 200 mingles, wine and lees; or 12 ſteckans, or 192 mingles racked wine; ſo that the Bourdeaux ton of wine contains 50 ſteckans, or 800 mingles, wine and lees; and 48 ſteckans, or 768 mingles of pure wine. The barrels or poinçons of Nantes and other places on the river Loire contain only 12 ſteckans Amſterdam meaſure. The wine-ton of Rochelle, Cognac, Charente, and the Iſle of Rhé, differs very little from the ton of Bourdeaux, and conſequently from the barrels and pipes. A ton of wine of Chaloſſe, Bayonne, and the neighbouring places, is reckoned 60 ſteckans, and the barrel 15, Amſterdam meaſure.

The muid of Paris contains 150 quarts, or 300 pints, wine and lee; or 280 pints clear wine; of which muids 3 make a ton, and the fractions are,

The muid	containing	36 ſetiers
The ſetier		4 quarts
The quart		2 pints
The pint		2 chopins
The chopin		2 demi-ſetiers
The demi-ſetier		2 poiſſons.

The muid is alſo compoſed of pipes, or poinçons, quarteaux, queves, and demiqueves: theſe poinçons of Paris and Orleans contain about 15 ſteckans Amſterdam-meaſure, and ought to weigh with the caſk 666 lb. a little more or leſs. In Provence they reckon by milleroles, and the millerole of Toulon contains 66 Paris-pints, or 100 pints of Amſterdam, nearly; and the Paris-pint is nearly equal to the Engliſh wine-quart.

The butts or pipes from Cadiz, Malaga, Alicant, Benecarlo, Saloe, and Mataro, and from the Canaries, from Liſbon, Oporto, and Fayal, are very different in their gauges, tho' in affreightments they are all reckoned two to the ton.

Vinegar is meaſured in the ſame manner as wine; but the meaſures for brandies are different: theſe ſpirits from France, Spain, Portugal, &c. are generally ſhipped in large caſks called pipes, butts, and pieces, according to the places from whence they are exported, &c. In France, brandy is ſhipped in caſks called pieces at Bourdeaux, and pipes at Rochelle, Cognac, the Iſle of Rhé, and other neighbouring places, which contain ſome more and ſome leſs: even from 60 to 90 Amſterdam-verges or veertels, according to the capacity of the veſſels, and the places they come from, which being reduced into barrels, will ſtand as follows, viz.

At Rochelle, Cognac, the Iſle of Rhé, and the country of Aunis —	27 veertels	per barrel.
At Nants, and ſeveral places of Bretagne and Anjou — —	29 veertels	
At Bourdeaux, and different parts of Guienne — —	32 verges	
At Amſterdam, and other cities of Holland — —	30 veertels	
At Hamburgh and Lubeck —	30 verges	
At Embden — —	27 verges	

In Provence and Languedoc, brandy is ſold by the quintal, the caſks included; and at Bruges, in Flanders, the verges are called ſeſters of 16 ſtops each, and the ſpirit is ſold at ſo much per ſtop.

Olive-oil is alſo ſhipped in caſks of various ſizes, according to the cuſtom of the places where it is embarked, and the conveniency of ſtowage. In England it is ſold by the ton of 236 gallons; and at Amſterdam by the ton of 717 mingles, or 1434 pints. In Provence it is ſold by milleroles of 66 Paris-pints: from Spain and Portugal it is brought in pipes, or butts, of different gauges; at the firſt place it is ſold by roves, whereof 40 go to the butt; and at the latter place by almoudas, whereof 26 make a pipe. Train-oil is ſold in England by the ton, at Amſterdam by the barrel.

MEASURES *of Capacity for Things dry.* Engliſh dry or corn-meaſures are raiſed from the Wincheſter-gallon, which contains 272¼ ſolid inches, and ought to hold of pure running water 9 pounds 13 ounces. This ſeems to ſtand on the foot of the old wine-gallon of 224 cubic inches, 12 being to 14 $\frac{12}{16}$ as 224 to 272 ¼; but by an act of parliament made in 1697 it is decreed, that a round buſhel, 18 ½ inches wide, and 8 deep, is a legal Wincheſter-buſhel. Now ſuch a buſhel will only hold 2150.42 cubic inches, conſequently the gallon will hold 268.8 cubic inches, the diviſions and multiples whereof are in the following table:

English Dry or Corn MEASURE.

In the ſeveral parts of Europe, ſalt, which is a more ſtaple and current commodity than any other, is bought and ſold by different meaſures, according to the ſeveral places of its diſpatch: at Amſterdam it is ſold by the cent of 404 meaſures, or ſcheppels, which cent is reckoned to be ſeven laſts, or 14 tons, and the laſt is to weigh 4000 lb. the ſeven laſts making 28000 lb. called the cent of ſalt, which alſo contains 208 ſacks; though ſome of this commodity is much heavier than others. In the cities of France, ſalt is ſold by the muid, whoſe ſize varies according to the different places of its manufacture and diſpatch. At Paris this meaſure is reckoned to contain 12 ſetiers, or 48 minots, which minot is alſo divided into other meaſures. The cent of ſalt from Marans, Brouage, Sude, and the Iſle of Rhé, contain 28 ſtricken muids, and each muid 24 boiſeaux, which yields at Amſterdam 11 ½ laſts, or 23 tons, more or leſs. In Copenhagen, the ſaid cent renders only 9 ½ laſts, the laſt being reckoned here equal to 18 tons, and 50 laſts to correſpond with 52 of Coningſberg, at which place the cent produces about 10 laſts, or 40,000 lb. At Riga the ſaid cent yields the ſame meaſure as at Coningſberg, and about 6 ¼ laſts of Riga, make the great cent of Amſterdam. The ſaid French cent produces at Dantzick from 11 ½ to 12 laſts, of which laſts from 7 ¼ to 7 ½, make likewiſe the great cent of Amſterdam. At Stetin in Pomerania, the French cent yielded 10 laſts, making 40,000 meaſure and weight of the ſaid place. In Portugal it is bought by the muid, of which four make a laſt, and ſeven the cent of Amſterdam. At Alamat and Ivica it is ſold by the modin, which weighs from 27 ½ to 28 hundred weight Engliſh.

MEASURE *of Wood*, for firing. See the article CORD *of Wood.*

MEASURE *for Horſes*, is the hand, which by ſtatute contains four inches.

MEASURE is alſo uſed to ſignify the cadence and time obſerved in poetry, dancing, and muſic, to render them regular and agreeable. See METRE.

MEASURE, in muſic, the interval or ſpace of time which the perſon who beats time takes between the riſing and falling of his hand, in order to conduct the movement ſometimes quicker and ſometimes ſlower, according to the muſic or ſubject that is to be ſung or played. See TIME.

MEATUS AUDITORIUS, in anatomy, the auditory paſſage. See the article EAR.

MECHANICS, that branch of mathematics which conſiders motion and moving powers, their nature and laws, with their effects in machines. See the article MACHINE.

The knowledge of mechanics is one of thoſe things, ſays Mr. Mac Laurin, that ſerves to diſtinguiſh civilized nations from barbarians. It is by this ſcience, that the utmoſt improvement is made of every power and force in nature; and the motions of the elements, water, air, and fire, are made ſubſervient to the various purpoſes of life: for however weak the force of man appears to be, when unaſſiſted by this art; yet, with its aid, there is hardly any thing above his reach. It is diſtinguiſhed, by Sir Iſaac Newton, into practical and rational mechanics; the former of which treats of the mechanical powers, viz. the lever, ballance, axis and wheel, pulley, wedge, ſcrew, and inclined plane. See the articles LEVER, BALLANCE, &c.

Rational mechanics comprehends the whole theory of motion; ſhews, when the powers or forces are given, how

how to determine the motions that are produced by them; and, converſely, when the phænomena of the motions are given, how to trace the powers or forces from which they ariſe. See MOTION.

MECHANICAL, an epithet applied to whatever relates to mechanics: thus we ſay, mechanical powers, cauſes, &c. See the articles POWER, CAUSE, &c.

The mechanical philoſophy is the ſame with what is otherwiſe called corpuſcular philoſophy. See the article CORPUSCULAR.

MECHANICAL, in mathematics, denotes a conſtruction of ſome problem, by the aſſiſtance of inſtruments, as the duplicature of the cube and quadrature of the circle, in contradiſtinction to that which is done in an accurate and geometrical manner.

MECHANICAL *Curve*, is a curve, according to Deſcartes, which cannot be defined by any algebraic equation: and ſo ſtands contradiſtinguiſhed from algebraic or geometrical curve.

Leibnitz and others call theſe mechanical curves tranſcendental, and diſſent from Deſcartes in excluding them out of geometry. Leibnitz found a new kind of tranſcendental equations, whereby theſe curves are defined: but they do not continue conſtantly the ſame in all points of the curve, as algebraic ones do.

MECHOACAN, in the materia medica, the root of an American convolvulus, brought chiefly from a province in Mexico of the ſame name, in thin tranſverſe ſlices, like jalap, but larger and whiter.

This root was firſt introduced about the year 1524, and continued in eſteem for a conſiderable time, as a mild cathartic, of very little taſte or ſmell, not liable to offend the ſtomach, of ſlow operation, but effectual and ſafe: by degrees it gave place to jalap, which has now, among us, almoſt wholly ſuperſeded its uſe. It ſeems to differ from jalap only in being weaker: the reſins obtained from the two roots have the ſame qualities, but mechoacan ſcarcely yields one ſixth part ſo much as jalap does, and hence requires to be given in much larger doſes to produce the ſame effects. The doſe of the mechoacan in ſubſtance is from one dram to two or more.

MECONIUM, in medicine, a black thick fœces gathered in the inteſtines of infants, and brought with them into the world at the time of their birth. The retention of theſe fœces is one of the diſeaſes to which infants are liable; for the cure of which, ſee the article INFANTS.

MECONIUM, in pharmacy, the extract of Engliſh poppies.

MEDAL, a piece of metal in the form of coin, intending to convey to poſterity the portrait of ſome great perſon, or the memory of ſome illuſtrious action.

The parts of a medal are the two ſides, one of which is called the face, or head, and the other the reverſe. On each ſide is the area, or field, which makes the middle of the metal; the rim, or border; and the exergue; and on the two ſides are diſtinguiſhed the type, or the figure repreſented, and the legend, or inſcription.

There was formerly no difference between money and medals. An old Roman had his purſe full of the ſame pieces that we now preſerve in cabinets. As ſoon as an emperor had done any thing remarkable, as gaining a victory, giving up a tax, or the like, it was immediately ſtamped on a coin, and became current through his whole dominions. This was a pretty device to ſpread abroad the virtues of an emperor, and make his actions circulate; and thus a freſh coin was a kind of gazette, that publiſhed the lateſt news of the emperor.

The uſe of medals is very conſiderable: they give a very great light into hiſtory, in confirming ſuch paſſages as are true in old authors, in reconciling ſuch as are told in different manners, and in recording ſuch as have been omitted. In this caſe, a cabinet of medals is a body of hiſtory. It was, indeed, the beſt way in the world to perpetuate the memory of great actions, thus to coin out the life of an emperor, and to put every exploit into the mint. It was a kind of printing before the art was invented; and they have this advantage over books, that they tell their ſtory quicker, and ſum up a whole volume in twenty or thirty reverſes: thus Mr. Vaillant, out of a ſmall collection of medals, has given us a chronicle of the kings of Syria. They are, indeed, the beſt epitomes in the world, and let us ſee, with one caſt of the eye, the ſubſtance of above an hundred pages. Another uſe of medals is, that they not only ſhew the actions of an emperor, but at the ſame time mark out the year in which they were performed; for as every exploit has its date ſet to it, a ſeries of an emperor's coins is his whole life digeſted into annals. A medalliſt, upon the firſt naming of an emperor, will immediately tell his age, family, and life. To remember where he enters in the ſucceſſion, he only conſiders in what part of the cabinet he lies; and by running over in his thoughts ſuch a particular drawer, will give an account of all the remarkable parts of his reign. Nor are medals of leſs uſe in architecture, painting, poetry, &c. A cabinet of medals is a collection of pictures in miniature, and by them the plans of many of the moſt conſiderable buildings of antiquity are preſerved.

MEDALLION, or MEDALION, a medal of an extraordinary ſize, ſuppoſed to be anciently ſtruck by the emperors for their friends, and for foreign princes and embaſſadors; but that the ſmallneſs of their number might not endanger the loſs of the devices they bore, the Romans generally took care to ſtamp the ſubject of them upon their ordinary coins.

Medallions, in reſpect of the other coins, were the ſame as modern medals in reſpect of modern money: they were exempted from all commerce, and had no other value but what was ſet upon them by the fancy of the owner. Medallions are ſo ſcarce that there cannot be any ſet made of them, even though the metals and ſizes ſhould be joined promiſcuouſly.

MEDEOLA, in botany, a genus of the hexandria-trigynia claſs of plants, the flower of which conſiſts of ſix oblong, patent, and revolute petals: the fruit is a berry of a roundiſh form, with three cells, in each of which is contained a ſingle cordated ſeed.

MEDIAL, or ALLIGATION MEDIAL, in arithmetic. See ALLIGATION.

MEDIANA, a vein formed by the concourſe of the cephalic and baſilic veins in the bend of the elbow.

MEDIASTINUM, in anatomy, is a double membrane continuous to the ſternum, ſituated under it, and adhering firmly to it. It divides the cavity of the thorax longitudinally into two parts: but as it is not exactly under the middle of the ſternum, but ſomewhat to the left-ſide, the right-part of the thorax is larger than the left.

The mediaſtinum is connected with the ſternum, pleura, pericardium, and other adjoining parts. It receives veins and arteries from the mammary and diaphragmatic veſſels, and ſometimes has proper and particular ones of its own from the aorta and cava: theſe are then called the mediaſtinal veſſels. Its nerves, which are ſmall, are from the diaphragmatics and the par vagum. It has alſo a number of lymphatics, which run to the ductus thoracicus.

The uſes of the mediaſtinum are two. The firſt is to divide the breaſt longitudinally into two parts, by which ſeveral great purpoſes are anſwered; as, 1. That on one of the lobes of the lungs being ulcerated, the other might not be immediately affected. 2. That water, matter, or any thing elſe contained in one part of the thorax, might not at the ſame time affect both parts of the lungs. 3. That in caſe of a wound in one ſide of the thorax, reſpiration might be continued in the other, and the perſon not be immediately ſuffocated. The ſecond general uſe of the mediaſtinum, is to ſupport the heart in its pendulous ſtate, for the benefit of its free motion, eſpecially when we lie on our backs.

MEDIASTINUM CEREBRI, the ſame with the tranſverſe ſeptum of the brain. See BRAIN.

MEDIATE, or INTERMEDIATE, ſomething that ſtands between and connects two or more terms, conſidered as extremes; in which ſenſe it is oppoſed to immediate.

MEDICAGO, in botany, a genus of the diadelphia-decandria claſs of plants, with a papilionaceous flower, and a long compreſſed and crooked pod for its fruit.

This genus comprehends the medicago, medica falcata, and cochleata of authors.

MEDICINE,

MEDICINE, *Medicina*, or *Phyſic*, the art of healing, which, according to Boerhaave, conſiſts in the knowledge of thoſe things, by whoſe application life is either preſerved ſound and healthy, or, when diſordered, again reſtored to its priſtine healthineſs.

Medicine is undoubtedly of the ſame date with diſeaſes, and diſeaſes are almoſt as ancient as the world itſelf. Men were long each his own phyſician: and it is hard to fix the time when it firſt was made an art and profeſſion. In certain countries thoſe who had been cured of ſome diſeaſe, wrote down how and by what remedies it had been affected, and depoſited thoſe accounts in the temples for the inſtruction of others in the like caſe. In other places, as Egypt and Babylon, the ſick were expoſed in public, that ſuch as paſſed by who might have been cured of the ſame diſeaſe, might give them advice.

The Egyptians cultivated medicine both more anciently and more learnedly than any other people. The Greeks diſputed that glory with them, or at leaſt followed them very cloſe in it.

Before the Trojan war, Chiron the Theſſalian, ſurnamed the Centaur, who was Achilles's governor, made himſelf famous by the cure of wounds, and knowledge of ſimples. Æſculapius, Chiron's diſciple, did not give place to his maſter. Celſus places Pythagoras, Empedocles, and Democritus, in the number of celebrated phyſicians.

Phyſicians were diſtinguiſhed into different claſſes, namely, empirics, becauſe they followed experience almoſt entirely; others, of whom Hippocrates was the chief, joined reaſon with experience, hence called dogmatic or rational. Hippocrates firſt applied himſelf to the ſtudy of natural things in general, and afterwards to that of the human body in particular. He made a great proficiency in all the parts of phyſic. He was born 460 years before Chriſt, and was cotemporary with Democritus. He compiled a body of Greek medicine, which continued a long time ſacred and unaltered, and was the ſtanding practice of many ages. At length Aretæus the Cappadocian digeſted it into an orderly body; after which it was ſeveral times altered and improved, till at length it was taken in hand by Galen of Pergamus, who lived in the year 131. He aſcribed all he knew to Hippocrates, and explained every thing by the rigid doctrines of the Peripatetics; and did both a great deal of ſervice, and a great deal of miſchief to the art; he being the firſt who introduced the doctrine of the elements, the cardinal qualities, the degrees, the four humours, &c. into medicine, and on which he made the whole art depend.

Other famous phyſicians after Hippocrates, were Diocles Caryſtius, Praxagoras, Chryſippus, Eraſiſtrates, Herophilus, Serapion, Apollonius, Glaucias, Heraclides, Tarentinus, Dionyſius, Crito, Menodotus, Theodas, Aſclepiades, Themiſon, Theſſalus, Soranus, Cælius Aurelianus, Celſus, Oribaſius, Aetius, Alexander Trallianus, Paulus Ægineta, Actuarius, Myrepſus, &c.

Phyſic had for ſome time got almoſt entirely into the hands of the Arabians, till the end of the fifteenth century, when the original authors, moſt of which they had tranſlated, came to be read in their own language; at length the immortal Harvey, overturning the whole theory of the ancients, by the diſcovery of the circulation of the blood, laid a new and certain baſis for medicine. Since his time it is improved by ſure diſcoveries in anatomy, chemiſtry, mechanics, &c.

It does not appear that phyſicians were very common among the Hebrews, eſpecially for internal maladies; but for wounds, fractures, bruiſes, and all external injuries, they had phyſicians who underſtood the dreſſing them, and the application of certain medicaments, as roſin, balm, fat, &c. The Jewiſh authors ſpeak very unfavourably of phyſicians.

We are told by Pliny, that Archagathus of Peloponneſus was the firſt phyſician who came to Rome in the conſulſhip of L. Æmilius and L. Julius, A. U. C. 535. That is, the Romans till his arrival, uſed only the ſimple empiric kind of phyſic, ſuch as was practiſed by the firſt men. It ſeems, however, that ſeveral phyſicians came from Greece to Rome, though Cato had oppoſed it with his whole power.

Till Pliny's time, of all profeſſions, that of medicine, as gainful as it was, was the only one no Roman had followed, becauſe they thought it below them.

Without entirely deciding, as to the merit of the ancient and modern phyſic, they have each their peculiar advantages, which render both highly eſtimable; and no doubt but the experience of many ages muſt have added conſiderable lights to the knowledge of the ancients. The new diſcoveries which have enriched the phyſic of the moderns may give it the preference to that of the ancients.

The phyſic of the ancients is perhaps to be preferred to that of the moderns, in being leſs profuſe of medicines in ſickneſs, and leſs deſirous to precipitate cures; in obſerving the motions of nature with more attention, and aſſiſting them with greater confidence; and in being contented to divide the honour of the cure with nature, without arrogating the whole glory of it to itſelf.

Phyſic, however uſeful and ſalutary, has had the misfortune of being made the butt of great men, eſpecially among the Romans. Cato declared himſelf moſt ſtrenuouſly againſt phyſicians, as we ſee in a letter to his ſon preſerved by Pliny; but it is to be obſerved that he means only the phyſicians from Greece. Pliny the naturaliſt was of much the ſame way of thinking, but his complaints extend only to perſons of no repute, authority, or learning.

Extremes are not to be admitted upon this head, in which blind confidence and ill-grounded contempt may be equally dangerous.

In ſhort, whether we conſider our bodies or our medicines, phyſic muſt be very precarious. Our bodies are more compounded and unequal than other bodies are; moſt other creatures live on a ſimple diet, and are regular in their appetites; whereas man feeds almoſt upon every thing, and, where appetite fails, invention is called in to ſwell the account by high ſauces and rich ſpices. Hence proceed ſuch variety of diſeaſes as diſtract the phyſician's ſkill. A healthy conſtitution is eaſily reſtored when out of order, nature in a great meaſure does its own work; whereas, in a diſordered body, a phyſician muſt give a new conſtitution before he can perfect the cure.

Though our materia medica be large enough, and to look into our diſpenſatories, one would think no diſeaſe incurable; yet the miſchief is, all thoſe fine medicines do not always anſwer in the application, nor have they been found ſo ſovereign in our bodies, as they are in our books: all which things have ſo diſtracted our phyſicians that they vary even in the moſt common method. In one age alkalies are in faſhion, and in the next acids begin to recover credit: bleeding is practiſed by one nation, and condemned by their neighbours, &c.

Medicine is divided into five principal branches: the firſt conſiders the human body, life, and health, and the effects flowing therefrom; this is called phyſiology, the doctrine of the œconomy or uſe of the parts; and its objects are called res naturales, or things according to nature.

The ſecond branch conſiders the diſeaſes of the human body, their differences, cauſes, and effects: as it conſiders diſeaſes, it is called pathology; as it enquires into the cauſes, ætiology; when it examines their differences, it is called noſology; and when it explains their effects, ſymptomatology. The objects of this branch are called res præternaturales, or beyond nature.

The third branch conſiders the ſigns or ſymptoms, and how to apply them to uſe; ſo as to judge both in a ſound and diſeaſed body what is or will be the degree, order, and effect of the health or diſeaſe. This is called ſemeiotica. Its objects are things both natural, non-natural, and preternatural.

The fourth branch conſiders the remedies and their uſe, whereby life may be preſerved; whence it is called hygieine. Its objects are what we ſtrictly call non-natural.

The fifth furniſhes the materia medica, its preparation and manner of exhibiting, ſo as to reſtore health; and is called therapeutica, comprizing the diætetica, pharmaceutica, chirurgica, and iatrica.

MEDICINES, *Medicamenta*, whatever ſubſtances ſerve to reſtore health.

MEDIETAS LINGUÆ, in law, ſignifies a jury, or

inqueſt impannelled, of which the one half are natives of this land, and the others foreigners.

MEDITULLIUM is uſed by anatomiſts for that ſpungy ſubſtance between the two plates of the cranium, and in the interſtices of all laminated bones. See the article DIPLOE.

MEDIUM, in logic, the mean or middle term of a ſyllogiſm, being an argument, reaſon, or conſideration for which we affirm or deny any thing; or, it is the cauſe why the greater extreme is affirmed or denied of the leſs in the concluſion.

MEDIUM, in philoſophy, that ſpace or region through which a body in motion paſſes to any point; thus æther is ſuppoſed to be the medium through which the heavenly bodies move; air, the medium wherein bodies move near our earth; water, the medium wherein fiſhes live and move; and glaſs is alſo a medium of light, as it affords it a free paſſage. That denſity or conſiſtence in the parts of the medium, whereby the motion of bodies in it is retarded, is called the reſiſtance of the medium, which together with the force of gravity, is the cauſe of the ceſſation of the motion of projectiles.

Subtile, or *Ætherial* MEDIUM. See ÆTHER.

MEDLAR, *Meſpilus*, in botany, &c. See the article MESPILUS.

MEDULLA, MARROW, in anatomy. See MARROW.

MEDULLA OBLONGATA, is the lower and medullary part of the cerebrum and cerebellum, formed into a kind of tail, and extended to the great foramen or hole in the occipital bone of the cranium, where it gives origin to the ſpinal marrow, and to the nerves of the brain. See the articles BRAIN and NERVE.

MEDULLA SPINALIS, or ſpinal marrow, is a continuation of the medulla oblongata of the brain, and forms, as it were, a tail to that part. It is included in a kind of bony canal, formed by the vertebræ, and in this is continued from the head to the extremity of the os ſacrum. Its length is therefore the ſame with that of the ſpina dorſi, which is different in perſons of different ſtature. Its thickneſs, in general, is nearly equal to that of a finger; but it is not uniformly of the ſame diameter throughout. Its ſubſtance, in the upper-part, as far as to the laſt vertebra of the thorax, is the ſame with that of the medulla oblongata of the brain, but ſomewhat tougher and more firm: they are externally of a medullary ſubſtance, that the nerves may eaſily make their way out; internally cineritious, and of the ſame nature with the cineritious or cortical part of the brain; but the lower part of them, from the laſt vertebra of the thorax to the extremity of the os ſacrum, is fibrous and very tenacious, and is called cauda equina. The diviſion of the ſpinal marrow is formed by means of a fiſſure; it is by this ſeparated into a right and left part, or into two columns; but this ſeparation is not continued to the center. Its proper integuments are no leſs than ſix: theſe are, 1. the bony canal, formed by the cavities of the twenty-four vertebræ, and the os ſacrum: 2. the tunica, which is very ſtrong, and connects the vertebræ within: 3. the cellular, or adipoſe coat, which, in fat perſons, always contains more or leſs fat, and ſeems deſtined by nature to ſoften the former: 4. the dura mater, which is ſtronger in the upper-part, and finer and weaker in the lower; this looſely incloſes the medulla in the ſpine, and in its anterior part, is firmly connected with the vertebræ: 5. the tunica arachnoides, which in its anterior part, adheres very firmly to the pia mater, but in its poſterior part is looſe and fluctuating: 6. the pia mater, which ſurrounds every part of the ſpinal marrow, and all the nerves that ariſe from it, and enters alſo its longitudinal diviſion. The arteries and veins of the ſpinal marrow enter at the apertures of the vertebræ, which give paſſage out to the nerves; they make a multitude of anaſtomoſes, and are derived from the vertebrals of the neck, the intercoſtals, and the lumbar. The nerves of the ſpine are thirty-one, or as others count them, thirty-two pair. Theſe are compoſed each of a multitude of fibres, ariſing from the anterior and poſterior parts of the medulla: theſe fibres afterwards unite, and are connected by and covered with membranes, and in that ſtate they conſtitute what we call nerves.

The uſes of the ſpinal marrow are, to give origin to the before-mentioned pairs of nerves, which are principally diſtributed to the limbs and external parts; and to ſecrete and prepare a nervous fluid.

MEDUSA's HEAD, in aſtronomy. See the article ALGOL.

MEI, or MISERERE MEI, in medicine. See the article MISERERE.

MEL, HONEY. See the article HONEY.

MELANCHOLY, in medicine, a ſpecies of madneſs, being a kind of delirium without a fever, uſually attended with fear, heavineſs, and ſorrow, without any apparent cauſe. It is infinitely varied according to the temperament and ideas of the perſon affected therewith. See MADNESS.

The word is Greek, μελαγχολια, and formed of μελας, black, and χολη, bile or gall.

The cauſes evidently productive of melancholy are obſerved to be,

1. All things which fix, exhauſt, or diſturb the nervous fluid of the brain; ſuch as violent and ſudden frights, intenſe thinking upon any ſubject, exceſſive love, watchings, ſolitude, fear, and hyſteric diſorders.

2. Such things as hinder and diſturb the generation, reparation, circulation, and various ſecretions and excretions of the blood, eſpecially in the ſpleen, ſtomach, omentum, pancreas, meſentery, inteſtines, liver, uterus, and hæmorrhoidal veſſels: ſo that, of conſequence, melancholy may be produced by the hypochondriacal diſorder; by acute diſeaſes ill cured, and eſpecially a phrenitis and burning fever; by an exceſs of all the ſecretions and excretions; by ſuch aliments and drinks as are cold, tenacious, terreſtrial, tart, and aſtringent; by violent heat long protracted and parching the blood; as alſo by a ſtagnant, moiſt, and cloudy air.

3. A naturally black, hairy, dry, ſlender, and robuſt conſtitution of body, a middle age, a quick, penetrating, and diſcerning genius.

If this diſorder continues long, it produces ſtupidity, epilepſies, apoplexies, madneſs, convulſions, blindneſs, ſurpriſing fancies, laughter, weeping, ſinging, ſighs, eructations, flatulences, anxieties; an urine ſometimes copious and limpid like water, and at others highly thick; a retention, accumulation of the excrementitious blood in the veſſels of the abdominal viſcera, and often a ſudden excretion of it; obſtinate coſtiveneſs, frequent ſpitting of a thin matter, and an incredible ability of enduring watchings, hunger, and cold.

This diſorder has often been cured by a ſupervening unſeemly itch, ſometimes reſembling an elephantiaſis; by numerous and large varices; by a copious diſcharge from the turgid hæmorrhoidal veins; and an evacuation of the black bile by vomit and ſtool.

Patients labouring under this diſorder are generally injured by all medicines which impair the ſtrength, and evacuate too forcibly; as alſo by thoſe which throw the humours into too violent commotions, whether cordials, or medicines of whatever other denomination.

Hence the beſt method of curing this diſorder is, after a due obſervation of the firſt cauſes and the variety of patients conſtitutions, to accommodate various medicines to theſe cauſes, and various conſtitutions.

The ſeveral intentions of cure to be purſued, therefore, are, 1. To rouſe, augment, and regulate the fluids of the brain and nerves; which is done, firſt, by diverting the mind from its uſual object to others of an oppoſite nature: ſecondly, by inducing cautiouſly another diſpoſition, or affection of mind, oppoſite to melancholy: thirdly, by humouring the perverſe and falſe turn of the imagination: or, fourthly, by frequently oppoſing it with great vigour.

2. To remove thoſe obſtructions which are either the cauſe, or the effect, of a perverted imagination, by ſoftening, inciding, and ſtimulating the obſtructing matter, by means of mineral waters, whey, viſceral, hepatic, and antihypochondriac decoctions, waters invigorated with fixed vial or compound ſalts, laxative preparations of mercury, emetics, motion, exerciſe, riding, ſailing, uterine medicines, and ſuch as promote the lochia, remedies which procure hæmorrhoidal diſcharges, baths, liniments, and plaſters.

3. To alleviate the ſymptoms by veneſection, im-

merſion

merſion in cold water, and the uſe of carminatives and opiates.

4. After due evacuations, to exhibit ſuch things as are from experience known to exhilarate the mind, and corroborate all the parts of the body.

From what has been ſaid, it is obvious that the perfect cure of this diſorder, as well as of great many others falſly accounted incurable, conſiſts in the correction of the bilis atra, or melancholic humour.

When melancholy increaſes ſo far as to bring on an agitation of the fluids of the brain, capable of driving the patient into a raging fury, the diſorder is called madneſs.

This only differs in degree from a dejected melancholy, is its offspring, ariſes from the ſame cauſes, and is generally to be cured by the ſame medicines.

In madneſs the muſcles are generally ſurpriſingly ſtrong, the patient is afflicted with watchings, incredibly capable of enduring hunger and cold, diſtracted by terrible imaginations, and ſubject to thoſe diſorders called lycanthropia and cynanthropia; which ſee.

It is obſervable, that, upon diſſecting thoſe who have died of madneſs, the brain has been found dry, hard, and friable, with its cortical ſubſtance of a yellow colour, and its veſſels turgid, varicoſe, and diſtended with black and viſcid blood.

It is alſo obſervable, that, during this diſorder, all the excretions have, in like manner, almoſt ceaſed.

Unexpected precipitation into the ſea, and a ſubmerſion in it, continued as long as poſſible, conſtitute the principal remedy for it.

Madneſſes, obſtinate againſt all remedies, have often been removed upon the approach of varices, hæmorrhoidal diſcharges, dyſenteries, dropſies, copious ſpontaneous hæmorrhages, tertian and quartan fevers.

Such a ſort of madneſs ſometimes ariſes after the body is, by an autumnal, violent, and long-continued intermittent fever, weakened and exhauſted, both by the force of the diſeaſe, and repeated veneſections and purgings. The madneſs is alſo generally brought on again by theſe very means.

This ſpecies of the diſorder is only to be cured by the uſe of reſtoratives, cardiacs, and corroboratives, long perſiſted in; but, if it is treated with evacuation, it brings on an atrophy, a weakneſs, and an unſurmountable fooliſhneſs.

But a madneſs ariſing in robuſt vigorous perſons in the flower of their age, or of hot and plethoric habits, is to be cured by repeated veneſections, interpoſing a briſk purge between each; and when the diſorder is alleviated, it is to be treated with opiates and cardiacs. *Boerhaave's Aphoriſms.*

MELANE, among phyſicians. See the article ALPHOS.

MELANTERIA, in natural hiſtory, a very beautiful foſſil, of a denſe, compact, and regular texture, and of an extremely bright pale yellow, reſembling nothing ſo much as the pureſt gold: it is remarkably heavy, and is uſually found in little irregular maſſes of the bigneſs of a pigeon's egg, which are broken with a ſlight blow; but it is uſually met with in the form of a fine gold-coloured efflorescence on vitriolic and pyritical bodies; or in looſe, ſhattery, and friable maſſes, of a more duſky yellow, in which latter ſtate, it ſo much reſembles a native ſulphur, that it is frequently miſtaken for one: however, it is not inflammable; but calcines in the fire to a greyiſh powder, which by burning longer changes to a deep and fine purple.

MELASSES, or MOLASSES. See the article MOLASSES.

MELCHITES, in church hiſtory, the name given to the Syriac, Egyptian, and other Chriſtians of the Levant. The Melchites, excepting ſome few points of little or no importance, which relate only to ceremonies and eccleſiaſtical diſcipline, are in every reſpect profeſſed Greeks; but they are governed by a particular patriarch, who reſides at Damas, and aſſumes the title of patriarch of Antioch.

MELCHIZEDECHIANS, in church hiſtory, a ſect which aroſe about the beginning of the third century, and affirmed, that Melchiſedech was not a man, but a heavenly power, ſuperior to Jeſus Chriſt; for Melchiſedech, they ſaid, was the interceſſor and mediator of the angels, but Jeſus Chriſt was ſo only for men, and his prieſthood only a copy of that of Melchiſedech. This hereſy was revived in Egypt by one Hierax, who pretended that Melchiſedech was the Holy Ghoſt.

MELEAGRIS, the turkey, in ornithology. See TURKEY.

MELES, the badger, in zoology. See the article BADGER.

MELIANTHUS, honey flower, in botany, a genus of plants, the flower of which conſiſts of four petals; and its fruit is a capſule with four cells, each containing a roundiſh ſeed.

MELICERES, in ſurgery, a kind of encyſted tumours, ſo called when their contents are of the conſiſtence of honey; but when this is of the conſiſtence of paſte, they are called a theromata.

MELILOT, *Melilotus*, in botany, a plant with ſmooth oval ſerrated leaves, ſtanding three together, on ſlender pedicles, and round, ſtriated, branched ſtalks, terminated by long ſpikes of papilionaceous flowers drooping downwards, which are followed by ſhort thick wrinkled pods, containing each one or two roundiſh ſeeds. It is annual or biennial, and found in flower, in hedges and corn-fields, greateſt part of the ſummer.

Melilot has been ſaid to be reſolvent, emollient, anodyne, and to participate of the virtues of chamomile. In its ſenſible qualities it differs very materially from that plant; its taſte is unpleaſant, ſabacrid, ſubſaline, but not bitter: when freſh, it has ſcarcely any ſmell; in drying, it acquires a pretty ſtrong one, of the aromatic kind, but not agreeable. The principal uſe of the plant has been in clyſters, fomentations, and other external applications: it formerly gave name to one of the officinal plaſters; which received from the melilot a green colour and an unpleaſant ſmell, without any addition to its efficacy.

MELISSA, baum, in botany. See the article BAUM.

MELODY, in muſic, the agreeable effect of different ſounds, ranged and diſpoſed in ſucceſſion; ſo that melody is the effect of a ſingle voice or inſtrument, by which it is diſtinguiſhed from harmony. See HARMONY.

MELON, in botany, makes a diſtinct genus of plants, the flowers of which conſiſt only of one leaf each, and are wide at the mouth, and divided into ſeveral ſegments, wholly reſembling the flowers of cucumbers. Of theſe alſo ſome are male or ſterile flowers, having no embryo fruit; others are fruitful or female flowers, having an embryo which ripens into a large fruit of an oval figure, ſometimes ſmooth, ſometimes rough, divided into three cells, and containing oblong ſeeds; each of theſe cells ſeems alſo divided into two.

The proper management and culture of melons is this: the ſeeds ſhould be procured from good melons, produced in ſome diſtant garden; for, if ſowed on the place where it was raiſed and ripened, it is very apt to degenerate. This ſeed ſhould be kept three years before it is ſowed, and it ſhould be ſowed at two ſeaſons. The firſt for the early crop, to be raiſed under frames, ſhould be ſown in January or the beginning of February; the ſecond, to be raiſed under bell or hand glaſſes, is to be ſowed in March, and this is the ſowing which produces the general crop of melons, which ripen in July and Auguſt. About a week before the time of ſowing the ſeed, ſome dung ſhould be prepared in a heap with the litter, or ſome coal aſhes, and the ſame methods uſed in the early cucumbers, for the firſt crop; but for the ſecond, which is of more general uſe, the ſowing may be on the upper ſides of the hot-beds that were for the early melons or cucumbers, or on a freſh moderate hot-bed. When the young plants are come up, they muſt be removed to another hot-bed, and covered with hand glaſſes, and watered and ſhaded till they have taken root; and after this, they muſt have as much air and ſun as the ſeaſon will permit, and their ſtalks ſhould be earthed up as they grow, which will vaſtly ſtrengthen them.

In the beginning of April the plants will begin to ſhew their rough leaves; a parcel of dung is then to be prepared with litter and coal aſhes. The common quantity is a load to five holes; a trench muſt then be dug, which

ſhould be ten inches deep, if the ſoil be dry, but only three, if it be wet. The dung muſt be evenly laid in this, and heaped up to three feet high; then the place intended for the holes muſt be marked out, at each of which muſt be laid a baſket full of light rich earth, thruſting a ſtick of two feet long into the middle. Then cover the dung all over with the earth, which was dug up out of the trench, laying it ſmooth, and about three inches thick; then the glaſſes are to be placed cloſe down over the place where each of the ſticks is, and in two days the earth will be warm enough to receive the ſeedling plants. The ſticks are now to be taken out, and the earth formed in the places into a hollow like a baſon, that it may retain the water which is given to the plants. The plants are then to be taken up, and two ſtrong and thriving ones put into each of theſe holes, which muſt be watered and ſhaded till they have taken root. The plants having taken root, and thruſt out a fourth leaf, the top of each of them ſhould be pulled off, in order to force out ſhoots from the bottom; and as the weather becomes warmer, the glaſſes muſt be raiſed with ſtones on the ſouth-ſide, to give them air, and about twice a week they ſhould have a little water.

About the middle of May the ſtalks of the plants will begin to preſs upon the glaſſes on every ſide, and the glaſſes are then to be raiſed up on bricks, to give them room to run out; and they ſhould be pegged down with forked ſticks, and turned into a proper direction for their running, ſo that they may be out of the way of tangling one with another: they ſhould now, if the weather be ſevere, be ſheltered with mats in the night, and watered gently at times. When the ſtalks of the plants are grown to the edges of the bed, the earth muſt be raiſed with old dung buried under it, till it be upon a level with the beds, for two feet wide on each ſide. The branches are here to be trained in a proper courſe, and the glaſſes are to be left over the roots of the plants; and after this, what water is given them is to be ſprinkled all over the plants. When the fruit begins to appear, the waterings muſt be very gentle on the plants; but it will be proper to ſoak the earth well with large quantities of water about the beds, which will ſpread a moiſture even to the roots of the plants; from this time the plants ſhould be gently watered twice a week, and that always in the evening. When the melons are grown of the ſize of a tennis ball, a piece of tile ſhould be laid under each to keep them from the ground. As they afterwards approach to ripeneſs, they ſhould be turned ſeveral times, that they may ripen equally every ſide; and if the weather be not very favourable, they ſhould be covered with glaſſes. If the melon is deſigned to be eaten as ſoon as cut, it ſhould be ſuffered to remain on the plant till it changes pretty yellow, and the ſtalk begins to ſeparate from the fruit; but if it is to be kept two or three days after cutting, it muſt be always cut proportionably earlier.

It is a practice with many to take off the leaves about the fruit, that it may have more ſun; but it is wrong, and the fruit is always the worſe taſted for it, and the ſkin is hard and tough. *Miller's Gard. Dict.*

When a melon is perfectly fine, it is full, without any vacuity: this is known by knocking upon it, and when cut the fleſh muſt be dry, no water running out, only a little dew, which is to be of a fine red colour. Large melons are not to be coveted, but firm and well-flavoured ones. Our gardeners, who raiſe melons for ſale, ſow the ſeeds of the large rather than the good kinds, and they increaſe the ſize of theſe by much watering the roots, but this ſpoils the taſte. Some of the French raiſe at this time particularly fine melons, by a method kept as a ſecret, but which we find, on a ſtrict enquiry, is no other than the ingenious Mr. Quintiny's, of that nation, publiſhed near eighty years ago in our Philoſophical Tranſactions.

The melons particularly proper to be treated in this manner, are thoſe which have a thin and ſomewhat embroidered ſkin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour.

MEMBRANE, in anatomy, a pliable texture of fibres, interwoven together in the ſame plane.

The membranes differ in thickneſs, according to the ſmallneſs of their fibres, or the number of their planes. Theſe particular planes are termed laminæ, and are diſtinguiſhed into internal, external, and middle. The difference of membranes, in general, depends on that of the fibres of which they are compoſed. Small portions of membranes, eſpecially when they are very thin, are called pellicles, and called the cellular or ſpongy ſubſtance.

MEMBRANOSUS, in anatomy, a muſcle otherwiſe called faſcia lata.

MEMOIRS, in matters of literature, a ſpecies of hiſtory, written by perſons who had ſome ſhare in the tranſactions they relate, anſwering to what the Romans called *commentarii*, commentaries.

MEMORY, *Memoria*, a faculty of the human mind, whereby it retains or keeps the ideas it has once perceived. See IDEA.

Memory, ſays Mr. Locke, is, as it were, the ſtore-houſe of our ideas; for the narrow mind of man not being capable of having many ideas under view at once, it was neceſſary to have a repoſitory in which to lay up thoſe ideas which it may afterwards have uſe of. But our ideas being nothing but actual perceptions in the mind, which ceaſe to be any thing where there is no perception of them; this laying up of our ideas in the repoſitory of the memory, ſignifies no more but this; that the mind has a power, in many caſes, to revive perceptions it has once had, with this additional perception annexed to them, that it has had them before. And it is by the aſſiſtance of this faculty, that we are ſaid to have all thoſe ideas in our underſtandings which we can bring in ſight, and make the ſubjects of our thoughts, without the help of thoſe ſenſible qualities which firſt imprinted them there.

Attention and repetition help much to the fixing ideas in our memories: but thoſe which make the deepeſt and moſt laſting impreſſions, are thoſe which are accompanied with pleaſure and pain. Ideas but once taken in and never again repeated, are ſoon loſt; as thoſe of colours in ſuch as loſt their ſight when very young.

The memory of ſome men is tenacious even to a miracle: but yet there ſeems to be a conſtant decay of all our ideas, even of thoſe which are ſtruck deepeſt; and in minds the moſt retentive: ſo that if they be not ſometimes renewed, the print wears out, and at laſt there remains nothing to be ſeen.

Thoſe ideas that are often refreſhed by a frequent return of the objects or actions that produce them, fix themſelves beſt in the memory, and remain longeſt there: ſuch are the original qualities of bodies, viz. ſolidity, extenſion, figure, motion, &c. and thoſe that almoſt conſtantly affect us, as heat and cold.

In memory, the mind is oftentimes more than barely paſſive; for it often ſets itſelf on work to ſearch ſome hidden ideas; ſometimes they ſtart of their own accord; and ſometimes tempeſtuous paſſions tumble them out of their cells. This faculty other animals ſeem to have to a great degree, as well as men, as appears by birds learning of tunes, and their endeavour to hit the notes right. For it ſeems impoſſible that they ſhould endeavour to conform their voices, as it is plain they do, to notes whereof they have no idea.

Local MEMORY, among orators, is nothing but the aſſociating the different heads to be handled, with the objects before the ſpeaker's eyes; ſo that by only looking around him, he is put in mind of what he is to ſay.

Artificial MEMORY, *Memoria Technica*, a method of aſſiſting the memory, by forming certain words, the letters of which ſhall ſignify the date or æra to be remembered.

MENDICANTS, or begging friars, ſeveral orders of religious in Popiſh countries, who having no ſettled revenues are ſupported by the charitable contributions they receive from others.

MENIALS, in law books, domeſtic or houſhold-ſervants, who live under their lord or maſter's roof.

MENINGES, or MENYNGES, in anatomy, a name given to the dura and pia mater of the brain.

MENIPPEAN, in poetry, a kind of ſatire, conſiſting of proſe and verſe intermixed.

MENISCUS, in optics, a lens convex on one ſide, and concave on the other. See LENS.

For finding the focus of a meniſcus, the rule is, as the difference of the ſemi-diameters of the concavity and convexity, to the ſemi diameter of the concavity; ſo is the diameter of the convexity to the focal diſtance.

MENNONITES, a ſect of baptiſts in Holland, ſo called from Mennon Simonis of Friezeland, who lived in the ſixteenth century. This ſect believe, that the New Teſtament is the only rule of faith; that the terms perſon and Trinity are not to be uſed in ſpeaking of the Father, Son, and Holy Ghoſt; that the firſt man was not created perfect; that it is unlawful to ſwear, or to wage war upon any occaſion; that infants are not the proper ſubjects of baptiſm; and, that miniſters of the Goſpel ought to receive no ſalary.

MENOLOGY, the Greek calendar, in which the lives of the ſaints in ſhort, or barely their names, are cited; anſwering nearly to the martyrology of the Latin church.

MENSALS, *Menſalia*, in church hiſtory, ſuch livings as were formerly united to the tables of religious houſes, and hence called menſal benefices.

MENSES, *Catamenia*, fluors, courſes, in medicine, are the monthly evacuations from the uterus of women not with child, and not giving ſuck.

The word is derived from the Latin *menſis*, a month, the period wherein they generally return.

The common cauſe of the ſtoppage of the menſtrual diſcharges is the blood's lentor; whereby this fluid becomes incapable of forcing the ſphincters of the ducts deſtined by nature for this evacuation. For it is not from the burſted arteries of the uterus, which is the common opinion, that the blood iſſues every month, but from veſſels peculiarly appropriated to this office. And this lentor or thickneſs of the blood changes the lively colour of the face into a greeniſh pale, and wan complexion.

The proper medicines, in this diſtemper, are thoſe which are capable of increaſing the blood's circulation, and attenuating the viſcid humours: and ſuch are all bitters, joined with aromatics, as alſo many preparations of ſteel. But to theſe ought to be premiſed blood-letting, and cathartics blended with calomel. The tinctura ſacra is alſo an excellent medicine.

But of all the moſt powerful emmenagogues, I have found ſo ſingular virtue in black hellebore, that I hardly remember it ever failed anſwering my expectations. My way of ordering it is, a tea-ſpoonful of tincture of black hellebore in a glaſs of warm water, to be taken twice a day. And I have obſerved this remarkable circumſtance, that whenever, either from a bad conformation of the parts, or any other cauſe, this medicine had not the deſired effect, the blood was forced through ſome other paſſages; which is a manifeſt proof of the great power of this medicine in ſpurring the blood forward.

But likewiſe the menſtrual diſcharges frequently run to exceſs. In that caſe the flux is to be reſtrained; which, after letting blood, is effected both by thoſe medicines which condenſe and inſpiſſate the blood, and by thoſe which allay its heat. Of the firſt ſort, the principal are ſuch as participate of vitriol or alum; eſpecially the tincture of roſes; or a powder compoſed of alum three parts, and dragon's-blood one part, melted together. But the heat of the blood, and its conſequence, the flux, is more powerfully checked by the Peruvian bark, than by any other medicine whatſoever. *Mead.*

MENSTRUUM, or DISSOLVENT, in chemiſtry, a body which, when artificially applied to another, divides its ſubtility, ſo that the particles of the ſolvent remain thoroughly intermixed with thoſe of the ſolvend.

It was called a menſtruum, becauſe the chemiſts, in its application to the ſolvend, firſt uſed a moderate fire, for a philoſophical month, or forty days; and hence aroſe the name of menſtrual ſolvent, at length barely a menſtruum.

It is the property of a menſtruum to be itſelf equally diſſolved, when it diſſolves the ſolvend; but when the ſolution is perfected, it may ſometimes happen that the ſolvent and ſolvend ſhall ſeparate. The divided parts, therefore, of the ſolvent, muſt inſinuate itſelf among the parts of the ſolvend, ſo as to divide and diſſolve the body. Hence it appears, that the actions of menſtruums differ from all mechanical ſeparations, where the inſtrument, ſuch as a knife, ſword, or ſaw, while it divides, is not itſelf divided, but remains almoſt entire. But there is ſome reaſon to ſuſpect, that the ſingle particles of a menſtruum act like mechanical inſtruments, by the properties of their own proper ſize, figure, hardneſs, and gravity. Every menſtruum, while it diſſolves, is neceſſarily divided into inviſible particles, and muſt therefore be fluid in the action; and when the diſſolution is completed, the ſolvent and ſolvend muſt become one fluid.

Cuſtom has given the name of menſtruums to many bodies of a hard and conſiſtent nature, though in that ſtate they cannot act as ſolvents; and hence the chemiſts have divided menſtruums into ſolid and fluid.

Dry or ſolid menſtruums may be again divided into five claſſes, which, according to Boerhaave, are as follow: 1. The ſix metals, gold, lead, ſilver, copper, iron, and tin, which act upon one another after being fuſed in the fire, and may be intimately mixed, ſo as to make an apparently homogeneous maſs, every particle of which holds the ſame proportion of a different metal as the whole: for if ten ounces of ſilver be thus mixed with an ounce of gold, and a grain of this maſs be given to an aſſay-maſter, he will diſcover that it contains one eleventh part gold, and ten parts ſilver. 2. The ſemi-metals, as antimony, biſmuth, cinnabar, marcaſites, and zinc, which, when melted, mix with one another or with metals; but when thus mixed they are no longer malleable, but may eaſily be reduced to powder. 3. The dry ſalts, as alum, borax, nitre, ſal-ammoniac, ſea-ſalt, vitriol, fixed alkali, and mercury ſublimate, which may be ſubtilly divided by fire, and intimately mix with one another, with metals, ſemi-metals, and other things. 4. Hard foſſile ſulphureous bodies, as ſulphur vivum, common brimſtone, arſenic, orpiment and cobalt. 5. The foſſile bodies, called by refiners cements, which conſiſt of ſalts, ſulphur, and brick, reduced to dry powders, and ſtrewed betwixt plates of metals, in order to raiſe their colour, or ſeparate one metal from another.

Some menſtruums being left to themſelves, after ſolution concrete into a hard maſs, which, though compounded, appears of an uniform ſimple nature. In this manner, if melted lead be mixed with tin, they unite, as water with water, or mercury with mercury. The caſe is the ſame in all the metals, and in ſome of the ſemi-metals. Thus if a ſcruple of regulus of antimony be added to a pound of melted tin, the maſs when cold will appear uniform, but become entirely brittle; ſo fixed alkali unites with ſand in the fire; and ſulphur and mercury, by being ground together, turn to a black and dry powder, which being ſublimed produces an apparent ſimple body, called cinnabar. Many become an hard, and ſometimes a dry body. Thus almoſt all the menſtruums of metals unite with their reſpective metals into ſolid vitriols: and thus ſtrong diſtilled vinegar, when it has diſſolved ſhells, chalk, and ſtony ſubſtances, ſeparates from its water, and together with the body it diſſolves, forms a dry hard maſs.

Numerous menſtruums have a liquid form before they act as ſolvents; as vinegar, water, ſaline, acid, alcaline and compounded ſpirits, alcaline oils per deliquium, &c. Some menſtruums become liquid after the ſolution, and continue ſo with the ſolvent. Thus in the diſſolution of five of the metals with ſimple mercury a ſoft paſte is produced, which may indefinitely be diluted by the addition of more mercury; but there is ſcarcely any known method of reſtoring this amalgama to its ſolidity. All the liquid menſtruums, after having diſſolved metals in a large proportion, cannot eaſily be dried; whence many have imagined theſe ſolutions to be fixed metallic oils, and in vain ſought ſecrets in them.

It is now eaſy to obſerve that many menſtruums unite bodies as well as ſeparate them; for frequently after the diſſolution the particles of the menſtruum preſently join with thoſe of the ſolvent, and produce a new compound, often very different from the nature of the ſimple reſolved body. The parts however of the ſolvent, after its concretion, no longer touch one another, but are ſeparated by the interpoſition of the particles of the matter diſſolved; and the particles which before conſtituted the ſolvend are ſeparated by the interpoſition of the particles of the ſolvent.

Hence it is plain that the parts of the menſtruums apply themſelves to the parts of the ſolvend; and a certain cauſe is here required to make the particles of the ſolvent fly from one another and approach the particles of the ſolvend, rather than remain in their former ſituation. The like cauſe ſeems to be required to make the particles of the ſolvend, now ſeparated, remain united with the parts of the menſtruum, rather than ſuffer the diſſolving and diſſolved particles to unite by their natural affinity into homogeneous bodies. This cauſe muſt be ſought in the ſolvend as well as in the ſolvent, for the action is reciprocal. Thus while aqua regia diſſolves thrice its weight of gold into a yellow liquor, the particles of gold are united with the aqua regia, and remain ſuſpended in it, though gold be eighteen times heavier than aqua regia. Whence there muſt be a mutual correſponding power between the particles of the gold and aqua regia, whereby they act upon, embrace and detain each other, otherwiſe the particles of gold would fall to the bottom, the ſaline particles reſt upon them, and the water float over both. If we were to deduce the cauſe from ſimilitude of ſubſtance, the action of diſſolution ſeems to be performed by a certain power of the parts of the menſtruum to attract the diſſolved parts rather than to repel them; and is not a mechanical action, or unfriendly commotion, but rather an appetite of union. Thus, in a violent ſolution, the agitation, heat, hiſſing and tumult ceaſe when all the parts of the ſolvend have united with thoſe of the ſolvent, as appears in throwing a piece of iron into weak aqua-fortis.

The whole ſolvent never acts at once on the whole ſolvend, only thoſe particles of the ſolvent which touch ſome others of the ſolvend act firſt; and theſe being ſeparated, freſh particles of the menſtruum apply themſelves to others of the ſolvend: therefore part of the menſtruum acts upon that part of the body which it ſtrikes off and ſeparates; but the conflict made in this ſeparation excites a greater motion in the menſtruum, by which means other parts of the menſtruums are agitated and applied to other parts of the ſolvend.

Fire excites, promotes, and increaſes the action of menſtruums; for in extreme cold ſolutions are either not made or made but ſlowly, but they are ſoon performed by the aſſiſtance of heat: ſome menſtruums require a ſtrong heat, as mercury, before it will diſſolve metals: ſome a ſmaller; thus ſal armoniac, ſea ſalt, and ſalt of tartar eaſily diſſolve in water: ſome menſtruums act with a moderate heat, but loſe their diſſolving power, or even acquire a power of coagulating, by a ſtronger; thus warm water diſſolves the white of eggs, which boiling coagulates. This effect of fire ſeems to be produced, 1. by impelling, moving and agitating the menſtruum in the manner of a mere mechanical motion. 2. By its general power of expanding the ſubſtance of all bodies. 3. By ſeparating the parts ſo as to ſet them farther aſunder. In moſt caſes the heat is increaſed during the ſolution, and even the action of thoſe menſtruums is augmented by heat, which generate a great degree of cold in the ſolution; thus ſal ammoniac diſſolves ſooneſt in warm water.

Sir Iſaac Newton accounts for the action of menſtruums, from the acids wherewith they are impregnated, which are found to be endued with a ſtrong attractive force, wherein their activity conſiſts. See ACID.

MENSTRUUM, in pharmacy, chiefly denotes a body that will extract the virtues of ingredients by fuſion, decoction, &c.

MENSTRUUM *Peracutum*, a menſtruum which Mr. Boyle extracted from bread only, that would prey even on glaſs, and perform many things which aqua-fortis would not.

With this he drew tinctures from coral, lapis hæmatites, granates, diamonds, and rubies.

Univerſal MENSTRUUM. See ALKAHEST.

MENSURATION, *Menſuratio*, in general, denotes the act or art of meaſuring lines, ſuperficies, or ſolids.

MENTHA, mint, in botany, a perennial herb, with ſquare ſtalks, ſerrated undivided leaves ſet in pairs; and ſpikes of monopetalous flowers, each of which is cut into four ſections, and followed by four ſeeds incloſed in the cup.

MENTHA *Vulgaris*, mint, hartmint, ſpearmint, with oblong, narrow, pointed leaves, joined cloſe to the ſtalk; and ſmall purpliſh flowers ſtanding in long ſpikes on the tops. It is a native of the warmer climates, common in our gardens, and flowers in June and July.

This herb has a ſtrong agreeable aromatic ſmell, and a bitteriſh, roughiſh, moderately warm taſte. It is in general uſe as a reſtringent, ſtomachic, and carminative: in vomitings and weakneſs of the ſtomach, there are perhaps few ſimples of equal efficacy.

MENTHA *Piperitis*, pepper-mint, with acuminated leaves on very ſhort pedicles; and the flowers ſet in ſhort thick ſpikes or heads. It is a native of this kingdom; and ſo far as is known, of this kingdom only: it has of late been received into general practice as a medicine, and is now raiſed plentifully in gardens, and does not appear to loſe any thing of its virtue with the change of ſoil.

This ſpecies of mint has a very penetrating ſmell, a ſtrong and warm taſte, pungent and glowing like pepper, and ſinking as it were into the tongue. It is a medicine of great importance in flatulent colics, hyſteric depreſſions, and other like complaints; exerting its activity as ſoon as taken into the ſtomach, and diffuſing a glowing warmth through the whole ſyſtem; yet not liable to heat the conſtitution near ſo much as might be expected from the great warmth and pungency of its taſte.

By maceration or infuſion, it readily and ſtrongly impregnates both water and ſpirit with its virtue; tinging the former of a browniſh colour, and the latter of a deep green. In diſtillation with water it yields a conſiderable quantity of eſſential oil, of a pale greeniſh yellow colour, growing darker-coloured by age, very light, ſubtile, poſſeſſing in a high degree the ſpecific ſmell and penetrating pungency of the pepper-mint; the decoction remaining after the ſeparation of this active principle, is only bitteriſh and ſubaſtringent, like thoſe of the other mints. Rectified ſpirit, drawn off with a gentle heat from the tincture made in that menſtruum, brings over little of the virtue of the herb, nearly all its pungency and warmth remaining concentrated in the extract, the quantity of which amounts to about one fourth of the dried leaves.

MERCATOR's CHART, a projection of the earth's ſuperficies in plano, where the meridians are ſtraight lines, parallel to, and equidiſtant from each other. The parallels of latitude are alſo ſtraight lines, and parallel to one another, but the diſtance between them increaſes from the equinoctial towards either pole, in the ratio of the ſecant of the latitude to the radius.

If the ſuperficies of the terreſtrial globe be ſuppoſed to be taken off, and extended on a plane, ſo as to make the meridians parallel to each other, and the degrees of longitude every where equal, it is eaſy to conceive that it muſt be productive of moſt notorious errors; for an iſland in latitude 60°, where the radius of the parallel is only equal to one half of the radius of the equator, will have its length from eaſt to weſt diſtorted in a double ratio to what it was on the globe; that is, its length from eaſt to weſt, in compariſon of its breadth from north to ſouth, will be repreſented in a double proportion to what it really is; whence it follows, that in whatever proportion the degrees of any parallel are increaſed or diminiſhed, by a projection in plano, the degrees of longitude ought to be increaſed or diminiſhed in the ſame ratio; for otherwiſe the true bearings and diſtances of places will be loſt, as in the caſe of the plain-chart, where the degrees of latitude and longitude are all equal.

Though this projection is generally called Mercator's projection, yet our countryman, Mr. Wright, had long before invented it, demonſtrated its uſe, and ſhewn a ready way of conſtructing it, by enlarging the meridian line by a continued addition of ſecants; but neither of theſe gentlemen is thought the original author of it, as being hinted by Ptolemy about two thouſand years ago.

The Manner of conſtructing MERCATOR's *Chart.*—Let AB (plate LXXXVII. *fig.* 1.) be an arch of the equator, intercepted between any two meridians as AP, BP, meeting in P, the pole of the ſphere, whoſe center is C. Upon the points A and B, erect the perpendiculars AH and BI, and let DE repreſent an arch of any parallel contained between the ſame meridians. Draw CA and CB, KD and KE, perpendicular to PC; through D and

and E draw C F, C G, and join F G; laſtly, let fall the perpendicular D L.

Now the arch of the equator A B is to the ſimilar arch of the parallel D E, as A C is to D K, or as the radius to the co-ſine of the latitude A D. Suppoſe now the meridians A P, B P, to be in the part projected into the perpendiculars A H and B I, then will the arch D E be projected into the arch F G = A B; but in this caſe D E, the natural length of the arch, is to F G, its protracted length, as the radius C D to the ſecant of the latitude C F, or as the co-ſine L C to the radius C D; for as C F : A C = C D :: D C : L C. Hence it follows, that the degrees of latitude in Mercator's chart, increaſe in proportion of the ſecant of the latitude to the radius. Let us now project a chart on theſe principles; in order to which, draw the line A B, (plate LXXXVI. *fig.* 1.) and divide it into as many degrees as your map is to contain in longitude, ſuppoſe 90°. At the extremities A and B raiſe perpendiculars, to which draw parallel lines at every ſingle, fifth, or tenth degree of the equator for the meridians; as in the figure, where they are drawn at every tenth degree. This done, put one foot of the compaſſes in the point A, and extending the other to the point in the firſt meridian in the equator G; or, for greater exactneſs, to ſome more diſtant point, as B 90; deſcribe the quadrant F B, which divide into nine equal parts, and draw lines from A to each point of the diviſion; or, to avoid ſcoring the paper, only mark where a ruler cuts the firſt meridian G H, at every tenth degree's diſtance. Laſtly, becauſe the diſtances of the parallels from one another are marked, by this means, in the line G H, you muſt tranſfer them from that line to the ſide lines A C, B D, after the following manner. 1. Set one foot of the compaſſes in A, and extending the other to the firſt point above G, marked 1, tranſfer this diſtance, viz. A 1, to the lines A C, B D, and draw a line parallel to the equator A B, for the tenth parallel. 2. Next tranſfer the diſtance A 2 into the lines A C, B D, from the tenth parallel to the twentieth, which is to be drawn. 3. In the ſame manner the diſtances A 3, A 4, A 5, &c. laid off upon the lines A C, B D, from the immediately preceding parallels, viz. 20, 30, 40, &c. will ſucceſſively point out where the parallels 30, 40, 50, &c. are to be drawn.

MERCATOR's *Sailing*. See *Mercator*'s SAILING.

MERCHANT, a perſon who buys and ſells commodities in groſs, or deals in exchanges; or that traffics in the way of commerce, either by importation or exportation. Formerly every one who was a buyer or ſeller in the retail way, was called a merchant, as they are ſtill both in France and Holland; but here ſhop-keepers, or thoſe who attend fairs or markets, have loſt that appellation.

MERCURIAL, ſomething conſiſting of, or relating to mercury.

MERCURIFICATION, in chemiſtry, the method of ſeparating the mercuries of metals, which is moſt eaſily effected by means of a burning-glaſs; for the metal being placed in its focus, its mercurial parts are ſaid to fly off in ſmoke, which when condenſed and collected, appears to be true quickſilver.

MERCURY, in natural hiſtory, a fluid metallic ſubſtance, not moiſtening the hands; perfectly opake; of a bright ſilver colour, reſembling lead or tin when melted; entirely void of taſte and ſmell; extremely diviſible; not congealable in the greateſt degree of natural cold.

It is the moſt ponderous of all fluids, and of all known bodies except gold and platina: its gravity is to that of water nearly as 14 to 1; a cubic foot of quickſilver weighing 947 pounds, whilſt a cubic foot of water weighs but 70: it is found to be heavier in winter than in ſummer, in the proportion of eleven ounces thirty-two grains, to eleven ounces ſeven grains. In conſequence of its great denſity, it is of all fluids the coldeſt to the touch: the hand cannot be kept one quarter of an hour in a quantity of quickſilver with ſafety. Of all fluids likewiſe it grows hotteſt, not really, but apparently, from the application of an equal external heat.

In a heat below ignition, it totally exhales in extremely thin, ſubtile, penetrating fumes, which condenſe into running mercury again: the admiſſion of air, which changes the fumes of the other ſemi-metals into a powdery calx, has not that effect upon thoſe of quickſilver.

It diſſolves in all the mineral acids, but with different degrees of facility; and proves itſelf a menſtruum for ſundry metallic bodies. It has the greateſt affinity with gold; adhering to and diſſolving that metal the moſt readily of all. It unites eaſily alſo with ſilver; leſs eaſily with lead; ſtill leſs ſo with tin; very difficultly with copper; moſt difficultly of all with iron, to which it ſeems to have an inſuperable repugnance. It does not eaſily take up biſmuth or regulus of antimony, unleſs they are previouſly mingled with other metals, or diſpoſed to unite with it by particular managements; after it has been combined with either of theſe, it throws them out again upon digeſtion; biſmuth nevertheleſs diſpoſes ſome other metals, particularly lead, to ſuch an intimate union with the mercury, as to paſs along with it through the pores of leather. Quickſilver mingles alſo with various ſaline ſubſtances, and with ſulphur; with which laſt it forms a black maſs called æthiops, which changes, on ſublimation, into a red one called cinnabar.

There are different methods of purifying quickſilver; as ſtraining through leather; trituration or ablution with vinegar; with vinegar and ſalt, with ſope-leys, with rectified ſpirit of wine, and with aqua-fortis; and diſtillation, either without addition, or with alkaline ſalts, quick-lime, or iron filings. When quickſilver is only ſuperficially mixed with duſt or earthy powders, ſtraining thro' leather is ſufficient for its purification: if any foulneſs ſtill remains, ſpirit of wine will waſh it off: unctuous or oily impurities require ablution with ſope-leys. Lead and biſmuth are moſt effectually ſeparated by making the mercury into an æthiops, with a ſufficient quantity of ſulphur, and reviving it again from the æthiops by diſtillation, with twice its quantity of quicklime, alkaline ſalt, or iron filings; the mercury alone will diſtil, and leave all its impurities behind; ſulphureous, antimonial, and other like admixtures, are to be ſeparated by the ſame means. The purification by aqua-fortis is performed by taking only a ſmall quantity of the acid to a large one of mercury; grinding them diligently together, and then waſhing the quickſilver with water. When mercury is combined with ſulphur into cinnabar, the revivification of it does not well ſucceed with alkaline ſalts; by fixed alkalies, the ſulphur is very difficultly, and not perfectly abſorbed; to volatile alkalies it does not yield at all: on the other hand it is obſervable, that metallic bodies, as iron, lead, tin, regulus of antimony, readily detain the ſulphur in diſtillation, and ſuffer the mercury to ariſe pure.

The largeſt quantities of mercury are employed for metallurgical operations: gold and ſilver are extracted, in the Spaniſh Weſt Indies, from their ores or matrices, by amalgamation with mercury; and both metals are recovered by the ſame means, when blended in minute particles with earthy matters, as in filing or working them. Amalgamated with tin, it makes the foil for looking-glaſſes, and reflecting balls. It is uſed alſo for gilding on ſilver, for anatomical injections, for weather glaſſes, and ſundry other purpoſes. In vacuo, it appears luminous, and is then called the mercurical phoſphorus.

Quickſilver, conſidered as a medicine, is a ſpecific againſt the venereal diſeaſe, worms, lice, and all kinds of inſects: the venereal diſtemper is not perhaps to be radically cured without it, but againſt inſects there are other remedies equally if not more effectual. It is commonly ſuppoſed to have, of itſelf, no poiſonous quality; but it appears, from experience, manifeſtly prejudicial to the nerves and the bones. Its ill effects are moſt obſervable in thoſe, who are expoſed to its fumes; which fumes are no other than perfect quickſilver, as any one may be convinced by receiving them on a piece of moiſt leather or cloth, upon which they will reunite into little globules of mercury. Moſt people admit a pernicious quality in the fumes, though they deny it to the quickſilver; not conſidering that the fumes are only the quickſilver itſelf, divided but not altered by the heat. Even mercurial ointments applied externally have occaſioned contractions of the limbs, corroſions of the bones, and other dangerous conſequences. How ſoon do the miners feel its ill effects, though they neither anoint with it, nor ſwallow it, nor are expoſed to the fumes into

which

which it is reſolved by fire! They firſt become paralytic, and fall afterwards into a ſalivation: their teeth drop out: violent pains in the whole body, particularly in the bones, and at length death, ſucceed. It may be proper to obſerve, that the Spaniſh phyſicians treat theſe patients in a different method from that purſued among us and in other countries: they expoſe them frequently for a conſiderable length of time to the open air, and give internally nothing but abſorbents.

Quickſilver, included in a flat-bottomed glaſs, having a ſmall hole open to the air, and kept for ſeveral months in a conſtant heat juſt not ſtrong enough to make it evaporate, calcines by degrees into a red powder, called mercurius calcinatus. A greater heat, ſufficient to make the mercury diſtil, does not only promote the calcination, but revives ſuch part as has been already calcined, into running mercury again. A weaker heat, as that of the human body, or even of boiling water, though continued for years, changes only a ſmall part of the mercury into a blackiſh powder; conſtant triture or agitation produces ſimilar effects to this low degree of heat, and in a much ſhorter time. If the free acceſs of air ſhould be found to influence the calcination of this, as it does that of the metallic bodies called imperfect, the tedious proceſs might be expedited, by uſing, for the veſſel, a glaſs tube, with both its ends bent upwards, and one of them conſiderably higher than the other; through which, a conſtant ſtream of freſh air would paſs over the ſurface of the ſmall thread of mercury at the bottom.

This red powder has by ſome been greatly eſteemed in venereal caſes, and ſuppoſed to be the moſt effectual and certain of the mercurials. It is accompanied with one conſiderable inconvenience, being greatly diſpoſed to irritate the firſt paſſages, and occaſion gripes; to prevent which, a ſmall quantity of opium, and ſome warm aromatic material, are commonly joined to it: the antivenereal pills of a late celebrated empyric are ſuppoſed to have been a compoſition of this kind. Even when thus corrected, however, it does not appear to have any advantage above the mercurials in common uſe and of eaſier preparation. The doſe is from half a grain to two grains: five or ſix grains are ſaid to vomit and purge violently.

The blackiſh powder, obtained by long agitation, is the baſis of an antivenereal medicine, which has lately come into great repute abroad; but which appears, from the accounts publiſhed of it in France, to be neither ſo ſafe, nor ſo effectual, as ſome of the common officinal mercurials.

If oil of vitriol be poured on half, or equal, its weight of quickſilver, and gradually heated till the liquor boils and diſtils; the more phlegmatic parts ariſe, while the ſtronger acid corrodes the mercury into a white cauſtic maſs. On the affuſion of warm water, the maſs falls into powder, and becomes immediately yellow; a part of it, ſatiated with acid, diſſolving in the water: the larger the quantity of acid made uſe of, and the leſs thoroughly the matter has been exſiccated or calcined, the more of it will diſſolve. The yellow powder, ground with freſh quantities of water till all the ſoluble part is extracted, becomes inſipid, and in this ſtate, commonly called turpeth or turbith mineral, it proves, tho' not corroſive, ſtrongly emetic; operating, in this intention, the moſt effectually of all the mercurials that can be given with ſafety. It is uſed chiefly in violent gonorrhœas, and other venereal caſes accompanied with a great flux of humours to the parts: it is ſaid likewiſe to have been employed with ſucceſs, in robuſt conſtitutions, againſt leprous diſorders, and obſtinate glandular obſtructions. The doſe, as an emetic, is from two grains to ſix or eight; though ſome conſtitutions, habituated to mercurials, can bear larger quantities. It may be given in ſmaller doſes, as half a grain or a grain, as an alterative, after the ſame manner as the red calx of mercury already mentioned: and even when intended as an evacuant, it may perhaps, as Malouin obſerves, be moſt adviſable, to give only a ſmall quantity at a time, as one grain, and repeat this doſe every hour till the vomiting ſucceeds.

On adding a ſolution of ſea-ſalt to a ſolution of mercury made in aqua-fortis, the nitrous acid quits the mercury, and unites with the alkaline baſis of the ſea-ſalt; and at the ſame time, the acid of the ſea-ſalt unites with the mercury, and forms with it a compound, difficultly, and only partially diſſoluble, of which therefore great part ſubſides, on ſtanding for ſome time, in form of a white powder. This powder, waſhed with freſh quantities of hot water, till the more ſoluble parts are extracted, becomes nearly inſipid. In this ſtate it is recommended by Boerhaave as one of the beſt of the mercurials, and ſaid, in doſes of three grains, to purge and vomit gently. It appears however too corroſive for internal uſe; being ſo much ſo, as to be employed by the farriers for the purpoſes of an eſcharotic. The preparation is likewiſe a very unfrugal one, a conſiderable part of the mercury remaining unprecipitated, and a conſiderable part of the precipitate being diſſolved and carried off in the ablution.

Spirit of ſal ammoniac, or other volatile alkalies, dropped into a filtered ſolution of ſublimate, abſorb a part of the acid; and the mercury, retaining ſo little as to be indiſſoluble, renders the liquor milky, and ſubſides on ſtanding, in form of a fine white powder, which, waſhed by repeated affuſions of hot water, becomes inſipid. Solutions of fixed alkaline ſalts, ſubſtituted to the volatile ſpirit, produce a yellow precipitation; but if an equal weight of crude ſal ammoniac be diſſolved along with the ſublimate, fixed alkalies, added to this ſolution, extricate the volatile alkali of the ſal ammoniac, and the precipitate proves the ſame as if the volatile alkali alone had been added in its pure ſtate. Theſe precipitates are uſed chiefly on account of the elegance of their colour, in unguents for cutaneous eruptions; one part of the mercurial precipitate, three of precipitate ſulphur, and eighteen of the ſimple ointment or pomatum, moiſtened with a little ſtrong alkaline ley, make the common mercurial application for theſe complaints. The precipitates have been given internally; but mercurius dulcis, which differs from them only in being more mild, and more equal and certain in its effects, is in this intention greatly to be preferred. It does not appear that a combination of mercury, with ſo ſmall a proportion of acid, that is, ſo mild and ſafe a mercurial, can be obtained by any kind of precipitation, as by the proceſs by which mercurius dulcis is prepared.

Mercurius dulcis is ſublimate made mild, by combining with it ſo much freſh mercury, as is ſufficient to ſatiate the redundant acid. Four parts of powdered ſublimate are ground with three of quickſilver, an operation in which great caution is neceſſary, to avoid the lighter corroſive particles that fly off, till they are thoroughly incorporated; or, which is much more commodious, digeſted together in a gentle heat, by which the union will be performed as effectually. The mixture is then ſublimed in a glaſs matraſs or phial; the ſublimed maſs freed from the whitiſh acrid matter about the mouth of the veſſel, and from ſuch mercurial globules as may happen to appear diſtinct, then pulveriſed, and ſublimed again: in this manner the ſublimation is repeated ſix times, by which means the medicine becomes leſs liable to irritate the firſt paſſages, and run off by ſtool.

Mercurius dulcis ſeems to be the beſt and ſafeſt of the mercurial preparations that can be taken in a ſolid form. It may be given from fifteen to twenty grains; or, as an alterative, from one to two or three grains.

MERCURY ☿, in aſtronomy, the ſmalleſt of the inferior planets, and the neareſt to the ſun. See the article PLANET.

According to Mr. Caſſini, the greateſt diſtance of Mercury from the earth is 32704, the mean diſtance 22000, and the leaſt diſtance 11296 ſemi-diameters of the earth: therefore his mean diſtance will be about 88000000 Engliſh miles; and the diameter of Mercury is $\frac{3}{4}$ of the diameter of the earth, and therefore the globe of Mercury muſt be $\frac{2}{3}$ of that of the earth.

Mr. Azout pretends to prove, that though Mercury be ſo near the ſun, the light there is not capable of burning any objects. But Sir Iſaac Newton makes the heat of Mercury ſo great, as to be ſeven times as much as the heat of our ſummer ſun; which he found, by experiments deſignedly made by the thermometer, is enough to make water boil. And, therefore, if bodies will not be there enkindled by ſuch a degree of heat, it muſt be becauſe their degree of denſity is proportionably greater than that of

of ſuch kinds of bodies on our earth: wherefore, undoubtedly, this fiery planet is uninhabitable by ſuch creatures as live on our earth.

Dr. Halley, in his obſervation of Mercury ſeen in the ſun, in the year 1677, at St. Helena, ſays, that this plant may be ſeen nine times in the ſun, near the aſcending node, in the years 1710, 1723, 1736, 1743, 1756, 1769, 1776, 1782, 1789, in October: and four times near the other node, in the month of April, in the years 1707, 1753, 1786, 1799; all within this century.

Dr. Gregory, in his Elements of Aſtronomy, deſcribes the phænomena that will appear to the eye in Mercury: he ſays, that beſides the phænomena of the order of the fixed ſtars, which agree alike with an eye placed any where within the orbit of Saturn, it is plain that the eye, poſited in Mercury, will ſee the ſun almoſt three times broader than we ſee it from the earth, becauſe that planet is almoſt three times nearer to the ſun than the earth. Whence alſo the ſolar diſk, ſeen from Mercury, is ſeven times greater than the diſk as it appears to us, and Mercury has ſeven times more light and heat, *cæteris paribus*, than the earth. But theſe qualities are much more or leſs intenſe, according to the different diſtance of Mercury from the ſun: for its orbit is much more excentric, than the orbit of any other planet.

The accelerating gravity, towards the ſun, is alſo ſeven times greater there than here.

It has not yet been found by obſervation, whether Mercury turns upon its own axis, and therefore it cannot be certainly defined, whether to an eye, placed on its ſurface, all the things without will appear to revolve with a contrary motion; that is, whether it has the viciſſitude of day and night, much leſs what is the ſpace of its nychthemeron, or natural day: but we may ſafely enough conjecture, that it does revolve about its axis, ſince other planets do. But the year of Mercury is ſcarce equal to a quarter of our year, though it is uncertain whether it has different ſeaſons, becauſe they depend upon the inclination of the axis of its rotation, which is unknown, to the plane of the orbit which it deſcribes about the ſun. The eye placed in Mercury, looking at the ſun, will ſee the ſun's ſpots (when it has any) ſometimes in a right line croſſing his diſk from eaſt to weſt; at another time their way will appear elliptical and curve, towards one ſide or the other; and all the variety of this phænomenon will happen in one year, in which the track or way of the ſpots will appear twice rectilineal. But the way of the ſolar ſpots, ſeen from Mercury, will be always almoſt ſtraight; becauſe Mercury never declines much from the plane of the ſun's equator; and therefore not ſenſibly from the planes of the circles, which the ſpots deſcribe by their rotation. And as the plane of the orbit of the earth is moſt of all inclined to the ſaid plane of the ſun's equator, the way of the ſpots, ſeen from the earth, appears more curve than if the ſun was ſeen from any other planet. This curvature will be ſomething leſs, ſeen from Jupiter or Mars; and yet leſs from Saturn, leſs ſtill from Venus, and leaſt of all from Mercury, as we have juſt obſerved.

The other five planets are ſuperior to Mercury, therefore their phænomena are to an eye placed in Mercury, as the phænomena of Mars, Jupiter and Saturn, ſeen from the earth. Therefore Venus and the earth, when they are in oppoſition with the ſun, will ſhine with a full orb, and reflecting the ſun's rays very directly, will ſhine upon Mercury all night, and powerfully expel the darkneſs. For ſince Venus, when it is horned, and ſhews the leaſt part of its enlightened hemiſphere to the inhabitants of the earth, is ſo bright as to caſt a ſhadow, it will appear very bright to Mercury, to which it turns its whole enlightened hemiſphere.

Mercury ſees no inferior planet known to us, conſequently ſees no celeſtial body falcated or horned; and therefore a ſpectator there, will want the argument taken from ſuch phaſes of the planets, to eſtabliſh the true ſyſtem of the world: for the phaſes of the inferior planets have clearly ſhewn that they move about the ſun; whence it was natural to think the ſame of the other motions. But nevertheleſs, though we do not ſee any planets inferior to Mercury, it does by no means follow that there are no ſuch: for Mercury himſelf is ſeldom ſeen in our oblique ſphere, and one that ſhould be much inferior to it, would never be ſeen upon account of its nearneſs to the ſun.

MERCURY, in heraldry, a term uſed in blazoning by planets, for the purple colour in the arms of ſovereign princes. See BLAZONING.

MERCURY, in matters of literature, denotes a book, or other paper, chiefly filled with news; ſo called from the Pagan deity Mercury, who is ſaid to have been the meſſenger of the gods. Hence alſo the perſon employed to collect news, or diſtribute the news-papers, are called Mercuries.

MERIDIAN, in aſtronomy, a great circle of the ſphere, paſſing through the zenith, nadir, and poles of the world; dividing the ſphere into two hemiſpheres, the eaſtern and weſtern. It is a vertical circle paſſing through the poles of the world.

The word is derived from *meridies*, noon, by reaſon when the ſun is in this circle, it is noon in thoſe places ſituate under it.

To draw a MERIDIAN *Line.*—Knowing the ſouth-quarter pretty nearly, obſerve the altitude F E (plate LXXXVI. *fig.* 2.) of ſome ſtar on the eaſtern ſide thereof, not far from the meridian H Z R N; then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, only directing it to the weſtern ſide of the meridian, wait till the ſtar has the ſame altitude as before, *f e*. Laſtly, biſſect the angle E C *e*, formed by the interſection of the two planes wherein the quadrant is placed at the time of the two obſervations, by the right line H R. This line H R is a meridian line.

Or thus; which is a very eaſy and good method for practice. On an horizontal plane, from the center C, (*fig.* 3.) deſcribe ſeveral concentric arches B A, *b a*, &c. and on the ſame center C, erect a ſtyle or gnomon, perpendicular to the plane A C B, a foot or half a foot long. About the time of the tropics before noon, between the hours of nine and eleven in the morning, and between one and three in the afternoon, obſerve the points B, *b*, &c. A, *a*, wherein the ſhadow of the ſtyle terminates. Biſſect the arches A B, *a b*, &c. in D, *d*, &c. If then the right-line D E biſſect all the arches A B, *a b*, &c. it will be the meridian line ſought. As the extremity of the ſhadow is ſomewhat hard to determine, it will be convenient to have the ſtyle flat at the top, and to drill a little hole, noting the lucid ſpot projected by it, on the arches A B and *a b*, inſtead of the extremity of the ſhadow.

Hence, if the meridian line be biſſected by a right line O V, drawn perpendicularly through the point C, O V will be the interſection of the meridian, and firſt vertical, and conſequently O will ſhew the eaſt point, and V the weſt.

MERIDIAN LINE, on a dial, is a right line ariſing from the interſection of the meridian of the place, with the plane of the dial; this is the line of twelve o'clock, and from hence the diviſion of the hour-lines begins. See DIAL.

Magnetical MERIDIAN, is a great circle paſſing thro' the magnetical poles, to which the magnetic needle, or needle of the mariner's compaſs, conforms itſelf.

MERIDIAN *Altitude of the Sun or Stars*, is their altitude when in the meridian of the place where they are obſerved. Or it may be defined, an arch of a great circle perpendicular to the horizon, and comprehended between the horizon and the ſun or ſtar then in the meridian of the place.

To take the MERIDIAN *Altitude with a Quadrant.*—If the poſition of the meridian be known, and the plane of an aſtronomical quadrant be placed in the meridian line, by means of the plumb-line ſuſpended at the center, the meridian altitudes of the ſtars, which are the principal obſervations whereon the whole art of aſtronomy is founded, may eaſily be determined. The meridian altitude of a ſtar may likewiſe be had by means of a pendulum-clock, if the exact time of the ſtar's paſſage by the meridian be known. Now it muſt be obſerved, that ſtars have the ſame altitude for a minute before and after their paſſage by the meridian, if they be not in or near the zenith; but if they be, their altitudes muſt be taken every minute when they are near the meridian, and their greateſt altitudes

will be the meridian altitudes ſought. See the article QUADRANT.

MERIDIONAL DISTANCE, in navigation, is the ſame with the departure, eaſting or weſting, or the difference of longitude between the meridian under which the ſhip now is, and any other meridian ſhe was before under.

MERIDIONAL PARTS, MILES, or MINUTES, in navigation, are the parts by which the meridians in Mr. Wright's chart, commonly, though falſely, called Mercator's, do increaſe, as the parallels of latitude decreaſe. See *Mercator's* SAILING.

MERIT, in theology, ſignifies deſert. This term is more particularly uſed to ſignify the moral goodneſs of the actions of men, and the rewards to which thoſe actions entitle them.

MERLIN, *Æſalon*, in ornithology, the leaſt of the hawk kind, but much reſembling the haggard-falcon.

MERLON, in fortification, is that part of a parapet which is terminated by two embraſures of a battery. Its height and thickneſs is the ſame with that of the parapet; but its breadth is generally nine feet on the inſide, and ſix on the outſide. It ſerves to cover thoſe on the battery from the enemy; and is better when made of earth well beat and cloſe, than when built with ſtone; becauſe they fly about and wound thoſe they ſhould defend.

MEROPS, the bee-eater, in ornithology, the blue-breaſted iſpida, with a variegated head; a very beautiful bird, ſomewhat larger than the common king-fiſher. See ISPIDA.

MERULA, the blackbird, in ornithology, a ſpecies of the turdus or thruſh-kind. See the article TURDUS.

MESENTERY, in anatomy, a thick fat membrane, placed in the midſt of the inteſtines, particularly of the ſmaller ones, whence it has the name. Its ſubſtance is compoſed of membranes, fat, veſſels of all kinds, and in the human body of a number of glands. In the upper part, it is connected with the three ſuperior vertebræ of the loins; and in the lower, with the inteſtines, and particularly with the jejunum and ileum; to which it alſo gives their outer coat. When it is ſeparated from the inteſtines, it has ſeveral folds reſembling gloves. Its length, in the whole, is about three ells; but the inteſtines which are joined to it, are at leaſt four times that length. Its coats or membranes are two, and between theſe there is a cellular ſubſtance, which contains the fat: meſeraic veſſels and glands are alſo placed there, which many reckon a third coat of the meſentery, and that not improperly; this they call the tunica celluloſa.

MESN, in law, ſignifies him who is lord of a manor, and ſo hath tenants holding of him, yet himſelf holding of a ſuperior lord. This word alſo ſignifies a writ, which lies where there is a lord meſn and tenant, and the tenant is diſtrained for ſervices due from the meſn to the ſuperior lord.

MESOCOLON, in anatomy, that part of the meſentery connected with the great guts, eſpecially the colon.

MESOLABLE, an inſtrument uſed by the ancients for finding two mean proportionals mechanically, which they could not effect geometrically.

It conſiſted of three parallel organs, moving in a groove to certain interſections.

MESOLOGARITHMS, according to Kepler, are the logarithms of the coſines and co-tangents, the former of which were called by lord Napier antilogarithms, and the latter differentials.

They are otherwiſe called artificial ſines and and tangents. See the articles LOGARITHM, SINE, TANGENT, &c.

MESPILUS the medlar, in botany, a genus of plants, the flower of which is made up of roundiſh hollow petals; and its fruit is an umbilicated globoſe berry, containing five oſſeous and gibbous ſeeds.

MESSENGERS are certain officers chiefly employed under the direction of the ſecretaries of ſtate, and always are in readineſs to be ſent with all kinds of diſpatches foreign and domeſtic. They alſo, by virtue of the ſecretaries warrants, take up perſons for high treaſon, or other offences againſt the ſtate.

MESSENGER, a rope faſtened to the cable to draw in, in ſmall ſhips of war.

MESSIAH, the anointed; a title which the Jews gave to their expected great deliverer, whoſe coming they ſtill wait for: and a name the Chriſtians apply to Jeſus Chriſt, in whom the prophecies relating to the Meſſiah were accompliſhed.

Among the Jews, anointing was the ceremony of conſecrating perſons to the higheſt offices and dignities; kings, prieſts, and ſometimes prophets were anointed: thus Aaron and his ſons received the ſacerdotal, Eliſha the prophetic, and David, Solomon, and others, the royal unction.

METAL. See METALLIC *Bodies*.

Prince's METAL, called *Bath* METAL, a kind of factitious metal, of a beautiful yellow, and diſpoſed to receive a fine poliſh, luſtre, &c. It is prepared, according to Dr. Shaw, as follows: take ſix ounces of copper, melting it in a wind furnace; add to it one ounce of zink: then ſtirring the whole well together, pour out the metal immediately. The copper and zink may be put into the crucible together, if firſt covered over with the black flux, which prevents the evolution of the zink, or preſerves its metalline form.

METAL, in heraldry. There are two metals uſed in heraldry, by way of colours, viz. gold and ſilver, in blazonry called *or* and *argent*.

In the common paintings of arms theſe metals are repreſented by white and yellow, which are the natural colours of thoſe metals. In engraving, gold is expreſſed by dotting the coat, &c. all over; and ſilver, by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour upon colour; ſo that if the field be of one of the metals, the bearing muſt be of ſome colour; and if the field be of any colour, the bearing muſt be of one of the metals.

METALLIC *Bodies*, in natural hiſtory, are ſuch metals as are capable of being worked and conſiderably extended under the hammer; and ſemi-metals, or thoſe which want that valuable quality.

There are other characters alſo, no leſs diſcriminative of the two claſſes: metals appear when broke of an uniform, or a fibrous, or a granulated texture; whilſt the broken ſurfaces of ſemi-metals, the fluid one, quickſilver excluded, are compoſed of large angular plates or flakes: metals, expoſed to the moſt intenſe degree of culinary fire, if the air is perfectly ſhut out, remain fixed and unaltered at the botton of the veſſel; whilſt ſemi-metals, impatient of vehement heat, ariſe in fumes into that part of the veſſel which is furtheſt removed from the fire, and there condenſe again into their original form.

Though neither metals or ſemi-metals ſuffer any eſſential change from heat, ſo long as the air is excluded; there are ſeveral bodies of both claſſes, which by the action of fire and air conjointly, are gradually deprived of their metallic appearance and qualities, and converted into a powdery or vitreous ſubſtance, called calx or ſcoria. Hence ariſes a further diſtribution into imperfect, or thoſe which are ſuſceptible of theſe changes; and perfect, or thoſe which ſuffer none.

METALLURGY, *Metallurgia*, according to Boerhaave, comprehends the whole art of preparing and working metals from the glebe, or ore, to the utenſil; in which ſenſe, mineralogy, aſſaying, ſmelting, refining, ſmithery, gilding, &c. are only branches of metallurgy. See MINERALOGY, &c.

Dr. Shaw however reſtrains metallurgy to thoſe operations required to ſeparate metals from their ores, for the uſes of life. Theſe operations are of two kinds, or ſmaller and large; with regard to which the whole art of metallurgy may be divided into two parts, aſſaying and ſmelting. See ASSAYING, &c.

Dr. Cramer obſerves, that the art of aſſaying conſiſts in a well-made ſeparation of minerals, eſpecially metals, and in a diviſion of the ſeveral conſtituent parts of them from each other, in order that the quantity and quality of each in particular may be known: it is plain that thoſe operations

tions which belong to the general clafs of ſolution, appertain ſtrictly and primarily to this; and that the others, which are performed by the aſſayer, are only ſecondary or auxiliary operations. But there is hardly any chemical operation which is not ſometimes neceſſary to be performed in the art of aſſaying: there are many, on the contrary, which are peculiar to aſſaying alone; therefore we have given a general view of thoſe which properly belong to it, or of thoſe which, though taken from chemiſtry at large, are nevertheleſs uſed by aſſayers; only obſerving here that every primary docimaſtical operation may, on account of its effects, be called ſolution, ſince, in every operation, the menſtrua, among which the air and fire have a right to be claſſed, effect a ſolution, by interpoſing themſelves between the parts of the objects to be changed. See the articles MENSTRUUM and FLUX.

Semi-METALS, metallic foſſils, fuſible by fire, and not malleable in their pureſt ſtate. See METALLIC *Bodies*.

METAMORPHOSIS, in general, denotes the changing of ſomething into a different form; in which ſenſe it includes the transformation of inſects, as well as the mythological changes related by the ancient poets.

Mythological metamorphoſes were held to be of two kinds, apparent and real: thus, that of Jupiter into a bull, was only apparent; whereas that of Lycaon into a wolf, was ſuppoſed to be real.

METAPHOR, *Metaphora*, in rhetoric, a figure of ſpeech, whereby the proper denomination of one thing is applied to another, for the greater elegance of expreſſion.

The word is Greek, μεταφορα, and formed of μετα, and φερω, to carry or bring.

A metaphor is a ſimile or compariſon intended to illuſtrate the thing ſpoken of, without the form of compariſon.

If any author is obliged to give a large account of things, plain and of common obſervation, he muſt raiſe and ennoble them by ſtrong and graceful metaphors. This rule Tully has obſerved in his deſcription of the ſeveral parts of this habitable globe, in his book on the Nature of the Gods. So has Virgil, in his Georgics, where he has made his meaneſt and coarſeſt ſubjects fine and admirable, by his judicious uſe of metaphors; in his perfect lines, the little affairs of ſhepherds and farmers appear with dignity; his deſcriptions make the country a paradiſe, and his touches, as a noble writer expreſſes it, turns every thing into gold. Thoſe are admirable and beautiful metaphors, in which the properties of rational creatures are applied to animals, and thoſe of animals to plants and trees; this way of treating a ſubject gives life and beauty to the whole creation. But we receive the ſtrongeſt pleaſure from thoſe bold and comprehenſive metaphors, in which, beſides the illuſtration of the ſubject they are intended to raiſe and improve, convey to us a freſh and lively image.

Metaphors never fail of being beautiful, when applied with nature, judgment, and a lively wit; that is, when they are drawn from nature, and connect ideas that have a due relation to each other, and are not too much wreſted to a foreign ſenſe. But nothing is more abſurd, than when theſe rules are tranſgreſſed, which is very often the caſe with our modern writers.

Cardinal Perron lays down this general rule for metaphors, that they muſt always deſcend from the genus to the ſpecies, and never go backward from the ſpecies to the genus.

Mr. Addiſon propoſes it, as a rule for writers, to imagine their metaphors actually painted before them, and to view and examine the juſtneſs of their application and aſſemblage under theſe circumſtances, throwing every thing out of their writings, but what might be retained in the picture.

METAPHRASE uſually ſignifies ſomething more than either a tranſlation or a paraphraſe: according to Baillet, a metaphraſt implies a tranſlator, gloſſator, and interpolator altogether.

METAPHYSICS, *Metaphyſic*, *Tranſnaturals*, or *Ontology*, a ſcience that treats of being as ſuch in the abſtract, or in general, not reſtrained to this or that ſpecies of it.

The word is Greek, μεταφυσικη, and formed of μετα, beyond or above, and φυσις, nature.

This ſcience is wholly converſant in the acts of the underſtanding, and it raiſes itſelf only to bring about things above the verge of ſenſe and matter, applying itſelf only to beings ſeparated from their individual ſingularity, particularly beings purely ſpiritual. The end of this ſcience is the ſearch of pure and abſtracted truth.

Ariſtotle ſeems to have been the firſt founder of this abſtracted method of reaſoning, and the conſideration of immaterial beings. Indeed, Pythagoras, by his travels into Egypt, learned the unity of the Godhead from the Hebrews, and taught it the Greeks; but he alſo borrowed moſt of the viſions of the Egyptians relative to ſpirits, which they inveſted with ſubtile bodies, and filled the world with their airy train. Plato took the ſame doctrine from Pythagoras, and Zeno afterwards tranſcribed it from Plato.

Antiquity affords nothing on this ſubject compoſed with ſo much ſtrength of reaſon as Cicero's books of the Nature of the Gods. His ſentiments are as juſt, and his doctrine as good, as merely heathen theology could produce.

The chief modern works of this kind are thoſe of Deſcartes, Malebranche, Dr. Willis, Locke, Dr. Moore, &c.

If we are ſhort-ſighted in phyſical matters, which are nearer our ſenſe, and, in a manner, expoſed to our view, how much more muſt we be bewildered in our ſearch after ſpiritual abſtracted truths, in the conſideration of univerſals? This ſcience proceeds in almoſt unknown paths, containing very few doctrines of allowed certainty, few principles in which men are univerſally agreed, ſcarce any juſt definition, any exact diviſion, and, conſequently, affords large matter for doubts and diſputes. Add to this the barbarous terms and perplexed reaſonings with which the ſchools have embarraſſed this ſcience.

We ought by no means to approve of the deſign and notion of ſome contemplative men, who would introduce too great a mixture of metaphyſics into the ſubjects of religion, which ought to be treated with the moſt familiar plainneſs of method.

METAPLASMUS, in grammar, a tranſmutation or change made in a word, by adding, retrenching, or altering a letter, or ſyllables thereof.

METASTASIS, in medicine, a tranſpoſition or ſettlement of ſome humour or diſeaſe, on ſome other part; and ſometimes it ſignifies ſuch an alteration of a diſeaſe, as is ſucceeded by a ſolution.

METATARSUS, in anatomy, a fleſhy maſs lying under the ſole of the foot. See the article FOOT.

METATHESIS, in grammar, a ſpecies of the metaplaſmus; being a figure whereby the letters or ſyllables of a word are tranſpoſed, or ſhifted out of their uſual ſituation, as piſtris for priſtis; Lybia for Libya, &c.

METEMPSYCHOSIS, the doctrine of tranſmigration, which ſuppoſes that human ſouls, upon their leaving the body, become the ſouls of ſuch kind of brutes as they moſt reſemble in their manners.

This was the doctrine of Pythagoras and his followers, who held that the ſouls of vicious men were impriſoned in the bodies of miſerable beaſts, there to do penance for ſeveral ages, at the expiration of which they returned again to animate men; but if they had lived virtuous, ſome happier brute, or even a human creature, was to be their lot.

Pythagoras is ſaid to have borrowed the notion of a metempſychoſis from the Egyptians; others ſay from the ancient Banians, and other idolaters of India and China, and makes the principal foundation of their religion. Many of the modern Jews are ſaid to eſpouſe this doctrine.

METEMPTOSIS, in chronology, denotes the ſolar equation neceſſary to prevent the new moon from happening a day too late.

The word is Greek, and derived from μετα, after, and πιπτω, to fall.

It ſtands contra-diſtinguiſhed from *proemptoſis*, which ſignifies the lunar equation neceſſary to prevent the new moon from appearing a day too ſoon.

The

The new moon's running a little backward, that is, coming a day too ſoon, at the end of three hundred twelve years and a half; by the proemptoſis a day is added every three hundred years, and another every two thouſand four hundred years. On the other hand, by the metemptoſis, a biſſextile is ſuppreſſed every one hundred and thirty-four years; that is, three times in four hundred years. Theſe alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar eaſy.

There are three rules for making this addition or ſuppreſſion of the biſſextile day, and by conſequence for changing the index of the epacts. 1. When there is a metemptoſis without a proemptoſis, the next following, or lower index, muſt be taken. 2. When there is a proemptoſis without a metemptoſis, the next preceding, or ſuperior index is to be taken. 3. When they are both a metemptoſis and proemptoſis, or when there is neither the one nor the other, the ſame index is preſerved.

METEOR, in phyſiology, an imperfect, changeable, and mixt body, or the reſemblance of a body appearing in the atmoſphere, and formed by the action of the heavenly bodies, out of the common elements.

Meteors are of three kinds, fiery, airy, and watery. Fiery meteors conſiſt of a fat ſulphureous ſmoke ſet on fire; ſuch as lightning, thunder, falling ſtars, draco volans, the ignis fatuus, and other phænomena appearing in the air. Airy meteors conſiſt of flatulent and ſpirituous exhalations, ſuch as winds, &c. Watery meteors are compoſed of vapours or watery particles, variouſly modified by heat and cold, ſuch as clouds, rain, hail, ſnow and dew.

METHEGLIN, a ſort of drink prepared from water and honey.

The word is Welſh, *medyglin*, which ſignifies the ſame thing.

The beſt way of making it is as follows; Put as much new honey, naturally running from the comb, into ſpring-water, as that, when the honey is thoroughly diſſolved, an egg will not ſink to the bottom, but be juſt ſuſpended in it. Then boil the liquor for an hour or more, till ſuch time as the egg ſwim above the liquor; then take it off the fire, and let it cool. When very cool, next morning, it may be barrelled up; and adding to it half an ounce of ginger, as much of cloves, as much of mace, and a quarter of an ounce of cinnamon, all groſly pounded, a ſpoonful of yeaſt may be added alſo at the bung to increaſe its fermentation. When it has done working, it may be cloſely ſtopped up, and after it has ſtood a month it may be drawn off into bottles.

METHOD, *methodus*, the art of diſpoſing things in ſuch a manner, as they may be eaſily comprehended, either to diſcover the truth which we ourſelves are ignorant of, or to demonſtrate it to others, when known.

The word is Greek, μεθοδος, and derived from μετα, and οδος, a way.

Gaſſendus divides method, with regard to its object, into the method of invention, or diſcovering a truth unknown, the method of judging of a propoſition propoſed, and the method of demonſtration, or exhibiting it to another.

Method, with regard to the order of procedure, is uſually divided into the method of reſolution, or analytic method, whereby we proceed from ſome general known truth to others which belong to ſome particular thing; and into the method of compoſition, or ſynthetic method, in which we propoſe ſome certain general truths, from which we produce particular truths.

If, in the method of reſolution, we lay down any axioms, it is not immediately in the beginning, but as they are found neceſſary in the diſquiſition; but the caſe is otherwiſe in the method of compoſition.

In both theſe methods, no propoſition ſhould be admitted as true, which is not evident. 2. That the connection of the following propoſition with the foregoing be likewiſe evident in every ſtep.

The laws of the ſynthetic method will be beſt drawn from mathematicians, as, 1. To offer nothing but what is couched in terms perfectly underſtood. 2. To build only on clear principles. 3. To prove demonſtratively all their conſequences, namely, by definitions that have been laid down, axioms that have been granted, and propoſitions that have been already proved; which become principles to things that follow them.

METHOD, in mathematics, more peculiarly denotes certain particular proceſſes for ſolving problems.

METOCHE, in ancient architecture, a term uſed by Vitruvius to ſignify the ſpace or interval between the dentils.

METONIC CYCLE, in chronology, the ſame with the cycle of the moon. See the article CYCLE.

METONYMY, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. By this trope any of the moſt ſignificant circumſtances of a thing are put for the thing itſelf.

METOPE, *Metopa*, in architecture, is the interval, or ſquare ſpace between the triglyphs of the Doric frieze, which among the ancients uſed to be painted or adorned with carved work, repreſenting the heads of oxen, or utenſils uſed in ſacrifices.

Semi-METOPE, in architecture, is a ſpace in the corner of the Doric frieze, ſomewhat leſs than half a metope.

METOPOSCOPY, the pretended art of knowing a perſon's diſpoſitions and manners, by viewing the traces and lines in the face.

METRE, *Meter*, *Metrum*, in poetry, denotes a ſyſtem of feet of a proper length.

The word is derived from the Greek, μετρον, meaſure.

METRETES, an ancient meaſure of capacity, containing a little more than nine gallons.

METRICAL VERSES, thoſe verſes that conſiſt of a determinate number of long and ſhort ſyllables.

METROPOLIS, the capital of a country or province.

The word is Greek, and formed of μητηρ, mother, and πολις, a city, as being the mother or head, as it were, of all the reſt.

It alſo denotes an archiepiſcopal church.

MEUM, ſpignel, in botany, an umbelliferous plant, with buſhy leaves divided into ſlender ſegments, like thoſe of fennel but finer; producing large, oblong, ſtriated ſeeds, flat on one ſide, and convex on the other. The root is long, variouſly branched, with generally a number of hairs or filaments at top, which are the remains of the ſtalks of former years, of a browniſh colour on the outſide, pale or whitiſh within, when dried of a fungous texture. It is perennial, grows wild in meadows in ſome parts of England, and flowers in June.

The root of this plant is recommended as a carminative, ſtomachic, and for attenuating viſcid humours, appearing to be nearly of the ſame nature with that of lovage; differing in its ſmell, being rather more agreeable, ſomewhat like that of parſnips, but ſtronger, and in its taſte being leſs ſweet, and more warm or acrid.

MEW, a place where a hawk is ſet during the time ſhe raiſes her feathers.

MEWING, the falling off, or change of hair, feathers, ſkin, horns, or other parts of animals, which happens in ſome annually, in others only at certain ſtages of their lives; but the generality of beaſts mew in the ſpring.

MEXICO, a large and extenſive kingdom in North-America, divided at preſent into that of Old and New Mexico.

Old MEXICO, ſituated between 83 and 116 degrees of weſt long. and between 8 and 28 deg. north lat. is bounded by New Mexico, or Granada, on the north; by the gulf of Mexico on the north-eaſt; by Terra-Firma on the ſouth-eaſt; and by the Pacific ocean on the ſouth-weſt.

New MEXICO, including California, ſituated between 100 and 140 deg. of weſt long. and between the Tropic of Cancer, and 48 deg. of north lat. is bounded by unknown lands on the north; by Florida on the eaſt; by Old Mexico on the ſouth; and by the Pacific ocean on the weſt.

MEZANINE, or MEZZANINE, a term uſed by ſome architects, to ſignify an entreſole. See the article ENTRESOLE.

The

The word is borrowed from the Italians, who call thoſe little windows which are leſs in height than breadth, that ſerve to illuminate an Attic, mezzanine.

MEZEREON, or MESEREUM, ſpurge-olive, a ſpecies of thymelæa, which agrees in virtue with the ſpurge-laurel. See THYMELÆA.

MEZZOTINTO, a particular manner of repreſenting figures on copper, ſo as to form prints in imitation of painting in Indian ink.

The ſcraping mezzotintos is a kind of engraving, which is executed by covering the ſurface of a copper-plate with lines, ſunk in it cloſe to each other, in different directions; ſo that it would, if uſed for printing in this ſtate, give a black impreſſion, or ground, from the whole: and then taking away or diminiſhing the effect of the ground, by ſcraping or burniſhing, according to the neceſſary expreſſion of any given deſign, ſuch parts of theſe lines as brings the plate to the ſame condition, as if lines had been originally cut, correſpondently to the manner of other engravings, in thoſe places where they were wanted to expreſs the ſhades or darker parts of the deſign.

This appears, therefore, in one view, to be an oppoſite kind of engraving to the others; as in them the ſhades and darker parts are formed by the deſtroying part of the lights, of which the whole ground muſt be conſidered as at firſt conſiſting; whereas in this, the ground being originally all ſhade, the lights are produced by deſtroying the neceſſary parts of thoſe ſhades. As it is much eaſier to ſcrape or burniſh away parts of a dark ground correſpondently with the out-line of any deſign ſketched upon it, than it is to form the ſhades, upon a light ground, by an infinite number of hatches, ſtrokes, and points, which muſt all terminate with exactneſs on the out-line, as well as differ in their force and manner, the method of ſcraping in mezzotinto conſequently becomes much more eaſy and expeditious than any other method of engraving: for which reaſon it is of courſe much better accommodated to painters, or others, who are maſters of deſign, and deſirous to engrave prints, without the long application to attain the talent, and the labour and trouble afterwards required to exerciſe it, that attend the other methods. The forming the ground of the plate, which is part of the neceſſary work, is indeed laborious and tedious: but it may be thrown upon thoſe who are uſed to ſuch mechanical employments; as it requires little ſkill or judgment, unleſs what may be acquired by a ſmall ſhare of practice; being a matter only of care and application; and therefore no proper part of the buſineſs of the artiſt, who is to ſcrape the deſign on the plate. Not only the facility of the work, but the effect of it when finely executed, are great recommendations to this kind of engraving; as the extreme ſoftneſs of the teints, along with a great force of relief, renders the prints, done this way, that are perfect, more generally pleaſing than thoſe engraved in any other manner; which the great number of portraits lately done evinces.

It is, however, only with regard to ſome kind of ſubjects, that this ſpecies of engraving has this merit: portraiture is the great object of its excellence; and ſome landſcapes have been done that are not contemptible: horſes alſo have been attempted with ſucceſs; and ſome deſigns of hiſtory properly adapted may be brought within its reach. But where any thing beſides the portraits of men, and other animals, come in queſtion, there muſt be a peculiar accommodation of the ſubject; as its powers, with reſpect to variety of expreſſion, are much leſs extenſive than thoſe of etching: and conſequently fall far ſhort of thoſe of the graver. The principles, on which the fitneſs or unfitneſs of ſubjects for this kind of engraving are founded, are of two kinds; the one reſpecting the proportion of light and ſhade; the other, the nature of the deſign with regard to the outline. Such pieces as contain large and clear maſſes of light, do not ſucceed at all: but where, on the contrary, there is a large proportion of very dark parts, as in the repreſentations of night ſcenes, or a large proportion of brown ſhades, as in the pictures of Rembrandt, Benedette, and Teniers, in ſome inſtances, the beſt effect is produced, and with the leaſt labour. Such pieces likewiſe, as are of a ſimple compoſition, and do not require great force, and variety of expreſſion, as paſſion and character, are ſuitable; but where great ſpirit and freedom are required to give merit, this manner of engraving fails; as it does not admit of thoſe ſharp and delicate ſtrokes and touches, which are the means of that expreſſion.

Painting MEZZOTINTO *on Glaſs.*—The painting on glaſs by means of mezzotinto prints is performed by cementing the printed ſide of the prints to the ſurface of the glaſs by the aſſiſtance of ſome glutinous body which will not diſſolve in water; and then deſtroying the texture of the paper by water, ſo that it may be rubbed intirely off from the cement upon the glaſs, in the ſame manner as if the original impreſſion had been made there; by which method a complete drawing of the picture deſigned is obtained on the glaſs; and may be coloured by either oil, varniſh, or water colours. The method of performing it is as follows:

Procure a piece of the beſt crown glaſs as near as poſſible in ſize to the print to be taken off; and varniſh it thinly over with turpentine, rendered a little more fluid by the addition of oil of turpentine. Then lay the print on the glaſs, beginning at one end, and preſſing it gently down in every part to the other. In order to prevent any veſicles of air being formed, during the operation of laying it on, by the paper touching the cement unequally in different parts; and to ſettle the whole more cloſely to the glaſs, it will not be improper to paſs a wooden roller of about two inches diameter, well turned, and very ſmooth, over it. This being done, let the glaſs, with the print cemented on it, be gently dried, till the turpentine be perfectly hard: then let the print be thoroughly moiſtened with water; and while it continues wet rub off the paper, by rolling it under the finger, till only a thin film remains. When it is dry, varniſh it over with oil of turpentine, and you may proceed to paint it either with oil, varniſh, or water colours; and the piece, if well executed, will appear on the fore ſide to be elegantly painted on the glaſs.

MIASMA, among phyſicians, denotes ſuch particles as are ſuppoſed to ariſe from diſtempered, putrifying, or poiſonous bodies.

The word is Greek, and derived from μιαινω, to contaminate or defile.

MICHAELMAS, or *Feaſt of St. Michael and all Angels*, a feſtival of the Chriſtian church, obſerved on the 29th of September.

MICROCOSM is chiefly applied to man, who is called the little world, by way of eminence, as being an epitome of all that is wonderful in the great world, or macrocoſm.

The word is Greek, μικροκοσμος, and formed of μικρος, little, and κοσμος, the world.

MICROGRAPHY, *micrographia*, a deſcription of the parts and proportions of objects that are too ſmall to be viewed without the aſſiſtance of a microſcope.

The word is Greek, μικρογραφια, and formed of μικρος, little, and γραφω, to write.

MICROMETER, an aſtronomical machine, which, by means of a ſcrew, meaſures extremely ſmall diſtances in the heavens, &c. to a great degree of accuracy. In ſome micrometers, an inch is divided into 2800 parts, and in others more.

The word is Greek, and derived from μικρος, little, and μετρον, meaſure. Notwithſtanding the invention of the micrometer is aſcribed to M. Huygens, Auzout, and Picard, the two latter having publiſhed one in 1666, yet Mr. Townley, in the Philoſophical Tranſactions, reclaims it for one of our countrymen, Mr. Gaſcoyne. He relates that, from ſome papers of this gentleman's, he learned, that, before our civil wars, he had invented a micrometer, and had made uſe of it for ſome years, in taking the diameter of the planets, diſtances upon land, the moon's diſtance, &c.

The micrometer conſiſts of a graduated circle, (plate LXXXVI. *fig.* 4.) of a ſcrew *q o*, and its index *q r*. The threads of the ſcrew are ſuch, that 50 make the length of one inch exactly. When it is to be uſed, the point *o* is ſet to the ſide of the part to be meaſured, and then the index is turned about with the finger, till the eye perceives the point has juſt paſſed over the diameter of the part; then the number of turns, and parts of a turn, ſhewn by the graduated circle, will give the dimenſions

in part of an inch, as we ſhall ſhew by the following example: Suppoſe it required to meaſure the diameter of an human hair, and I obſerve the index is turned juſt once round, while the point *o* paſſes over it. Then it is plain the diameter of the hair in the image is $\frac{1}{50}$ of an inch. Now if the microſcope, I D E F *def*, magnifies 6 times, or makes the image 6 times larger in diameter than the object, then is the diameter of the hair itſelf but $\frac{1}{6}$ of $\frac{1}{50}$, that is, but $\frac{1}{300}$ part of an inch.

Alſo it is to be obſerved, that as there are 10 large diviſions, and 20 ſmall ones, on the micrometer-plate; ſo each of thoſe ſmall diviſions are the $\frac{1}{20}$ of $\frac{1}{50}$, or the $\frac{1}{1000}$ part of an inch. Therefore, if, in meaſuring any part of an object, you obſerve how many of theſe ſmaller diviſions are paſſed over by the index, you will have ſo many thouſandth parts of an inch for the meaſure required. All which is ſo plain, that nothing can be ſaid to illuſtrate the matter.

MICROSCOPE, an optical inſtrument, whereby very minute objects are repreſented extremely large and diſtinct, according to the laws of refraction.

The word is Greek, and compounded of *μικρος*, ſmall, and *σκοπεω*, to view.

Microſcopes are of two kinds, ſimple and compound. The firſt ſort conſiſts of one glaſs; the other of two or more. The ſimple microſcope is no other than a convex lens, through which objects appear magnified.

An object ſeen through this microſcope appears magnified nearly in that proportion which the diſtance, at which an object would be ſeen diſtinctly with the naked eye, bears to the focal diſtance of the microſcope. Thus, let A B (plate LXXXVI. *fig.* 5) repreſent the microſcope, C D an object placed at the focal diſtance of parallel rays, or ſomething nearer, that the rays of the ſame pencil may be parallel to each other, or rather diverging in a ſmall degree, when they enter the eye, this circumſtance being requiſite to diſtinct viſion; and let the microſcope be ſo ſmall, that all the rays that paſs through it from the object may enter the pupil of the eye E F at the ſame time, when placed cloſe to it, as in the figure; for unleſs it be ſo ſmall, it will ſcarce magnify ſufficiently to obtain the name of microſcope. Things being thus expoſed, the angle under which this object appears will be G I H, or C I D; but this is nearly the ſame it would have appeared under, had there been no microſcope interpoſed: notwithſtanding which, the object is properly enough ſaid to appear magnified by this microſcope, becauſe, without that, it could not have been ſeen diſtinctly at ſo ſmall a diſtance from the eye, but muſt have been ſituated eight or ten inches from it; and therefore, ſince objects appear under a larger angle, the nearer they are to the naked eye, this object appears larger, or is magnified by means of the microſcope, in proportion as it is ſeen diſtinctly at a leſs diſtance with it than without it; that is, nearly as the focal diſtance of the microſcope is to that at which objects are ſeen diſtinctly with the naked eye.

An object will alſo appear diſtinct, though it be ſituated at a very ſmall diſtance from the eye, by being viewed through a ſmall hole in a piece of paper; but then this hole muſt be made ſo very ſmall, that, unleſs the object be ſtrongly illuminated, it will appear very obſcurely through it.

The form of a compound microſcope is expreſſed in *fig.* 6. where A B repreſents a ſmall convex lens, whoſe focal diſtance is ſuch, that rays flowing from the point C may be collected in D; and E F is a large lens, whoſe focus of parallel rays coincides with the point D; and F G repreſents an eye ſo ſituated, that rays proceeding from an object at K L may enter the pupil of it, after having paſſed through both glaſſes. Theſe things being diſpoſed in this manner, the object K L will appear magnified, and alſo diſtinct.

For, firſt, let R C S repreſent a pencil of rays flowing from the point C, theſe will meet their axis again in the point D by ſuppoſition, and, croſſing there, will enter the lens E F diverging from its focus of parallel rays, and will therefore enter the pupil of the eye in directions parallel to each other, and concur upon the retina at Q; the object will therefore appear diſtinct.

Secondly, a pencil of rays flowing from another point of the object, as L, will meet their axis in M, and, diverging from thence, will, after being refracted by the lens E F, become parallel with reſpect to each other; but, with reſpect to the former, they will converge; becauſe, with regard to them, they diverged before they paſſed through the lens E F from I, a point farther diſtant than its focus of parallel rays. They will therefore, conſequently, croſs them at ſome diſtance from it, ſuppoſe at H, where the pupil of an eye being placed to receive them, the point L will be repreſented at O. And for the ſame reaſon, the point K being repreſented at P, the object will be ſeen under the angle P H O, or E H F, which is much larger than that under which it would have appeared to the naked eye. It may be remarked here, that when we view an object through an inſtrument of this kind, we are then in reality looking at the image of that object through a ſingle microſcope. Thus M N is the image of the object we ſee through the lens or ſingle microſcope E F; ſo that the addition of the glaſs A B is only that we may have an image of the object to look at, larger than the object itſelf.

The glaſs ſituated next the object, is called the object-glaſs; and that placed next the eye, the eye-glaſs.

In ſome microſcopes there is a third glaſs placed between the object glaſs and the image, and is called a middle glaſs. This is placed there only to bring the rays to a focus the ſooner, in order that the image may fall nearer the object-glaſs than it otherwiſe would do.

The proportion of magnifying in a microſcope of this kind, is nearly in a ratio compounded of the proportion which the diſtance of the image from the object-glaſs, bears to its diſtance from the eye glaſs, and of that which the diſtance of the object from the eye bears to its diſtance from the object-glaſs.

Catadioptric MICROSCOPE, is that which performs its effects by reflection and refraction conjointly; for it is conſtructed with a ſmall ſpeculum f e d (plate LXXXVI. *fig.* 7.) whoſe focus is at *f*; and it is plain, that if a ſmall object a b be placed a little further from the ſpeculum than the focus *f*, there will be formed a large image of it A B; which image will be inverted, and in proportion to the object, as the diſtance C e to the diſtance *f*e, as when an object lens was uſed.

Part of this image is viewed by the eye-glaſs F D, which muſt be a meniſcus; becauſe the image being formed by reflection, it will be more perfect, and admit of a greater charge in the eye-glaſs; and thoſe of the meniſcus form are beſt for this purpoſe, becauſe the errors of the rays, and conſequently the confuſion cauſed thereby, in the refraction made at the convex ſurface, are, in a great meaſure, rectified by the contrary refraction at the concave ſurface.

Another ſort of catoptric or reflection microſcope is conſtructed with two ſpeculums a b c d and A B C D (*fig.* 9.) with a central hole in each. The larger ſpeculum is concave, the other convex, and both of equal ſphericity. They have their focus at one inch diſtance, and placed one inch and a half from each other, ſo that an object O P Q, being placed a little before the ſmaller ſpeculum, might be nearer the larger one than its center E.

This being the caſe, the rays P A, P D, which flow from the point P, to the ſpeculum A D, will be reflected towards a focus *p*, where an image *o p q* would be formed, if the rays were not intercepted by the convex ſpeculum a b; and the point *p* being nearer its focus f, the rays A a, D d, which tend towards it, will be reflected to a focus *P*, where the laſt image *O P Q* will be formed, to be viewed by the eye-glaſs G, tranſmitting parallel rays to the eye at I.

But the following is a much better method of conſtructing a catoptric microſcope, with two reflecting mirrors. A B C D E F (*fig.* 8) is a caſe or tube, in one end of which is placed a concave ſpeculum G H, with a hole I K, in the middle; the center of this ſpeculum is at c, and its focus at O; ſo that V O = O c. At the open end of the tube is placed a ſmall convex ſpeculum d e f on a foot e F, by which it is moveable nearer to, or farther from, the larger ſpeculum G H, as occaſion requires.

If now the object a b be poſited in the center *c* of the larger ſpeculum, the image thereof *a b* will be formed in th

that place; and this conſideration is all the reaſon of this form of a microſcope; for if we now look upon the image *a b*, as an object nearer to the convex ſpeculum d *f*, than its focus *f*, it is plain a larger image *AB* will be formed thereby at the focus *C*; or that the rays c G, c H, proceeding from any point c in the object a b, will be reflected back upon themſelves, as being perpendicular to the ſpeculum; but the reflected rays meeting with, or impinging on, the convex ſurface of the ſpeculum d f, will, as they tend to a point *e*, nearer than the focus f, be reflected to a focus *C*, and be ſeen more clearly. Q is a concave looking-glaſs, which reflects the light of a candle, or the ſky, directly upwards on the object to be viewed. V is a plano-convex lens, which ſerves to tranſmit the light of a candle or ſun-ſhine upon any opake object which is placed on the ivory or ebony for examination.

The ſolar or camera obſcura MICROSCOPE depends on the ſun-ſhine, and muſt be made uſe of in a darkened chamber, as its name implies. This inſtrument conſiſts of ſeveral parts, viz. A (plate LXXXVII. *fig.* 2.) a ſquare frame of mahogany to be fixed to the ſhutter of a window, by means of the ſcrews 1, 1. To this frame is applied a circular collar of the ſame wood, with a groove on its periphery on the outſide, denoted by 2, 3. This collar is connected by a cat-gut to the pully 4 on the upper-part, which is turned round by the pin 9 within. On one part of the collar, on the outſide, is faſtened, by hinges, a looking glaſs G, in a proper frame, to which is fixed the jointed wire 6, 7; by which means, and the ſcrew H 8, it may be made to ſtand in an angle more or leſs inclined to the frame. In the middle of the collar is fixed a tube of braſs C, near two inches in diameter; the end of which, on the outſide, has a convex lens 5 to collect the ſun beams thrown on it by the glaſs G, and converging them towards a focus in the other part, where D is a tube ſliding in and out to adjuſt the object to a due diſtance from the focus. To the end G of another tube F, is ſcrewed one of Wilſon's ſingle pocket-microſcopes, containing the object to be magnified in a ſlider; and by the tube F, ſliding on the ſmall end E of the tube D, it is brought to a due focal diſtance.

The ſun's rays being directed by the looking-glaſs through the tube upon the object, the image or picture of the object is thrown diſtinctly and beautifully upon a ſcreen of white paper, or a white linnen ſheet, placed at ſome diſtance to receive the ſame; and may be magnified to a ſize beyond the imagination of thoſe who have not ſeen it. For the farther off the ſcreen is removed, the larger will the object appear, inſomuch that a louſe may be magnified to the length of five or ſix feet, or even a great deal more; but it is more diſtinct when not enlarged to above half that ſize.

This inſtrument has been contrived very commodiouſly in ſeveral different forms; but we ſhall here illuſtrate the following by a diagram. A R (*fig.* 3.) is a ſection of the window-ſhutter of a dark room, C D of the frame containing a ſcioptric ball E F; in the forepart whereof is ſcrewed the tube G I K H, at one end of which is a lens G H, which, by converging the ſun-beams into a narrow compaſs, does ſtrongly enlighten the ſmall object *a b*, placed on a ſlip of glaſs, or otherwiſe, in the part of the tube N Q, where a ſlit is made on each ſide for that purpoſe. Within this tube there ſlides another, L *m r* M, which contains a ſmall magnifying lens *m r*. By moving the exterior tube, I G H K, one way and the other, the glaſs G H will be brought to receive the rays of the ſun directly, and will therefore moſt intenſely illuminate the object *a b*. The other tube, L M, being ſlid backwards and forwards, will adjuſt the diſtance of the ſmaller lens *m r*, ſo that the image of the object *a b* ſhall be made very diſtinct, on the oppoſite ſide of the room at O P; and the magnitude of the image will be to that of the object, as its diſtance from the lens *m r* is to the diſtance of the object from it, as is evident from the figure.

Thus, for example, ſuppoſe the focal diſtance of the lens *m r* to be one inch $= r$, and let the diſtance at which it is placed from the object be 1, $1 = d$; then, if the lens be double and equally convex, as uſual, the diſtance of the image will be $\frac{dr}{d-r} = f = 110$; therefore the image will be 110 times larger than the object in its linear dimenſions, and $110 \times 110 = 12100$ times larger in ſurface; and in ſolidity it will be $110 \times 110 \times 110 = 1333100$ times larger than the object.

This is the moſt entertaining of any; and, perhaps, the moſt capable of making diſcoveries in objects that are not too opake, as it ſhews them much larger than can be done any other way. Such too as have no ſkill in drawing, may, by this contrivance, eaſily ſketch out the exact figure of any object they have a mind to preſerve a picture of.

MID-HEAVEN, the point of the ecliptic that culminates, or in which it cuts the meridian.

MIDSHIP-BEAM, in naval architecture, that which is ſituated in the middle of the ſhip, which forms her extreme breadth, and from which the proportion of the maſts and yards are taken. See BEAM.

MIDSHIP-FRAME. A frame of timbers is compoſed of one floor-timber, two or three futtocks, and a top-timber on each ſide; all theſe being united together, and ſecured by croſs-bars, form a circular encloſure: that which incloſes the greateſt ſpace is called the midſhip-frame. The curve of this frame is inverted at the lower-part, ſo that the floor-timber will be ſomewhat hollow in the middle, whereby the ends will form a very obtuſe angle; but this angle decreaſes the farther the frames are removed from the midſhips, in ſuch a manner that the foremoſt and aftermoſt will become very ſharp, and form a very acute angle. Theſe ſort of floor-timbers are called crotches. See the articles CROTCHES, SHIP-BUILDING, and TIMBER.

The timbers of a ſhip are as the ribs to the human body; and ſerve to ſupport the ſides, the planks thereof being all faſtened to them.

The midſhip-frame is always at the broadeſt part of the ſhip. Builders differ about the form of this frame; but there are ſeveral preliminary operations which are neceſſary to be obſerved, in all the different methods uſed in forming it, and great care ought to be taken therein, becauſe the form of all the other timbers chiefly depends upon it, but not altogether; for two ſhips may be ſimilar as to their midſhip-frames, and yet very different afore and abaft; and though the artiſts ſhould make themſelves acquainted with all the different ways of forming this frame, we ſhould recommend that method to them which is the ſimpleſt, and which gives them the moſt liberty to vary the form of it, according to every one's particular taſte or fancy; and it is very poſſible there may be ſeveral other methods as eaſy and plain as thoſe we have deſcribed. This frame being once formed, we may form all the reſt upon the ſame plane. *Murray's Abridgment of Du Hamel's Elements of Naval Architecture.*

MIDSHIP-MAN, in the royal navy, a young officer, who walks on the quarter-deck, and gangways of a ſhip, and forwards the commands of the ſuperior officers. They are generally voluntiers like the cadets in the army, and ſerve in expectation of a commiſſion. They muſt however ſerve ſix years at ſea before they can be qualified to receive it.

MIDSHIPS, the middle of the ſhip. See the article A-MIDSHIPS.

MILE, *Mille Paſſus*, a meaſure of length or diſtance, containing eight furlongs, &c.

We ſhall here give a table of the miles in uſe among the principal nations of Europe, in geometrical paces, 60,000 of which make a degree of the equator.

	Geometrical paces.
Mile of Ruſſia	750
—— of Italy	1000
—— of England	1200
—— of Scotland and Ireland	1500
Old league of France	1500
The ſmall league of France	2000
The mean league of France	2500
The great league of France	3000
Mile of Poland	3000
—— of Spain	3428
—— of Germany	4000
—— of Sweden	5000
—— of Denmark	5000
—— of Hungary	6000

MILIARY, in general, ſomething reſembling millet-ſeeds.

MILIARY-FEVER. See the article FEVER.

MILITANT, or CHURCH-MILITANT, denotes the body of Chriſtians while here on earth.

MILITARY, ſomething belonging to the ſoldiery or militia.

MILITARY ARCHITECTURE, the ſame with fortification. See FORTIFICATION.

MILITARY ART, the ſcience or art of making or ſuſtaining war to advantage.

MILITARY COLUMN, among the Romans. See COLUMN.

MILITARY WAYS, *Viæ Militares*, the large Roman roads which Agrippa procured to be made through the empire in Auguſtus's time, for the marching of troops and conveying of carriages. Theſe were paved from the gates of Rome, to the utmoſt limits of the empire. See ROAD.

MILITIA, in general, denotes the body of ſoldiers, or thoſe who make profeſſion of arms.

In a more reſtrained ſenſe, militia denotes the trained bands of a town or county, who arm themſelves, upon a ſhort warning, for their own defence. So that, in this ſenſe, militia is oppoſed to regular or ſtated troops.

For the direction and command of the militia, the king conſtitutes lords-lieutenants of each county.

MILK, *Lac*, a white juice which nature prepares in the breaſts of women, and the udders of other animals, for the nouriſhment of their young.

It is derived from the pure chyle, conveyed by the arteries to the breaſts, and without any other coction filtered through the glands of which they conſiſt, without undergoing any conſiderable change.

Milk is a compoſition of three different parts, butyrous, caſeous, and ſerous: the butyrous parts are the cream and oil that ſwim a-top; the caſeous are the groſſer parts, and thoſe that coagulate are made into cheeſe: the ſerous are properly a lymph, and make whey.

By their own milk, all the known lactiferous animals are nouriſhed, both male and female; and from this alone every ſuch animal prepares all the other parts, both the ſolid and fluid, by means of the vital actions. It is alſo certain that men may live for years upon milk alone, and perform all the actions of life, and have all the ſolid and fluid parts of their bodies perfectly elaborated.

The human milk is very ſweet and thin; the next is that of aſſes, then that of mares, then that of goats, and laſtly of cows; whence it is preſcribed in this order to conſumptive perſons of weak viſcera.

Dr. Cheyne extols a milk diet in his writings, particularly his method of cure in diſeaſes of body and mind, his eſſays on the gout, health, and long life, &c.

The beſt of all other milks is human milk, ſince it is moſt adapted to our natures; for which reaſon it is always to be preferred to the milk of other animals. It ought to be furniſhed by a ſound woman, who uſes due exercife, obſerves a laudable regimen, and is in the prime of her age. It is alſo beſt when the breaſts are drawn four or five hours after eating; for then the chyle is changed into concocted milk, and begins to aſſume the nature of the human fluids.

MILL, a machine or engine for grinding corn, &c. of which there are ſeveral kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horſes, &c.

In water-mills the momentum of the water is the moving power, and the attrition of the two ſtones in grinding, is the force to be overcome. Of theſe there are two kinds, viz. thoſe where the force of the water is applied above the wheel, and thoſe where it is applied below the wheel, the former being called over-ſhot, and the latter under-ſhot mills; and to theſe we may add a breaſt-mill, where the water ſtrikes againſt the middle of the wheel.

Some may imagine, that it is hardly worth while to write about ſo common a thing as a corn-mill; but the commonneſs of it ſhews its uſefulneſs, and therefore it would be unpardonable in us to paſs it over in ſilence.

Few people are ignorant, that corn is ground by two mill-ſtones, placed one above the other, without touching. The lower or neither mill-ſtone is immoveable, but the upper one turns upon a ſpindle. The oppoſite ſurfaces of the two ſtones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one ſwells up; each of them being of a conic figure, whoſe axis indeed is very ſhort in proportion to the diameter of its baſe; for the upper one, being ſix feet in diameter, is hollowed, but about one inch at its center; and the lower one riſes but about $\frac{1}{4}$ of an inch. Theſe two mill-ſtones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to inſinuate between them as far as $\frac{2}{3}$ of the radius, which is the place where it begins to be ground, and where it makes the greateſt reſiſtance that it is capable of; the ſpace between the ſtones being in that place but about $\frac{1}{3}$ or $\frac{1}{4}$ of the thickneſs of a grain of corn. But as the millers have the liberty of raiſing or ſinking the upper ſtone a little, they can proportion its diſtance from the lower one, according as they would have the flour finer or coarſer.

The circular motion of the upper mill-ſtone brings the corn out of the hopper by jerks, and cauſes it to recede from the center towards the circumference, where being quite reduced to flour, it is thrown out of the mill, by the centrifugal force of the ſtone, through a hole provided on purpoſe.

As the water acts upon an over-ſhot mill both by impulſe and weight, ſo does it likewiſe upon a breaſt-mill, or that where the water comes upon the breaſt, or middle part of the wheel. And here, though the weight of the water is not ſo great as in the over-ſhot mill, being contained in the buckets of the lower quarter only; yet the impulſe of the water is much greater, the height of the water being increaſed nearly the ſemi diameter of the great wheel, all other things being equal. If the height of the water remain the ſame, the aperture of the penſtock muſt be enlarged to nearly twice the area, that the force may be the ſame; ſo that to produce the ſame effect, twice as much water is neceſſary for a breaſt mill as for an over-ſhot one, every thing elſe being the ſame.

As to the under-ſhot mill, it is evident there can be only the impulſe from the water; and therefore, the height of the water remaining the ſame, there muſt be a larger aperture of the penſtock for the diſcharge of a greater quantity of water in the ſame time, in order to produce the ſame effect as in the over-ſhot or breaſt-mill: whence a greater expence of water will be made here than in any other mill, and can only be ſupplied for a conſtancy by a river; and where this can be had, the under-ſhot is the eaſieſt, cheapeſt, and moſt ſimple ſtructure a mill is capable of.

The diameter of common mill-ſtones, according to Dr. Deſaguliers, is from five to ſeven feet, and their thickneſs, twelve, fifteen, or eighteen inches: they laſt thirty-five or forty years; and when they have been long uſed, ſo that their thickneſs is conſiderably diminiſhed, they are cut anew.

The following is a deſcription of an underſhot-mill, taken from Belidor's Architecture Hydraulique. AB (plate LXXXVII. *fig.* 4.) is the underſhot-wheel, upon whoſe ſhaft D is fixed a ſpur or cog-wheel E, whoſe cogs take the rounds of the trundle or lantern G, which carries round the mill-ſtone in the hurſt or round frame I, containing the lower mill-ſtone at NN, and the upper one at VV; the axis, or ſpindle, fixed to the upper mill-ſtone being the iron-bar FH. They commonly make theſe ſort of underſhot-wheels from twelve to eighteen feet in diameter, the float-boards about two and a half or three feet long, and ten or twelve inches deep. The ſhaft is fifteen or eighteen inches in diameter; the cog-wheel, eight feet in diameter: it has forty-eight cogs four inches high, and three inches and a half wide. The lantern or trundle is made of two round pieces, or flat heads, twenty-two inches in diameter, and four inches thick, in which are ſet nine rounds of two inches and a half diameter, and eighteen inches high. Through the trundle goes an iron axis, two inches and a half ſquare, and of a height proportionable to the ſituation of the mill-ſtones: it muſt be well faſtened to the upper mill-ſtone, and its lower end being reduced to a pivot, turns in a ſocket let

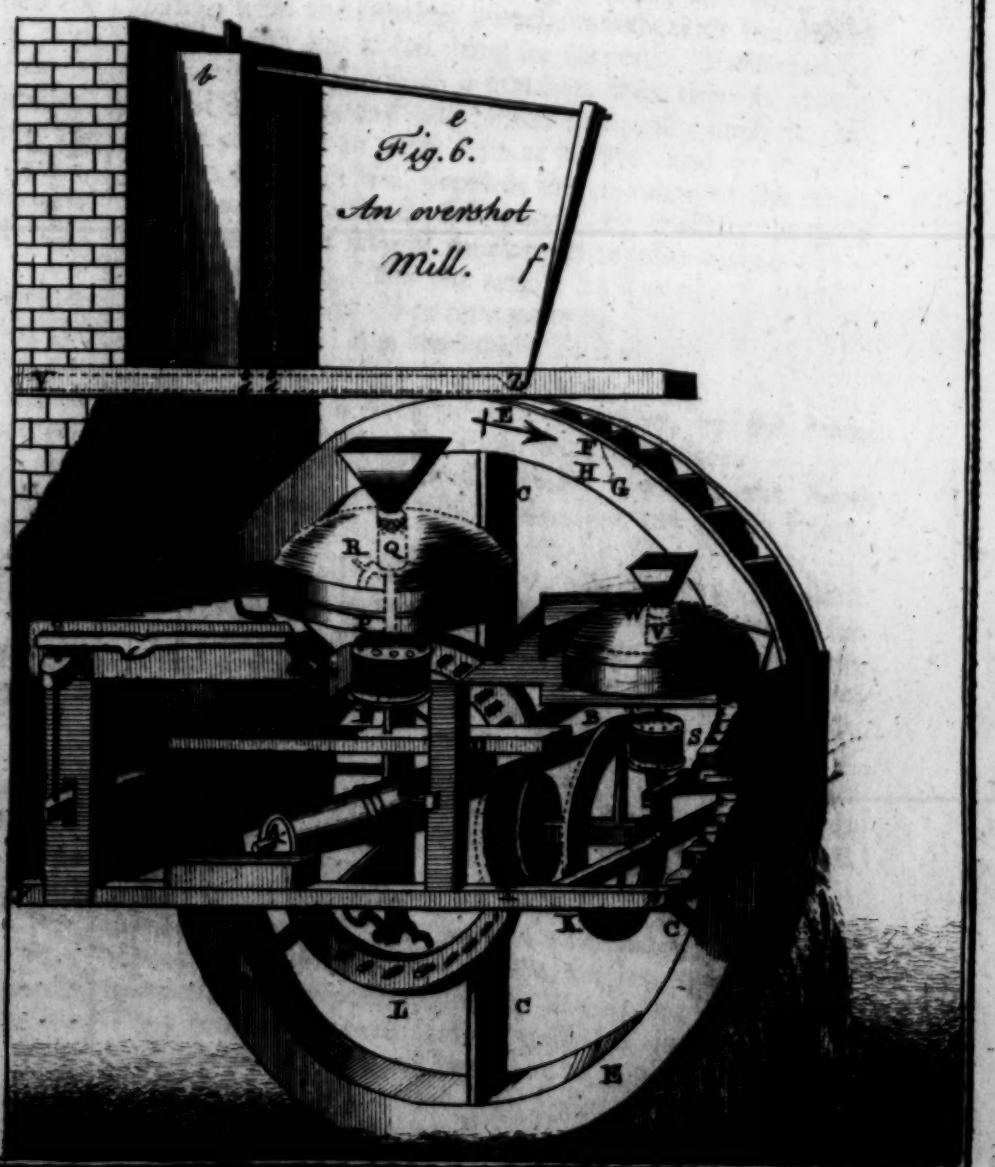

Fig. 7.
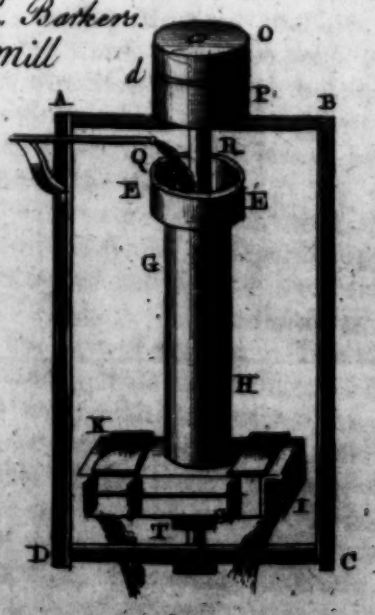
Dr. Barkers. mill



5 JA 59

let into the ſupporting piece H. The ſection of a mill-hopper and drum that covers the mill-ſtones, is repreſented in *fig.* 5. The hopper is a ſmall trough A, with a ſpout B, to convey the corn out of the hopper into the aperture of the upper mill-ſtone, DD. The iron-bar which paſſes through the trundle, is marked C, and the under mill-ſtone EE, the interval or ſpace between the ſtones being repreſented by the dark crooked line FF.

To this account of an underſhot-mill, we ſhall add that of an overſhot one; wherein AB (*fig.* 6.) is the axle tree or ſhaft of the water-wheel, which has ſix arms C, C, &c. fixed in it at D. The ſole of the wheel, marked EEE, is fixed, and contains thirty buckets, about eighteen inches broad, and fourteen inches deep; the elbow to the ſole, GH, being four inches. L, a cog-wheel placed on the ſame ſhaft by four arms at M, has forty-eight cogs, which turn the wallower, pinion, or trundle N, with nine rounds or leaves; and in this trundle is fixed an iron-ſpindle NQ, going through the middle of the lower mill-ſtone P, and turning the upper one R, by means of the rind Q.

I is another wallower or trundle, which is applied at pleaſure to the cog-wheel L; and on the ſame axis is another cog-wheel K, having forty cogs, which turn S, a wallower of nine rounds; whoſe axis T has a rind V at its top, whereby it bears and turns the upper mill-ſtone W. YZ is a trough or lander, which conveys the water from the pool or dam to the buckets of the wheel at Z. This has a penſtock *ab*, and an orifice *cd*, with a ſhuttle or ſluice to open or ſhut it; and is generally raiſed about two inches above the wheel, by means of a lever *e*, fixed to the ſhank by the handle *f*. The ſurface of the water in the pool muſt be conſiderably higher than the level of the top of the wheel.

Dr. Barker's new invented mill (*fig.* 7.) is of the moſt ſimple ſtructure of any yet made, performing its effect without any wheel, trundle, cog, or round; the manner of whoſe operation may be eaſily underſtood from the following account of its ſeveral parts. ABCD is an upright frame, ſtanding on a proper baſe; EF is the wider part of GH, an upright hollow pipe or tube, fixed at the bottom to an horizontal ſquare trunk IK; which trunk, together with the tube, is fixed to an upright ſpindle or axis RS, by means of a nut and ſcrew at S. The lower end of the axis moves on a fine point in the pivot-hole, in the part of the frame at T. On the upper part of the frame is a hole through which the ſpindle paſſes, as alſo through the round circular piece P, fixed on the ſaid frame. On the upper part of the ſpindle is fixed another round piece O, which repreſents the upper mill-ſtone. Q is a ſpout of water filling the tube or trunk, and giving motion thereto; and conſequently to the axis and upper ſtone, by the horizontal jets of water from each end to the trunk IK, through holes made at each end on contrary ſides.

While the holes continue ſtopped, the trunk will be at reſt, becauſe then the preſſure is equal over all the parts; but when the holes are open, the preſſure of the water (by its having liberty to iſſue out) will be leſs on that part where the hole is, than on the other part oppoſite to it; which ſtronger preſſure will prevail, and carry round the trunk and tube with the axle and ſtone, in a contrary direction; and each hole contributes to produce this motion, which will be greater or leſſer in proportion to the momenta of the jets of water, or greater or leſſer aperture of the holes.

For it is eaſy to underſtand, that the power of this machine is derived from, or depends upon, three things: 1. The velocity of the ſpouting-water. 2. The quantity thereof. And, 3. The diſtance at which the water ſpouts from the axis of motion. The two firſt make the momentum ariſing from the preſſure of the fluid, which is proportional to the altitude or height of the tube; the laſt is of a mechanical nature, for the trunk is, in this reſpect, exactly of the nature of the lever.

When the quantity of water is not ſufficient to turn an underſhot wheel, and there is not height enough for an over-ſhot one, the water is made to fall into the buckets of a breaſt-wheel, as it is called (ſee plate LXXXVIII. *fig.* 1.) about the height of the center of the ſhaft, and to work by its weight till it gets to the bottom.

MILL is alſo uſed for any machine, which being moved by ſome external force, makes a ſtrong impreſſion on things applied thereto; ſuch are fulling-mills, paper-mills, mills uſed in coining, gunpowder-mills, oil-mills, ſtamping-mills, ſugar-mills, &c. See FULLING, PAPER, COINING, &c.

Cyder-MILL. See the article CYDER.

Gun-powder-MILL is that uſed for pounding and beating together the ingredients of which gun-powder is compoſed. See the article GUN-POWDER.

Theſe ingredients being duly proportioned, and put into the mortars of the mills, which are hollow pieces of wood, each capable of holding twenty pounds of paſte, are incorporated by means of the peſtle and ſpindle. There are twenty-four mortars in each mill, where are made each day 480 pounds of gun-powder; care being taken to ſprinkle the ingredients in the mortars with water, from time to time, leſt they ſhould take fire. The peſtle is a piece of wood ten feet high, and 4½ inches broad, armed at bottom with a round piece of metal. It weighs about ſixty pounds.

But the operation of this mill will be better conceived from an inſpection of its ſeveral parts. Plate LXXXVIII. *fig.* 2. repreſents the plan of the water-wheel and trundle-heads; where A is the wheel; B its arbor; C, D, the two trundle-heads, each turning with their proper arbor; E, the cog-wheel, driven by the arbors of the great wheel, and inſerting its teeth between the ſpindles of the trundle-heads, makes one of them turn one way, and the other another way.

Fig. 3. is the profile of the great wheel and cog-wheel, marked A and E; where BB is the arbor of the great wheel, C the arbor of the trundle-head C, FF the peſtles, and HH the outſides of the mortars.

Fig. 4. is a plan of the whole machine; A being the great wheel, B its arbor, C, D, the trundle-heads, each with its proper arbor, called here canting-wheel; being each environed with twelve ſmall pieces of wood, called lifts, jutting out to raiſe the peſtles. E is the cog-wheel, GG the tails of the peſtles, and HH the bottoms of the mortars.

If water be given to the great wheel, the cog-wheel muſt likewiſe move and drive contrary ways the two trundle-heads and their canting-wheels; and each lift, turning with the canting-wheels, meets with the ſtay of a peſtle, and lets it fall into its mortar. Theſe twelve lifts are diſpoſed in ſuch a manner, that there is always four of them up, and four peſtles unequally ready to fall, ſo that only one of them falls at a time; and on this diſpoſition of the peſtles depends the equality of the trituration, which ſucceeds ſtill better, by making the paſte paſs through the ſeveral mortars at regular times.

Sawing-MILL. See the article SAWING.

Stamping-MILL. See STAMPING.

Sugar-MILL. See the article SUGAR.

MILL-DEW, *rubigo*. See RUBIGO.

MILL-POOL, a ſtock or pond of water, by the force of which the motion of a water-mill is effected.

The dam of a mill-pool is raiſed much in the ſame manner as directed for fiſh-ponds. See the article FISH-POND.

MILLEFOLIUM, yarrow, in botany, a plant with rough ſtiff leaves, divided into ſmall ſegments, ſet in pairs along a middle rib like feathers: the little flowers ſtand thick together, in form of an umbel on the top of the ſtiff ſtalk, and conſiſt each of ſeveral whitiſh or pale purpliſh petala, ſet round a kind of looſe diſk of the ſame colour, followed by ſmall crooked ſeeds. It is perennial, grows plentifully by the ſides of fields and on ſandy commons, and is found in flower greateſt part of the ſummer.

The leaves and flowers of milfoil are greatly recommended by ſome of the German phyſicians, as mild corroborants, traumatics, and antiſpaſmodics, in diarrhœas, hemorrhages, hypochondriacal, and other diſtempers. They promiſe by their ſenſible qualities, to be of no inconſiderable activity. They have an agreeable, though weak, aromatic ſmell, and a bitteriſh, rough, ſomewhat

pungent taſte. The leaves are chiefly directed for medicinal uſe, as having the greateſt bitterneſs and auſterity: the flowers have the ſtrongeſt and moſt ſubtile ſmell, and promiſe to be of moſt efficacy, if the plant has really any ſuch efficacy, as an anodyne or antiſpaſmodic. Dr. Grew obſerves, that the young roots have a glowing warm taſte, approaching to that of contrayerva, and thinks they might in ſome meaſure ſupply its place; but adds, that they loſe much of their virtue in being dried, from whence it may be preſumed that their active matter is of another kind.

MILLENARIANS, or CHILIASTS, a name given to thoſe, who, in the primitive ages, believed that the ſaints will one day reign on earth with Chriſt a thouſand years. The former appellation is of Latin original, the latter of Greek, and both of the ſame import.

The Millenarians held, that after the coming of Antichriſt, and the deſtruction of all nations, which ſhall follow, there ſhall be a firſt reſurrection of the juſt alone: that all who ſhall be found upon earth, both good and bad, ſhall continue alive; the good, to obey the juſt, who are riſen, as their princes; the bad, to be conquered by the juſt, and to be ſubject to them: that Jeſus Chriſt will then deſcend from Heaven in his glory: that the city of Jeruſalem will be rebuilt, enlarged, embelliſhed, and its gates ſtand open night and day. They applied to this new Jeruſalem, what is ſaid in the Apocalypſe, ch. xxi. and to the temple, all that is written in Ezekiel xxxvi. Here, they pretended, Jeſus Chriſt will fix the ſeat of his empire, and reign a thouſand years with the ſaints, patriarchs and prophets, who will enjoy perfect and uninterrupted felicity.

This reign of our Saviour on earth is uſually ſtyled the millennium, or reign of a thouſand years.

MILLEPEDES, the common wood-louſe, an oblong inſect, with fourteen feet, notched along the ſides, rolling itſelf up into a round ball on being touched; found in cellars, and under ſtones and logs of wood in cold moiſt places; rarely met with in the warmer climates. Thoſe which have a white ſilver-like hue, are accounted the beſt; and the black the worſt.

MILLEPEDES have a faint diſagreeable ſmell, and a ſomewhat brackiſh, ſweetiſh, unpleaſant taſte. They are celebrated as reſolvents, aperients, and diuretics; in jaundices, aſthmas, ſcrophulous and other diſorders; but that their virtues are ſo great as they are generally ſuppoſed to be, may be juſtly queſtioned, at leaſt when given in the cuſtomary doſes. Two hundred have been taken every day for ſome time together without producing any remarkable effect: in large doſes, indeed, it is probable that their activity may be conſiderable; as they are ſaid to have ſometimes produced an univerſal heat and thirſt with a pain in the region of the pubes, and ſometimes a ſcalding of urine.

Theſe inſects may be commodiouſly ſwallowed entire, as they ſpontaneouſly contract themſelves, on being touched, into the form of a pill. In the ſhops they are commonly reduced into powder; for which purpoſe they are prepared, either by incloſing them in a thin canvas cloth, and ſuſpending them over hot ſpirit of wine in a cloſe veſſel, till they are killed by the ſteam and rendered friable; or by including them in a proper veſſel, and drying them with a very gentle heat. Of the extraction of their active matter by menſtrua, no direct experiments have been made: it is rather by expreſſion, than on the principle of extraction or diſſolution, that their virtues are commonly endeavoured to be obtained in a liquid form; though ſome liquors are generally added previouſly to the expreſſion, partly to improve their virtue for particular intentions, partly to preſerve the animal juice from corruption, and partly to render it more completely ſeparable. The college of Edinburgh directs directs two ounces of live millepedes to be ſlightly bruiſed, and digeſted for a night in a pint of Rheniſh wine, after which the liquor is to be preſſed through a ſtrainer.

MILLET, MILIUM, the ſeed of a plant which by conſent of authors, both ancient and modern, is refrigerating and drying; it is of bad juice, difficult of digeſtion, binds the belly, and generates flatulences; it is, however, well known to be a very grateful food to many nations at preſent. In former times it ſerved to make bread, under a dearth of better corn, as we are aſſured by Dioſcorides, Pliny, Galen, and others of the ancients. Among the Italians, ſays C. Bauhine, loaves made of millet, which are yellow, are eaten hot by many, not out of neceſſity, but for their ſweetneſs; but, when this bread is grown hard, it is quite black. Of the flour of millet and milk the Italians make fine cakes, which muſt be eaten as ſoon as dreſſed, or elſe they become glutinous, and ungrateful to the taſte. In former times they made a ſort of white puddings of millet, as Pliny tells us. And among the Coſſacks and Tartars, their principal food is millet, the crude meal of which they mix with the milk of mares, or with blood drawn from the crural vein of their horſes. A pudding, prepared of millet, boiled in milk, with an addition of butter, and ſugar ſprinkled over it, is much in requeſt among the Germans at preſent; and theſe puddings have been long ago introduced into England, and are ſtill in faſhion.

The flower of millet was formerly uſed in fomentations for the gripes, and for pains of the head and nerves; it was applied externally in bags, becauſe the uſe of it in cataplaſms was difficult, on account of its friability. If the membrane of the brain happens to be wounded, it is excellently conglutinated, ſays Archigenes, by infuſing thereon the juice of calaminth, and ſprinkling it with the dry flour of millet. A decoction of millet, with figs and raiſins, is called by Heurnius a noble ſudorific and diuretic. Or, take of a decoction of millet, boiled till it burſts, four ounces; white wine, two ounces. Let the patient take it hot. *Cheſneau. Laii Hiſt. Plant.*

Millet is diuretic and aſtringent; the ſeeds are of extraordinary ſervice in diſeaſes of the lungs, and exulcerations of the kidneys; made into a cataplaſm, they are anodyne and reſolvent. *Hiſt. Plant. adſcript. Boerh.*

Indian MILLET.—It delights in a fat and humid ſoil; for which reaſon ſome ſow it in their fields to correct their luxuriance: it was brought from India into Spain, Italy, and other warm countries: they ſow it in ſummer, and reap it in autumn.

The ſeed is like panic both in taſte and temperament. The pooreſt ſort of people in Italy, and the peaſants in the Paduan, grind the ſeed, and make it into loaves, which are friable, and afford but little nutriment, being black, difficult of digeſtion, and binding. It is more uſual to make puddings, or white pots, of the flour and milk. In Tuſcany they ſow it more for the ſake of feeding their poultry, than to ſerve as aliment for men. They, alſo, give it to their cows, horſes and ſwine. Of the pith of the ſtalks is prepared an excellent remedy for the ſtrumæ; the preparation of which ſee in the Bauhines and Matthiolus; which laſt author commends, alſo, the flowers, for uterine fluxes and the dyſentery. *Raii Hiſt. Plant.*

MILLING, in the manufacture of cloth, the ſame with fulling. See FULLING.

MILLING *of Silk* is an operation otherwiſe called throwing. See the article THROWING.

MILLION, in arithmetic, the number of ten hundred thouſand, or a thouſand times a thouſand. See NUMBER and NUMERATION.

MILT, in anatomy, a name ſometimes given to the ſpleen. See SPLEEN.

MILT, or MELT, is alſo a denomination by which ſome call the roes of fiſhes. See the article ROE.

MILVUS, the kite, in ornithology, a ſpecies of falcon, with a forked tail, a yellow cera, a brown body, and a whitiſh head. It is a very common bird with us, about the ſize of a large tame pigeon. See FALCON and KITE.

MIME, μιμος, in the ancient comedy, a perſon who acted any character by mere geſtures, and hence denominated pantomime. See PANTOMIME.

MIND, *Mens*, νους, a thinking intelligent being, otherwiſe called ſpirit, in oppoſition to matter or body. See the articles BODY and SPIRIT.

The culture of the human mind is more immediately taught in the ſciences of logic and ethics. See LOGIC and ETHICS.

When the mind, ſays Mr. Locke, turns its view inwards

wards upon itſelf, thinking is the firſt idea that occurs; wherein it obſerves a great variety of modifications, whence it frames to itſelf diſtinct ideas. See IDEA.

Thus the perception annexed to any impreſſion on the body by an external object, is called ſenſation; when an idea recurs without the preſence of the object, it is called remembrance; when ſought after by the mind, and brought again into view, it is recollected; when the ideas are taken notice of, and as it were regiſtered in the memory, it is attention; when the mind fixes its view on any idea, and conſiders it on all ſides, it is called ſtudy. See the articles SENSATION, REMEMBRANCE, &c.

MINE, in natural hiſtory, a place under ground, where metals, minerals, or precious ſtones, are dug up.

For gold and ſilver mines, the richeſt and moſt celebrated are in the Spaniſh Weſt Indies: iron mines are more abundant in France; copper mines are chiefly in Sweden and Denmark; lead and tin mines abound moſt in England; quickſilver mines in Hungary and Spain; diamond mines in Golconda; ſalt mines in Poland, &c.

Metallic-MINES are generally dug for in mountains, though it is probable plains may abound as much therewith, only theſe are commonly cultivated; beſides this, the waters will ſcarce allow them to dig: and as the metallic veins always run either horizontal or oblique, they are eaſieſt found on the ſides of eminences.

The metallic veins are commonly encompaſſed with a ſort of ſtone peculiar to the mine, and accompanied with ſeveral ſtrata of clay, gravel, rock, &c. By all theſe the miners know when they approach a vein.

They diſcover that there is a mine in a mountain by the mineral ſtones that fall from it, the mineral taſte of the waters, the quality of the exhalations, the difference between the earth over the mines, and that of the neighbouring parts; the firſt freezing on the adjacent places, when it thaws about the mines. Add to this, that the ground producing but little graſs, and that but pale, is an indication of a mine.

In ſome mines the metals are found at their firſt opening crude and imperfect, which yet in time, as ſome ſay, grow ripe and rich.

MINE, in the military art, denotes a ſubterraneous canal or paſſage, dug under the wall or rampart of a fortification, intended to be blown up by gun-powder.

The alley or paſſage of a mine is commonly about four feet ſquare; at the end of this is the chamber of the mine, which is a cavity about five feet in width and in length, and about ſix feet in height; and here the gunpowder is ſtowed. The ſauciſſe of the mine is the train, for which there is always a little aperture left. There are various kinds of mines, which acquire various names, as royal-mines, ſerpentine-mines, forked-mines, according as their paſſages are ſtraight, oblique, winding, &c. There are alſo mines made in the field, which are called fougades. See the article FOUGADE.

Mines are either dug within the body of the earth, as thoſe made by the beſieged to blow up the works of the beſiegers, before they make a lodgment on the covert-way; or in eminences and riſing grounds, as to make a breach in the ramparts, &c. or to blow up walls, or laſtly, to tear up rocks.

Two ounces of powder have been found, by experiment, capable of raiſing two cubic feet of earth; conſequently two hundred ounces, that is twelve pounds eight ounces, will raiſe two hundred cubic feet, which is only fifteen feet ſhort of a cubic toiſe, becauſe two hundred ounces joined together, have proportionably a greater force than two ounces, as being an united force. See GUN-POWDER.

All the turnings a miner uſes to carry on his mines, and through which he conducts the ſauciſſe, ſhould be well filled up with earth and dung; and the maſonry in proportion to the earth to be blown up, as 3 to 2. The entrance of the chamber of the mine ought to be firmly ſet with thick planks, in the form of a St. Andrew's croſs, ſo that the encloſure be ſecure, and the void places ſhut up with dung, or tempered earth. If a gallery be made below, or on the ſide of the chamber, it muſt abſolutely be filled up with the ſtrongeſt maſonry, full as long again as the height of the earth; for this gallery will not only burſt, but likewiſe obſtruct the effect of the mine. The powder ſhould always be kept in ſacks, which are opened when the mine is charged, and ſome of the powder ſtrewed about: the greater the quantity of earth to be raiſed, the greater is the effect of the mine, ſuppoſing it to have the due proportion of powder. Powder has the ſame effect upon maſonry as upon earth, that is, it will proportionably raiſe either with the ſame velocity.

The branches which are carried into the ſolidity of walls, do not exceed three feet in depth, and two feet ſix inches in width nearly; this ſort of mine is moſt excellent to blow up the ſtrongeſt walls.

The weight of a cubic foot of powder ſhould be 80 lb. one foot one inch cube will weigh 100 lb. and one foot two inches and eleven twelfths, 150 lb. and 200 lb. of powder will be one foot five inches cube; however, there is a diverſity in this, according to the quantity of ſalt-petre in the gun-powder.

If when the mines are made, water be found at the bottom of the chamber, planks are laid there, on which the powder is placed either in ſacks or barrels, of 100 lb. each. The ſauciſſe muſt have a clear paſſage to the powder, and be laid in an auget, or wooden trough, through all the branches. When the powder is placed in the chamber, the planks are laid to cover it, and others again acroſs theſe; then one is placed over the top of the chamber, which is ſhaped for that purpoſe: between that and thoſe which cover the powder, props are placed, which ſhore it up; ſome inclining towards the outſide, others to the inſide of the wall; all the void ſpaces being filled with earth, dung, brick, and rough ſtones. Afterwards planks are placed at the entrance of the chamber with one acroſs the top, whereon they buttreſs three ſtrong props, whoſe other ends are likewiſe propped againſt another plank ſituated on the ſide of the earth in the branch; which props being well fixed between the planks with wedges, the branch ſhould then be filled up to its entrance with the forementioned materials. The ſauciſſes which paſs through the ſide branches muſt be exactly the ſame length with that in the middle, to which they join: the part which reaches beyond the entrance of the mine, is that which conveys the fire to the other three; the ſauciſſes being of equal length will ſpring together. From a great number of experiments, it appears, 1. That the force of a mine is always towards the weakeſt ſide; ſo that the diſpoſition of the chamber of a mine does not at all contribute to determine this effect. 2. That the quantity of powder muſt be greater or leſs, in proportion to the greater or leſs weight of the bodies to be raiſed, and to their greater or leſs coheſion; ſo that you are to allow for each cubic fathom of looſe earth, 9 or 10 lb.

Firm earth or ſtrong ſand,	11 or 12
Fat clayey earth,	15 or 16
New maſonry not ſtrongly bound,	15 or 20
Old maſonry, well bound,	25 or 30

3. That the aperture, or entonnoir of a mine, if rightly charged, is a cone, the diameter of whoſe baſe is double the height taken from the center of the mine. 4. That when the mine has been over-charged, its entonnoir is nearly cylindrical, the diameter of the upper extreme not much exceeding that of the chamber. 5. That beſides the ſhock of the powder againſt the bodies it takes up, it likewiſe cruſhes all the earth that borders upon it, both underneath and ſideways.

To charge a mine ſo as to have the moſt advantageous effect, the weight of the matter to be carried muſt be known; that is, the ſolidity of a right cone, whoſe baſe is double the height of the earth over the center of the mine: thus having found the ſolidity of the cone in cubic fathoms, multiply the number of fathoms by the number of pounds of powder neceſſary for raiſing the matter it contains; and if the cone contains matters of different weights, take a mean weight between them all, always having a regard to their degree of coheſion.

As to the diſpoſition of mines, there is but one general rule, which is, that the ſide towards which one would determine the effect be the weakeſt, but this varies according to occaſions and circumſtances.

The calculation of mines is generally built upon this

hypotheſis,

hypotheſis, that the entonnoir of a mine is the fruſtum of an inverted cone, whoſe altitude is equal to the radius of the excavation of the mine, and the diameter of whoſe leſſer baſe is equal to the line of leaſt reſiſtance; and though theſe ſuppoſitions are not quite exact, yet the calculation of mines deduced from them have proved ſucceſsful in practice; for which reaſon this calculation ſhould be followed, till a better and more ſimple be found out.

M. de Valliere found that the entonnoir of a mine was a paraboloid, which is a ſolid generated by the rotation of a ſemi-parabola about its axis; but as the difference between theſe two is very inſignificant in practice, that of the fruſtum of a cone may be uſed. See the article PARABOLOID.

MINERAL, in natural hiſtory, in general, denotes foſſil, and is applied to any body dug out of the earth. In this ſenſe minerals are divided into claſſes; the one fuſible and malleable, which are what we properly call metals; the others want theſe two properties, and are what we ſtrictly call minerals.

MINERAL, in a more accurate ſenſe, denotes a compound foſſil, in which there is ſomething diſcovered, in all reſpects like metals, only that it is not malleable, joined with ſome other foſſil, as ſalt, ſulphur, ſtone, or earth, ſuch as antimony, cinnabar, biſmuth, &c.

Some aſcribe the formation of minerals to the action of the ſun without; ſome to the central fire within; and ſome think the cold does all by condenſing and congealing certain juices of the earth.

The minerals, metals, and ſtones, lie in beds ever ſince the flood, if not from the creation: yet it is highly probable they have a faculty of growing in their reſpective beds, as Mr. Boyle thinks. Among other inſtances he adds, that in the foreſt of Dean in Glouceſterſhire, the beſt iron, and in the greateſt quantities, are found in the old cinders, which they melt over again. This ſome impute to the negligence of former melters; but Mr. Derham imagines it rather owing to the new impregnations of the old ore or cinders from the air.

MINERAL *Waters*, in medicine, all thoſe wherein any medicinal virtues, beſides thoſe of common water, are found.

Theſe mineral waters are of various kinds, but they are conſidered under the general titles of chalybeate, purgative, and alterative. The more uſeful and commodious additions for examining theſe three kinds of mineral waters, are, according to Dr. Shaw, galls, ſyrup of violets, and oil of tartar per deliquium. Galls diſcover in them any ſmall proportion of vitriol or diſſolved iron, as having the property of immediately ſtriking a purple or black colour in all waters where any ſuch ſubſtance is lodged. Spirit of violet, in the ſame manner, diſcovers any ſmall predominancy of an acid, or alkali therein, by changing the water red if acid, and green if alkali preſides. Oil of tartar diſcovers any ſmall proportion of earthy matter leſs capable of diſſolving in water than that ſalt, by precipitating ſuch earthy matter in form of a white cloud to the bottom of the containing glaſs, where it collects and appears like a ſubtile white powder. Theſe particulars may be ſhewn and proved ſatisfactorily by adding to pure water a little of a known acid alkali, diſſolved iron, and ſubtile earth, or fine light ſediment of an earthy water; applying the ſyrup of violets, galls, and oil of tartar reſpectively.

MINERVALIA, in Roman antiquity, feſtivals celebrated in honour of Minerva, in the month of March; at which time the ſcholars had a vacation, and uſually made a preſent to their maſters, called from this feſtival minerval.

MINIATURE, a delicate kind of painting, diſtinguiſhed from all others by the ſmallneſs of the figures; its being performed with dots or points inſtead of lines; by the faintneſs of the colouring; its requiring to be viewed very near; and by its being uſually done on vellum. See PAINTING and REDUCTION.

Your vellum muſt be glued to a copper-plate, or a piece of thin board, exactly of the ſame ſize with the intended piece; in doing which, the fair ſide of the vellum ſhould be moiſtened with a fine wet linen; and a piece of white paper being put upon the back of it, it is to be applied to the plate or board, and ſtretching it upon it equally in all directions, the vellum ought to be every way a finger's breadth larger than what you glue it to, in order to be doubled over and glued behind. When your piece is ſketched out upon the vellum with a pencil, you muſt, with a little thin carmine, run over all the ſtrokes that they may not be defaced in working, and this done clean your vellum with crumb of bread. In laying on the colours, begin with ſketching or drawing with large, bold, but clear ſtrokes, like thoſe who paint in oil: your lights muſt at firſt be ſomething brighter, and your ſhades not quite ſo dark as is required in finiſhing, becauſe in ſtrippling upon them you ſtrengthen the colour, which if too deep at firſt, would in finiſhing become too dark. Endeavour alſo to drown your colours into each other, that no line of ſeparation may be ſeen between them; to this purpoſe ſoften your ſtrokes with the colours on each ſide of them, ſo that they may be blended and confounded with each other. There are ſeveral ways of ſtrippling, and every painter has his manner; ſome do it with round points, others make them longiſh; others again hatch fine ſtrokes, croſſing each other in all directions, till the whole appears as if ſtrippled or wrought with points; this laſt method is the beſt, boldeſt, and ſooneſt perfected: the artiſt ſhould here accuſtom himſelf to be rich, mellow, and ſoft in his work; the points muſt ſeem in a manner loſt in the ground they are wrought upon, and appear but juſt enough to ſhew that the piece is ſtrippled. When the work ſeems finiſhed, heightening it a little has a fine effect; that is, ſtrengthening the lights with touches of a paler colour than at firſt, which muſt be ſoftened away into the reſt.

MINIM, in muſic, a note equal to two crotchets, or half a ſemibreve.

MINIMS, a religious order in the church of Rome, founded by St. Francis De Paula, towards the end of the fifteenth century. Their habit is a coarſe black woollen ſhift, with a woollen girdle, of the ſame colour, tied in five knots. They are not permitted to quit the habit and girdle night nor day. Formerly they went bare-footed, but are now allowed the uſe of ſhoes.

MINIMUM, in mathematics, denotes the leaſt quantity attainable in any given caſe.

The common methods of reſolving problems relating to the minima, are the ſame with thoſe we have ſhewn under the article MAXIMUM. But there are however ſome inquiries of a higher nature concerning problems *de Maximis et Minimis*, which it may be worth while to illuſtrate.

Let therefore KL (pl. LXXXVIII. *fig.* 5.) be a right line given in poſition, AK a perpendicular upon KL from a given point A, E any point in this line; join AE, ſuppoſe KE to be deſcribed uniformly with any given velocity a, and AE to be deſcribed uniformly with any given velocity u, that is leſs than a. Let L be taken upon the right line KL, ſo that AL may be to KL, as a is to u; and the difference of the times in which the right lines AE and KE will be deſcribed by the reſpective velocities u and a (or $\frac{AE}{u} - \frac{KE}{a}$) will be leaſt when E falls upon L; that is, when the angle KAE is ſuch, that its ſine is to the radius as u is to a: for let KH and EV be perpendicular on AL in H and V reſpectively, and AR be taken upon AL equal to AE; then HV will be to KE as KL is to AL, or (by conſtruction) as u to a; conſequently HV will be deſcribed with the velocity u in the ſame time that KE is deſcribed with the velocity a; therefore the exceſs of the time in which AE is deſcribed with the velocity u, above the time in which KE is deſcribed with the velocity a, is equal to the time in which AE−HV, or AR−HV, or AH+VR is deſcribed with the velocity u; and becauſe AH is invariable, this time is leaſt when VR vaniſhes; that is, when E falls upon L, and the ſine of the angle KAE is to the radius as a to u. The ſame will appear from an algebraical inveſtigation; thus, put AK $= b$, AE $= x$; then KE $= \sqrt{xx-bb}$, whence $\frac{AE}{u} - \frac{KE}{a}$, or $\frac{x}{u} - \frac{\sqrt{xx-bb}}{a}$ muſt

a minimum; therefore $a\dot{x} - \frac{u \times \dot{x}}{\sqrt{xx-bb}} = 0$; consequently $a \times KE = u \times AE$, or $AE : KE :: a : u$, the same as before.

Now let GAD (*fig.* 6.) be a curve of any kind, GH the abscissa, and HD its corresponding ordinate rightly applied, and AE a tangent to any point A of the curve. Draw GF parallel to DH, which produce at pleasure; draw FC parallel to GH, and produce DH to C. From A draw AP parallel to DC, produce PA to K, and draw KE parallel to GH. It appears from above, that if AK be given, and a and u denote any given or invariable quantities, then $AE \times a - KE \times u$ (or $\frac{AE}{u} - \frac{KE}{a}$) is a minimum, when $KE : AE :: u : a$, or $a \times KE = u \times AE$. Let the base $FP = x$, the ordinate $PA = y$, the arch $GA = s$, $AK = \dot{y}$, $AE = \dot{s}$, and $KE = \dot{x}$. Now if V and u represent any quantities compounded from the powers of y (so as to be of the same value when y is the same), and if $\dot{y}$ be given, then $V\dot{s} - u\dot{x}$, and $\frac{\dot{s}}{u} - \frac{\dot{x}}{V}$ are minima, when $V\dot{s} = u\dot{x}$. From this it follows, that if GAD be the whole curve, and DH the difference of the ordinates at G and D be given, then the fluent of $V\dot{s} -$ flu. $u\dot{x}$, or the flu. $\frac{\dot{s}}{u} -$ flu. $\frac{\dot{x}}{V}$ shall be a minimum, when the nature of the figure is defined by the equation $V\dot{x} = u\dot{s}$. Therefore, supposing this to be the equation of the curve, and DH to be given, if the fluent of $V\dot{s}$ be also given, then the fluent of $u\dot{x}$ shall be a maximum; or if the latter fluent be given, then the former shall be a minimum: and if the fluent of $\frac{\dot{s}}{u}$ be given, that of $\frac{\dot{x}}{V}$ shall be a maximum; or if the fluent of $\frac{\dot{x}}{V}$ be given, the fluent of $\frac{\dot{s}}{u}$ shall be a minimum. If the base FC or GH, together with DH, be given, and the fluent of $V\dot{s}$ be given or invariable, then the fluent of $u\dot{x}$ will be a maximum or minimum, when the equation of the curve is $V\dot{x} = e \pm u \times \dot{s}$, where e denotes an invariable quantity that may be positive or negative, or vanish.

Suppose therefore $V = A + By + Cyy + Dy^3 +$, &c. and $u = a + by + cy^2 + dy^3$, &c. where A, B, C, &c. and a, b, c, &c. denote any invariable co-efficients that may be positive or negative, any of which may be supposed to vanish; and the fluent of $V\dot{s} - u\dot{x}$; that is, of $\dot{s} \times \overline{A \times By + Cyy + Dy^3}$, &c. $- \dot{x} \times \overline{a + by + cyy + dy^3 +}$ &c. shall be a minimum, when the equation of the figure is $\dot{x} \times \overline{A + By + Cyy + Dy^3 +}$ &c. $= \dot{s} \times \overline{a + by + cyy +}$ &c. the ordinate DH being given; therefore if the fluent of $\dot{s} \times \overline{A + By + Cyy +}$ &c. be also given, the fluent of $\dot{x} \times \overline{a + by + cyy}$ &c. shall be a maximum; or if the latter be given, the former shall be a minimum: and if the base FC or GH be given with DH and the fluent of $\dot{s} \times \overline{A + By + Cyy +}$ &c. then the fluent of $\dot{x} \times \overline{a + by + cyy +}$ &c. shall be a maximum or minimum, when $\dot{x} \times \overline{A + By + Cyy +}$ &c. $= \dot{s} \times \overline{e \mp A + By + Cyy +}$ &c. Of which theorem it is an obvious, but a particular case only, that if the nature of the figure be defined by the last equation, and GH, DH, with the fluents of $A\dot{s}$, $By\dot{s}$, $Cy^2\dot{s}$, &c. $by\dot{x}$, $cyy\dot{x}$, $dy^3\dot{x}$, &c. be all given or invariable, one only excepted, this last fluent shall be either a maximum or minimum.

For example, the points G and D being given, if the periphery GAD (or the fluent of $A\dot{s}$) be also given, the area FGADC (or the fluent of $y\dot{x}$) is a maximum or minimum, when $A\dot{x} = \dot{s} \times \overline{e \pm A \pm By}$; that is, when GAD is an arch of a circle. If the surface generated by the arch GAD about the axis FC (or the fluent of $By\dot{s}$) be given, then the solid generated by the figure FGADC about the same axis (or the fluent of $cyy\dot{x}$) is a maximum or minimum, when $By\dot{x} = \dot{s} \times \overline{e \mp cyy}$; and when $e = 0$, this again is a circle. If the perimeter GAD (or the fluent of $A\dot{s}$) be given, the solid generated by FGADC about the axis FC is a maximum or minimum, when $A\dot{x} = \dot{s} \times \overline{e \pm cy^2}$, and GAD is then the elastic curve.

The late eminent mathematician Mr. Thomas Simpson gives (p. 101 of his Miscellaneous Tracts) the following general rule for the solution of problems of this kind.

Take the fluxions of all the proposed expressions (as well that respecting the maximum or minimum, as of the others whose fluents are to be given quantities) making that quantity, and likewise its fluxion, invariable, whereof the fluxion (as well as the quantity itself) enters into the said expressions; and having divided every where by the fluxion of the other quantity made variable, let the quantities hence arising, joined to general co-efficients 1, e, f, g, &c. be united into one sum, and the whole be made equal to nothing; from which equation (wherein the values of e, f, g, &c. may be either positive, or negative, or nothing, as the case requires) the required relation of the two variable quantities will be truly exhibited.

If the abscissa AP (*fig.* 7.) of a curve AQC be denoted by x, and the ordinate PQ by y, and p be taken to express the measure of the circumference of a circle whose diameter is unity; it is well known that the several fluxions of the abscissa AP, curve-line AQ, area APQ, superficies of the generated solid (by a rotation about the axis AP), and of the solid itself, will be respectively represented by $\dot{x}$, $\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}$, $y\dot{x}$, $2py\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}$ and $py^2\dot{x}$; if therefore the fluxions of those different expressions be taken as before (making $\dot{x}$ alone variable), we shall get $1 + \frac{e\ddot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} + fy + \frac{gy\dot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} + hy^2 = 0$; being a general equation for determining the relation of x and y, when any one of those five quantities (viz. the abscissa, curve-line, area, superficies, or solid) is a maximum or minimum, and all, or any number of the others, at the same time, equal to given quantities; wherein the co-efficients e, f, g, and h, may be positive, negative, or may vanish, as the case proposed may require. Thus, for instance, if the length of the curve only be given, and the area corresponding is required to be a maximum, our equation will then become $\frac{e\ddot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} + fy = 0$, or $a^2\dot{x}^2 = y^2\overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}$ (by making $a = -\frac{e}{f}$); whence $\dot{x} = \frac{y\dot{y}}{\sqrt{aa+yy}}$ and consequently $x = a - \sqrt{aa-yy}$, or $2ax - xx = yy$; answering to a circle; which is therefore more capacious than any other under equal bounds.

If, together with the ordinate (which is always supposed given), the abscissa at the end of the fluent be given likewise, and the superficies generated by the rotation of the curve about its axis be a minimum; then from the same equation we shall have $1 + \frac{gy\ddot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} = 0$, whence (making $a = -\frac{1}{g}$) $\ddot{x}$ is found $= \frac{a\dot{y}}{\sqrt{yy-aa}}$; and from thence $x = a \times$ hyp. log. $\frac{y+\sqrt{yy-aa}}{a}$; which equation, by being impossible when y is less than a, shews that the curve (which is here the catenaria) cannot possibly meet the axis about which the solid is generated, and consequently that the case will not admit of any minimum, unless the first or least given value of y, exceeds a certain assignable magnitude.

When any, or all of the above specified quantities are given, and the contemporary fluent of some other expression, as $y^m\dot{y}^{1-2n} \times \overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}$, is required to be a maximum or minimum, our equation (by taking the fluxion of this last expression, and joining it to the former) will then be $\overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}^{n-1} \times 2n\dot{x}y^m\dot{y}^{1-2n} + d + \frac{e\ddot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} + fy + \frac{gy\dot{x}}{\sqrt{\dot{x}\dot{x}+\dot{y}\dot{y}}} + hy^2 = 0$; which, when $m = 1$ and $n = -1$, will be that defining the solid of the least resistance; and this, when the length of the axis only is supposed to be given (without farther restrictions) will be expressed by $\overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}^{-2} \times -2\dot{x}y\dot{y}^3 + d = 0$, or $2y\dot{y}^3\dot{x} = d \times \overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}^2$; being the case first considered by Sir Isaac Newton. — If both the length and the solid content be given, the equation will be $d + hy^2 - 2\dot{x}y\dot{y}^3 \times \overline{\ddot{x}\dot{x}+\dot{y}\dot{y}}^{-2} = 0$; but if, besides these, the superficies is given likewise,

wiſe, it will then be $d + by^2 - \frac{gy\dot{x}}{\sqrt{\ddot{x}\ddot{x}+\dot{y}\dot{y}}} - 2\dot{x}y\dot{y}^3 \times \overline{\ddot{x}\ddot{x}+\dot{y}\dot{y}}^{-2} = 0$.

MINION, a piece of cannon, at preſent but little uſed in the field. For its length, bore, and the weight of the ball it carries, ſee CANNON.

MINIUM, red lead, a preparation of lead uſed both in pharmacy and painting.

Minium is commonly prepared from lead calcined into a greyiſh powder by keeping it melted over the fire. This powder, ground in mills, is further calcined, in a reverberatory furnace, under a low arch, and frequently ſtirred with an iron rake, to prevent its melting and running into clots, and to expoſe a freſh ſurface to the action of the air and flame. The calcination laſts two or three days. The increaſe of weight is ſaid to amount to one fourth the weight of the lead; and the lead recovered from the minium to be one twentieth leſs than the original weight of the metal. If the minium be further calcined, the increaſe is no more; but the quantity of lead recoverable proves leſs in proportion to the vehemence and continuance of the calcination.

The largeſt quantities of minium are made at Venice, and in England. The Venetians employ for the beſt ſort, ceruſſe, or white lead: for the middling ſort, the refuſe plates of lead remaining after the making of ceruſſe; the worſt kind is prepared from litharge. See the articles LEAD, LITHARGE, &c.

MINOR, in law, is an heir, either male or female, before they arrive at the age of twenty-one; during the minority of ſuch, they are uſually incapable of acting for themſelves. See INFANT.

MINOR, in logic, the ſecond propoſition of a regular ſyllogiſm. See SYLLOGISM.

MINOR, in muſic, ſignifies leſs, and is applied to certain concords or intervals, which differ from others of the ſame denomination by half a tone. Thus we ſay, a third minor, meaning a leſs third: a ſixth major and minor.

MINOTAUR, *Minotaurus*, in antiquity, a fabulous monſter much talked of by the poets, feigned to be half man and half bull.

The minotaur was brought forth by Paſiphae, wife of Minos, king of Crete. It was ſhut up in the labyrinth of that iſland, and at laſt killed by Theſeus.

MINT, the place where the king's money is coined. See COINAGE.

MINT. See MENTHA.

MINUET, in muſic, a very graceful kind of dance, which conſiſts of a coupee, a high ſtep, and a ballance; it begins with a beat, and its motion is triple.

MINUTE, in geometry, the ſixtieth part of a degree of a circle. See CIRCLE and DEGREE.

MINUTE *of Time*, the ſixtieth part of an hour. See HOUR.

MINUTE, in architecture, uſually denotes the ſixtieth, ſometimes the thirtieth part of a module. See the article MODULE.

MIRACLE is defined by Dr. Clarke, to be a work effected in a manner different from the common and regular method of Providence, by the interpoſition either of God himſelf, or ſome intelligent agent ſuperior to man.

MIRROR, *Speculum*, in catoptrics, any poliſhed body, impervious to the rays of light, and which reflects them equally.

Mirrors were anciently made of metal; but at preſent are generally ſmooth plates of glaſs, tinned or quick-ſilvered on the back part, and called looking-glaſſes. See LOOKING-GLASS.

The doctrine of mirrors depends wholly on that fundamental law, that the angle of reflection is always equal to the angle of incidence. See INCIDENCE.

Let EH (plate LXXXVIII. *fig.* 8.) be a concave mirror, V its vertex, and C the center of its concavity. Let A be a ray of the ſun's light incident on the point E, and draw EC, which will be perpendicular to the mirror in the point E; make the angle CEF equal to the angle AEC, then ſhall EF be the reflected ray. Thus alſo HF will be the reflected ray of the incident one DH, at an equal diſtance on the other ſide of the axis BV.

If now the poiuts E and H be taken very near the vertex V, we ſhall have EF, or HF, very nearly equal to FV; but EF = FC; therefore FV = FC = ½CV. That is, the focal diſtance FV of parallel rays will be at the diſtance of half the radius CV of the concavity of the mirror, from the vertex V, in the axis BV. After the ſame manner, a convex mirror is ſhewn to reflect the rays AE, DH, (*fig.* 9.) into EF, HF, as if they came diverging from a point *f* in the axis CV, which is half the radius CV diſtant from the vertex V. But ſince the rays do not actually come at, or from the focus *f*, it is called the imaginary or virtual focus. See FOCUS.

Parallel rays falling directly on a plane ſpeculum are reflected back upon themſelves; if they fall obliquely, they are reflected in the ſame angle, and parallel as they fell. Hence there is no ſuch thing, properly ſpeaking, as a focus belonging to a plane ſpeculum, neither real nor virtual.

The focus F, or *f*, of parallel rays, is called the ſolar focus; becauſe in that the image of the ſun is formed, and of all objects very remote. But the focus of any object ſituated near the mirror will have its diſtance from the vertex more or leſs than half the radius; the rule in all caſes being as follows:

Multiply the diſtance of the object into the radius of the mirror, and divide the product by the ſum of the radius and twice the diſtance of the object; the quotient will be the focal diſtance of a convex mirrour.

Again, for a concave mirror, the ſame product of the radius into the diſtance of the object, divided by the difference of radius, and twice the diſtance of the object, will give the focal diſtance VF or V*f*. And here we are to obſerve, that, as twice the diſtance of the object is leſſer or greater than the radius, ſo the focus will be poſitive or negative, that is, behind the glaſs or before it.

The image of the object is formed in the focus proper to its diſtance: And, ſince the writers on optics demonſtrate that the angles under which the object OB (*fig.* 10.) and its image IW are ſeen from the center or vertex of the mirror C are always equal, it follows, that the image IW will be always in proportion to the object OB, as the focal diſtance VF to the object's diſtance GV. The poſition of the object will be always erect at a poſitive focus, or behind the ſpeculum; diminiſhed by a convex, and magnified by a concave one. Hence, ſince a convex has but one, viz. an affirmative focus; ſo it can never magnify any object, howſoever poſited before it.

The poſition of the image in a negative focus, or that before the glaſs, will be ever inverted; and, if nearer the vertex than the center C, it will be leſs; if farther from it, it will be greater than the object; but in the center it will be equal to the object, and ſeem to touch it.

The image formed by a plane ſpeculum is erect; large as the life; at the ſame apparent diſtance behind the glaſs as the object is before it; and on the ſame ſide of the glaſs with the object. Thoſe properties render this ſort of mirror of moſt common uſe, viz. as a looking-glaſs.

If the rays fall directly, or nearly ſo, on a plane mirror, and the object be opake, there will be but one ſingle image formed, or at leaſt be viſible; and that by the ſecond ſurface of the ſpeculum, and not by the firſt, through which the rays do moſt of them paſs.

But if the object be luminous, and the rays fall very obliquely on the ſpeculum, there will be more than one image formed, to an eye placed in a proper poſition to view them. The firſt image being formed by the firſt ſurface will not be ſo bright as the ſecond, which is formed by the ſecond ſurface. The third, fourth, &c. images are produced by ſeveral reflections of the rays between the two ſurfaces of the ſpeculum; and, ſince ſome light is loſt by each reflection, the images from the ſecond will appear ſtill more faint and obſcure, to the eighth, ninth, or tenth, which can ſcarcely be diſcerned at all.

Mirrors may be divided into plane, concave, convex, cylindrical, conical, parabolical, and elliptical.

The beſt manner of preparing convex mirrors hitherto known is given us by Wolfius, thus:

5 JA 59

Melt one part of tin, another of marcaſite, together; and to this maſs add two parts of mercury; as ſoon as the mercury begins to evaporate into ſmoke, the whole is to be thrown into cold water, and when well cooled, the water decanted off. Strain the mixture through two or three folds of linen cloth; and what is thus ſecreted pour into the cavity of a glaſs-ſphere, which is to be turned gently round its axis, till the whole ſurface be covered; the reſt being reſerved for future uſe. If the ſphere were of coloured glaſs, the mirror will be ſo too. And in like manner may conic, elliptic, cylindric, and other mirrors be made. See FOLIATING.

For elliptical, parabolical, and hyperbolical mirrors, the mould is to be thus prepared; on a wooden or braſs plane, deſcribe an ellipſis A B (*fig.* 11.), alſo a parabola or hyperbola, C D (*fig.* 12.); then cut out the figure from the plane with all the accuracy imaginable.

To the elliptic figure fit an axis, as E F, with two fulcra to ſuſtain it, &c. and a handle to move it. Lay a quantity of the clay under it, and turn about the axis by the handle, till the plane A B have impreſſed the elliptical figure exactly thereon.

The axis of the parabolical or hyperbolical figure C D is to be fixed at the vertex, ſo as to be always erect. This is to be turned about, till it have given its figure to the clay round it.

The part of the mould thus formed is to be dried, and then ſmeared over with fat, &c. then a convex mould is to be made by putting a quantity of the ſame clay into the cavity thus formed. The latter is called the male, as the former is the female mould. The male mould, when dry, is to be applied within the female ſo as to leave the intended thickneſs of the mirror between them. Theſe mirrors are very difficult to be made, as the figure thereof is apt to be damaged in the grinding. See GRINDING.

The properties of cylindrical mirrors are, 1. The dimenſions of objects correſponding lengthwiſe to the mirror are not much changed; but thoſe correſponding breadthwiſe have their figure altered and their dimenſions leſſened the farther from the mirror; whence ariſes a very great diſtortion. 2. If the plane of the reflection cut the cylindric mirror through the axis, the reflection is performed in the ſame manner as in a plane mirror; if parallel to the baſe, the reflection is the ſame as in a ſpherical mirror; if it cut it obliquely, the reflection is the ſame as in an elliptic mirror. Hence, as the plane of reflection never paſſes through the axis of the mirror, except when the eye and objective line are in the ſame plane; nor parallel to the baſe, except when the radiant point and the eye are at the ſame height; the reflection is therefore uſually the ſame as in an elliptic one. 3. If a hollow cylindric mirror be directly oppoſed to the ſun, inſtead of a focus of a point, the rays will be reflected into a lucid line parallel to its axis, at a diſtance ſomewhat leſs than a fourth of its diameter. Hence ariſes a method of drawing anamorphoſes, that is, wild deformed figures on a plane, which appear well proportioned, when viewed in a cylindric mirror.

In an elliptic mirror, if a ray ſtrike on it from one of its focuſes, it is reflected into the other.

In parabolic mirrors, as all the rays they reflect meet in one point, they make the beſt burning-glaſſes.

MISCHNA, or MISNA, the code or collection of the civil law of the Jews. The Jews pretend, that when God gave the written law to Moſes, he gave himſelf alſo another not written, which was preſerved by tradition among the doctors of the ſynagogue, till Rabbi Juda, ſurnamed the Holy, ſeeing the danger they were in, through their diſperſion, of departing from the traditions of their fathers, judged it proper to reduce them to writing.

MISDEMEANOUR, in law, ſignifies a heinous offence or fault, particularly in the execution of an office.

MISERERE MEI, in medicine, a name by which ſome call the iliac paſſion. See ILIAC PASSION.

MISLETOE, in botany, a buſhy evergreen plant; with woody branches variouſly interwoven; firm narrow leaves, narroweſt at the bottom, ſet in pairs; and imperfect white flowers in their boſoms, followed each by a tranſparent white berry containing a ſingle ſeed. It grows only on the trunks and branches of trees, and may be propagated by rubbing the glutinous berries on the bark that the ſeeds may adhere.

The leaves and branches of miſletoe, formerly recommended as ſpecifics in convulſive and other nervous diſorders, and now fallen into general neglect, do not appear to have any conſiderable medicinal power. Inſtances have indeed been produced of their ſeeming to prove beneficial: but as there are, perhaps, no diſorders whoſe nature is ſo little underſtood, whoſe cauſes are ſo various, and whoſe mitigations and exaſperations have leſs dependence upon ſenſible things; there are none in which medicines operate more precarioufly, and in which the obſerver is more liable to deception.

MISPRISION ſignifies in general, ſome neglect or over-ſight, as where a perſon is privy to a treaſon or felony committed by another, and neglects to reveal it to the king or his council, or to a magiſtrate, but entirely conceals them; this is called miſpriſion of thoſe crimes. In caſes of miſpriſion of treaſon, the offender is to be impriſoned for life, and to forfeit his goods and chattels, together with the profits of his lands, &c. but in miſpriſion of felony, the offender is only to be puniſhed with fine and impriſonment, and to remain in priſon till the fine is paid.

MISSAL, the Romiſh maſs-book, containing the ſeveral maſſes to be ſaid on particular days.

MISSEL-BIRD, in zoology, the common Engliſh name of the larger ſpecies of thruſh, called alſo the ſhrite, and by authors the turdus viſcivorus major. It is much larger than any other of the thruſh kind. Its legs and feet are yellow; its head of a browniſh lead colour; and its back, tail, and rump, of the ſame colour, with an admixture of yellow; but in the ſummer months it a little changes its colour, and becomes more grey, or of the colour of unripe pickled olives; its throat, breaſt, and belly, are all variegated with black ſpots; the middle of its belly whitiſh, and the upper part of its breaſt, and part of its ſides, and the under feathers of its tail yellowiſh. *Ray's Ornithology.*

MISSIONARIES, ſuch eccleſiaſtics as are ſent by any Chriſtian church, into pagan or infidel countries, to convert the natives, and eſtabliſh the Chriſtian religion among them.

MISSIVE, ſomething ſent to another, as miſſive letters, meaning letters ſent from one to another upon buſineſs, in contradiſtinction to letters of gallantry, points of learning, diſpatches, &c.

MIST, the ſame with fog. See FOG.

MITE, a ſmall coin formerly current, equal to about one third part of a farthing.

It alſo denotes a ſmall weight uſed by the moneyers. It is equal to the twentieth part of of a grain, and is divided into twenty-four doits.

MITHRIDATE, *Mithridatium*, in pharmacy, an antidote, in form of an electuary, chiefly againſt poiſon.

It is ſo called from its inventor Mithridates, king of Pontus; though its preſent form is different from what he made it.

It is one of the capital officinals, conſiſting of a vaſt number of ingredients, many of which might have been better left out, as they bear no affinity to the main deſign of the whole. It would make a much better medicine, if the other ingredients of the right intention were proportionably increaſed, ſo as to make the opium ſtill bear the ſame proportion to the whole.

MITHRIDATE is greatly uſed as a cordial, an opiate, and a ſudorific. Its doſe is from one ſcruple to two drachms, and is a much better medicine, as a cordial and alexipharmic, than the Venice treacle.

MITRALES-VALVULÆ, *Mitral Valves*, in anatomy, two valves ſituated in the left ventricle of the heart, at the ngreſs of the pulmonary vein, ſerving to hinder the ingreſs and regreſs of the blood from the heart into the veins again, while they are conſtricted. See the article HEART.

MITRE, a ſacerdotal ornament worn on the head by biſhops and certain abbots, on ſolemn occaſions; being a ſort of a cap, pointed and cleft at top.

MITTIMUS, as generally uſed, hath two ſignifications: 1. It ſignifies a writ for removing and transferring

ing of records from one court to another. 2. It ſignifies a precept or command in writing, under the hand and ſeal of a juſtice of the peace, directed to the goaler or keeper of ſome priſon, for the receiving and ſafe keeping of an offender charged with any crime, until he be delivered by due courſe of law.

MIXT, or MIXT BODY, in philoſophy and chemiſtry, that which is compounded of different elements or principles; in which ſenſe it ſtands contradiſtinguiſhed from ſimple or elementary, which is applied to bodies conſiſting of one principle only, as the chemiſts take ſulphur, ſalt, &c. to do. The buſineſs of chemiſtry is, to reſolve mixt bodies into their principles, or component parts.

MIXT ACTION, in law, is an action partly real and partly perſonal, which lies both for the thing detained, and againſt the perſon of the detainer. See the article ACTION.

MIXTURE, a compound, or aſſemblage of ſeveral different bodies in the ſame maſs.

MIZEN, the aftmoſt or hindmoſt ſtanding ſail in a ſhip of three maſts. We ſay ſtanding ſail, becauſe there can occaſionally be ſet ſeveral flying ſails behind it, as the driver, ringſail, &c.

The mizen is in ſhape a ſort of trapezia or oblong, peaked or ſloped at the upper end. It is ſometimes faſtened above to a gaff, and ſometimes to a yard; the gaff only reaches into the maſt, but the yard croſſes the maſt at oblique angles, the lower end reaching almoſt down to the deck.

MIZEN-MAST, the maſt on which the mizen is faſtened, which is the aftmoſt or hindmoſt in the ſhip. See the article MAST.

MIZEN-BRAILS.	See	BRAILS

MNEMONICS, an art invented for the aſſiſtance of the memory.

The word is derived from the Greek μνημονικος, ſomething relating to the memory, which is formed from μνημων, mindful; and that from μναομαι, to remember. See MEMORY.

MOAR-LOVRE, in huſbandry, a ſort of blight, which happens moſtly on light land, from the earth's ſinking away from the roots, ſo that the plants fall down to the earth.

To remedy this, they turn a ſhallow furrow againſt the rows, when they are ſtrong enough to bear it, and when the mould is fine and dry; for then the motion of the ſtalks by the wind, will cauſe ſuch earth to run through the rows, and ſettle about the roots, and cover them.

MOAT, or DITCH, in fortification, a deep trench dug round the rampart of a fortified place, to prevent ſurprizes.

The brink of the moat, next the rampart, is called the ſcarpe; and the oppoſite one, the counterſcarpe.

A dry moat round a large place, with a ſtrong garriſon, is preferable to one full of water; becauſe the paſſage may be diſputed inch by inch, and the beſiegers when lodged in it, are continually expoſed to the bombs, granades, and other fire-works, which are thrown inceſſantly from the rampart into their works. In the middle of dry moats, there is ſometimes another ſmall one, called cunette: which is generally dug ſo deep, till they find water to fill it.

The deepeſt and broadeſt moats are accounted the beſt, but a deep one is preferable to a broad one: the ordinary breadth is about twenty fathoms, and the depth about ſixteen.

To drain a moat that is full of water, they dig a trench deeper than the level of the water, to let it run off; and then throw hurdles upon the mud and ſlime, covering them with earth or bundles of ruſhes, to make a ſure and firm paſſage.

MOBILE, or PRIMUM MOBILE, the ninth ſphere in the Ptolemaic ſyſtem of aſtronomy. See the article PTOLEMAIC.

MODE, *Modus*, in philoſophy, denotes the manner of a thing's exiſtence, which is two-fold, viz. ſimple or mixed.

Simple modes are only combinations of the ſame ſimple idea: thus by adding units together, in diſtinct ſeparate collections, we come by all the ſeveral modes of numbers, as a *dozen*, a *ſcore*, a *thouſand*, &c. Mixed modes, on the contrary, are compounded of ſimple ideas of different kinds, as *beauty*, which conſiſts in a certain compoſition of colour and figure, cauſing delight in the beholder: ſuch alſo is *theft*, which is the concealed change of the poſſeſſion of a thing, without the conſent of the proprietor.

Immediate MODES are thoſe immediately attributed to their ſubjects, as motion in a body, knowledge, &c.

Mediate MODES are thoſe attributed to ſubjects by the intervention of ſome other mode, as ſwiftneſs and ſlowneſs, which are attributable to a body, only in reſpect of motion.

Eſſential or *Inſeparable* MODES are attributes without which the ſubſtance cannot ſubſiſt, as wiſdom, &c. in God, &c.

Non-eſſential or *Separable* MODES are attributes affecting created ſubſtances, and affixed thereto as long as is neceſſary, as coldneſs in water, &c.

Poſitive MODES are thoſe which give ſomething poſitive to their ſubſtance, as roundneſs in a globe.

Privative MODES are attributed to ſubjects, when the mind, perceiving ſomething wanting therein, frames a word which at firſt ſight ſeems to note ſomething poſitive, but in reality denotes the want of ſome mode.

MODES *of Spirit* are two, knowledge and willing.

MODES *of Body* are three, figure, reſt, and motion.

MODE, or MOOD *of Syllogiſms*, among logicians. See SYLLOGISM.

MODE, in muſic, the particular order of the concinnous degrees of an octave; the fundamental note whereof may be called the key, as it ſignifies that principal note which regulates the reſt.

The proper difference therefore, between a mode and a key is this, that an octave, with all its natural and concinnous degrees, is called a mode, with reſpect to the conſtitution or manner of dividing it; and, with reſpect to its place in the ſcale, it is called a key. Now it may be farther obſerved, that of the natural notes of every mode, three go under the name of the eſſential notes, namely, the fundamental, the third and fifth; their octaves being reckoned the ſame, and marked with the ſame letters in the ſcale; the reſt are called dependents: again, the fundamental is alſo called the final, the fifth the dominante, and the third, as being between the other two, the mediante.

MODERATOR, in the ſchools, the perſon who preſides at a diſpute, or in a public aſſembly: thus the preſident of the annual aſſembly of the church of Scotland is ſtiled moderator.

MODERATOR-RING, in anatomy, is uſed by Valſalva for that ring which the muſcles of the eye make round the optic nerve at the bottom of the orbit.

MODERN, in a general ſenſe, ſomething new, or of our time, in oppoſition to what is antique or ancient.

MODIFICATION, in philoſophy, that which modifies a thing, or gives it this or that manner of being.

Quantity and quality are accidents which modify all bodies. According to Spinoſa's ſyſtem, all the beings that compoſe the univerſe are only ſo many different modifications of one and the ſame ſubſtance; and it is the different arrangement and ſituation of their parts, that make all the difference between them.

MODILLIONS, in architecture, ornaments in the corniche of the Ionic, Corinthian, and Compoſite columns. See the articles IONIC, CORINTHIAN, and COMPOSITE.

The

The modillions are little inverted conſoles, or brackets, in form of an S under the ſoffit of the corniche, ſeeming to ſupport the projecture of the larmier; though in reality they are no more than ornaments. See plate LXXXIX. *fig.* 1.

They ought always to be placed over the middle of the column. They are particularly affected in the Corinthian order, where they are uſually enriched with ſculpture. Their proportions ought to be ſo adjuſted, as to produce a regularity in the parts of the ſoffits. The intermodillions, i. e. the diſtances between them, depend on the inner columns, which oblige the modillions to be made of a certain length and breadth, in order to render the intervals perfect ſquares, which are always found to have better effects than parallelograms. To this it muſt be added, that in adjuſting the modillions, care ſhould be taken that they have ſuch a proportion as that when the orders are placed over one another, there be the ſame number in the upper order as in the lower, and that they fall perpendicularly over one another.

Modillions are alſo uſed under the corniches of pediments, though Vitruvius obſerves, that they were not allowed in his time, becauſe modillions were intended to repreſent the ends of rafters. Daviler rather takes them for a kind of inverted conſoles, or corbels. The modillion is ſometimes called a mutule, though cuſtom has introduced a little difference between the idea of a modillion and a mutule; the mutule being peculiar to the Doric order, and the modillions to the higher orders. In the Ionic and Compoſite orders, modillions are more ſimple, having ſeldom any ornaments except ſometimes a ſingle leaf underneath. M. Le Clerc obſerves on the Corinthian order, that it is uſual to have a leaf that takes up their whole breadth, and almoſt their whole length too; but he is of opinion, that the modillions would be more graceful, if this leaf was leſs both in length and breadth.

MODIOLUS, in ſurgery, an inſtrument otherwiſe called a trepan. See the article TREPAN.

MODULATION, in muſic, the art of keeping in, or changing the mode or key. See the articles KEY and MODE.

MODULE, in architecture, a certain meaſure or bigneſs, taken at pleaſure, for regulating the proportions of columns, and the ſymmetry, or diſpoſition of the whole building. Architects generally chooſe the ſemi-diameter of the bottom of the column for their module, and this they ſubdivide into parts or minutes. The module of Vignola, which is a ſemi-diameter, is divided into twelve parts in the Tuſcan and Doric, and into eighteen for the other orders. The module of Palladio, Scamozzi, M. Cambray, Deſgodetz, Le Clerc, &c. which is alſo equal to the ſemi-diameter, is divided into thirty parts or minutes in all the orders. The whole height of the column is divided by ſome into twenty parts for the Doric, twenty-two and a half for the Ionic, twenty-five for the Roman, &c. and one of theſe parts is made a module to regulate the reſt of the building by.

There are two ways of determining the meaſures, or proportions of buildings. The firſt is by a fixt ſtandard-meaſure, which is uſually the diameter of the lower part of the column, called a module, ſubdivided into ſixty parts called minutes. In the ſecond there are no minutes, nor any certain or ſtated diviſion of the module, but it is divided occaſionally into as many parts as are judged neceſſary; thus the height of the Attic baſe, which is half the module, is divided either into three, to have the height of the plinth, or into four, for that of the greater torus; or into ſix, for that of the leſſer. Both theſe manners have been practiſed by the ancient as well as the modern architects, but the ſecond, which was that chiefly uſed among the ancients, is, in the opinion of M. Perrault, the preferable. As Vitruvius has leſſened his module in the Doric order, which is the diameter of the lower part of the other orders, and has reduced that great module to a mean one, which is the ſemi-diameter, the module is here reduced to the third part, for the ſame reaſon, viz. to determine the ſeveral meaſures without a fraction. For in the Doric order, beſides that the height of the baſe, as in the other orders, is determined by one of thoſe mean modules, the ſame module gives likewiſe the height of the capital, architrave, triglyphs, and metopes. But our little module, taken from the third of the diameter of the lower part of the column, has uſes much more extenſive; for by this the height of the pedeſtals or columns and entablatures in all the orders are determined without a fraction. As then the great module or diameter of the column has ſixty minutes, and the mean module, or half the diameter, thirty minutes, our little module has twenty.

MOERHINGIA, moſſy chickweed, in botany, a genus of plants, the flower of which is compoſed of four ſhort, undivided petals; and its fruit is a ſubgloboſe capſule, with one cell, in which are contained numerous round ſeeds.

MOHAIR, in commerce, a kind of ſtuff made of ſilk and hair.

MOINEAU, in fortification, is a flat baſtion raiſed between two other baſtions, when a re-entering angle before a curtain is too long. The moineau is commonly joined to the curtain, but it is ſometimes ſeparated from it by a foſs, in which caſe it is called a detached baſtion. The moineau is not raiſed ſo high as the works of the place, becauſe it ought to be expoſed to the fire of the place in caſe the enemy ſhould lodge themſelves in it.

MOISTURE, a term ſometimes uſed to denote animal fluids, the juices of plants, or dampneſs of the air or other bodies. See FLUID, JUICE, &c.

Radical MOISTURE, among phyſicians, ſignifies a vital fluid, which nouriſhes and maintains life, as oil does a lamp. However, Dr. Quincy obſerves, that ſuch a fluid is a mere chimera, unleſs we thereby mean the maſs of blood. See BLOOD.

MOLARES, or DENTES MOLARES, in anatomy, the large teeth, called in Engliſh grinders. See the article TEETH.

MOLE, *Talpa*, in zoology, makes a genus of quadrupeds, of the order of the feræ, thus characteriſed: the feet are formed like hands, and calculated for digging; and it has no external ears.

Of this genus there are two ſpecies: 1. The common mole, a well known little animal, of a bluiſh black colour; very miſchievous to the farmers, by throwing up the ground of their paſtures. 2. The pointed tail-leſs mole, ſomewhat larger than the common kind: it is of a mixed colour, in which a purpliſh and yelloviſh tinge ſeem the prevailing ones. It is a native of Aſia, and lives under ground, like the common mole.

MOLE, *Mola carnea*, in medicine, a maſs of fleſhy matter, of a ſpherical figure, generated in the uterus, or womb, and ſometimes miſtaken for a child. Its ſize is various, from that of a large nut to that of a fœtus. Some moles are ſoft and ſpongy, and others membranous, with a cavity in the middle. Sometimes they are filled with ſerous matter, and ſometimes with hydatides.

The ſymptoms of a mole, at firſt, are like thoſe of a real pregnancy; but afterwards they vary; for the woman feels a dull heavy weight, like that of a ball of lead; her belly being round and ſpherical, without any motion like that of a living fœtus.

The mole itſelf threatens no danger, all the difficulty lying in being delivered of it. Some women are troubled with them for ſeveral years, and others all their life, without any other inconvenience than uneaſineſs and weight.

The cure conſiſts in expelling the mole; for which purpoſe the aſſiſtance of an expert midwife or ſurgeon becomes neceſſary. If the mouth of the uterus ſhould be too ſtrongly contracted to admit the hand of the operator, it is proper to excite the woman's throws by briſk cathartics and ſtrong clyſters; while the os uteri, and parts adjacent, are in the mean time gradually relaxed by the application of emollient fomentations, &c. which done, one or two of the fingers are to be firſt gently inſinuated, and then the whole hand by degrees, in order to extract the mole, as directed for the fœtus. See the article DELIVERY.

If the mole adheres to the uterus, as it frequently does, it is to be gently ſeparated before extraction; and if it be too large to be got out entire, it may be carefully ſeparated and extracted in pieces, either with the fingers, or a falciform hook. To conclude, ſays Heiſter, if a mole does

not occaſion any bad ſymptoms, or uneaſineſs in the mother, and its extraction appears difficult, no violence ſhould be uſed; ſince we have many inſtances of moles retained in the uterus, without any great detriment to the patient, as long as they lived.

MOLE, *Moles*, is alſo a maſſive work of large ſtones laid in the ſea by means of coffer-dams; extending before a port, either to defend the harbour from the impetuoſity of the waves, or to prevent the paſſage of ſhips without leave.

MOLE, *Moles*, in antiquity, a kind of mauſoleum, in form of a round tower, built upon a ſquare baſe.

MOLE, a ſort of harbour, wherein ſhipping may ride ſheltered from the winds and ſeas: it is formed by erecting a mole-head; theſe are not frequent in Great-Britain or Ireland, but are more common in the Mediterranean, as Leghorn-mole, Algiers-mole, Alexandria-mole, &c.

MOLE-HEAD, a ſort of pier, mound, or artificial iſthmus, built athwart the outer-part of a little bay, and joining to ſome head or iſland, to form a retreat for ſhipping.

MOLE-HILLS. — Theſe little hillocks of earth are a very great prejudice to the paſture lands, not only waſting ſo much of the land as they cover, but hindering the ſcythe in mowing. In the weſt of England, they uſe a peculiar inſtrument for the breaking up of theſe; it is a flat board, very thick, and of about eight inches in diameter, into which there is faſtened a perpendicular handle of three or four feet long. It has four broad and ſharp iron teeth at the front, which readily cut through the hill, and ſpread the earth it conſiſts of; and behind there is a very large knob, proper for breaking the clods with, if there are any. Some uſe a ſpade, or other common inſtrument, in the place of this, but not ſo well. There is, however, a much better inſtrument even than this, for deſtroying theſe hills, where they are in very great numbers. This is a kind of horſe machine; it has a ſharp iron about three feet over, and with a ſtrong back. It is about four or five inches broad, and has two long handles for a horſe to be harneſſed to, and a croſs bar of iron to ſtrengthen it at the bottom of the handles, reaching from one handle to the other. The middle of this croſs-bar is furniſhed with one, two, or more, ſharp pieces of iron, like ſmall plough-ſhares, to cut the mole-hills into two, three, or more parts. The iron behind is of a ſemicircular figure. A ſingle horſe is harneſſed to this machine, and a boy muſt be employed to drive it, and a man to hold and guide it; the ſharp irons or ſhares are the firſt thing that meets the hills; they run through it, break its texture, and cut it into ſeveral parts, and the circular iron, following immediately behind them, cuts up the whole by the roots, and leaves the land level. This inſtrument will deſtroy as many mole-hills in one day as a common labourer can in eight, and would be of very great advantage to the kingdom, if brought into general uſe. *Mortimer's Huſbandry.*

MOLLUGO, baſtard-madder, in botany, a plant without any flower-petals: its fruit is a capſule of a ſomewhat oval figure, with three cells; in each of which there are a number of kidney-ſhaped ſeeds.

MOLOSSES, in commerce, the thick fluid matter remaining after the ſugar is made, reſembling ſyrup. See SUGAR.

MOLOSSUS, in Greek and Latin poetry, a foot compoſed of three long ſyllables, as *delectant*.

MOLTING, the change of feathers, hair, or horns, in birds and beaſts. See MEWING.

MOLUCCA-BEANS, *Moluccella*, in botany, a genus of plants, the flower of which is monopetalous and labiated; the upper-lip being entire, and the lower one trifid: the ſeeds are turbinated, and contained in the bottom of the cup.

MOMENT, in the doctrine of time, an inſtant, or the moſt minute and indiviſible part of duration. See TIME.

Strictly ſpeaking, however, a moment ought not to be conſidered as any part of time, but only as the termination or limit thereof.

MOMENT, in the doctrine of infinites, denotes the ſame with infiniteſimal. See INFINITESIMAL.

Leibnitz, and other foreigners, call theſe moments differences. See CALCULUS DIFFERENTIALIS.

MOMENT, *Momentum*, in mechanics, ſignifies the ſame with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter, multiplied into the velocity; or, which is the ſame thing, it may be conſidered as a rectangle under the quantity of matter and velocity. See MOTION.

MOMORDICA, the wild cucumber, in botany, a genus of plants, with a monopetalous flower, divided into five ſegments; the fruit is an apple, burſting open with great elaſticity, and containing a number of compreſſed ſeeds.

This genus comprehends the momordica and luffa of Tournefort, and the elaterium of Boerhaave; and indeed the elaterium of the ſhops, a violent purge, is the fruit of this plant.

MONADELPHIA, in botany, a claſs of plants, the ſixteenth in order, ſo called becauſe the ſtamina of the flowers are ſo interwoven as to form one body; or rather, becauſe the ſtamina are connected, or coaleſce at the baſe. See BOTANY.

MONANDRIA, in botany, a claſs of plants, the firſt in order, with only one ſtamen, or male part, in each flower.

The monandria are ſubdivided into two orders, which are denominated monandria-monogynia, and monandria-digynia, according as they contain one or two ſtyles. See the article STYLE.

MONARCHY, a government in which the ſupreme power is inveſted in a ſingle perſon. There are ſeveral kinds of monarchies, as where the monarch is inveſted with an abſolute power, and is accountable to none but God. It is an error to ſuppoſe, that a deſpotic or abſolute monarch is a ſoleciſm in politics, and that there can be none ſuch legally; for the contrary is true, and that in different parts of the world, and from various principles. In China it is founded on paternal authority, and is the baſis of the government; in Turky, Perſia, Barbary, and India, it is the effect of religion; and in Denmark, the king is legally abſolute by the ſolemn ſurrender which the people made to his predeceſſor of their liberties. Another kind of monarchy is that which is limited, where the ſupreme power is virtually in the laws, though the majeſty of government, and the adminiſtration, is veſted in a ſingle perſon. Monarchies are alſo either hereditary, where the regal power deſcends immediately from the poſſeſſor to the next heir by blood; or elective, where the choice depends upon all who enjoy the benefit of freedom, as in Poland; or upon a few perſons in whom the conſtitution veſts the power of election, as in the German empire. See KING and GOVERNMENT.

MONASTERY, a convent, or houſe built for the reception and entertainment of monks, mendicant friars, or nuns, whether it be an abbey, priory, &c.

Monaſteries are governed by different rules, according to the different regulations preſcribed by their founders. The firſt regular and perfect monaſteries were founded by St. Pachomius in Egypt; but St. Baſil is generally conſidered as the great father and patriarch of the eaſtern monks; ſince in the fourth century he preſcribed rules for the government of the monaſteries, to which the Anachorets and Cœnobites, and the other ancient fathers of the deſarts ſubmitted. In like manner St. Benedict was ſtiled the patriarch of the weſtern monks; he appeared in Italy towards the latter end of the fifth century, and publiſhed his rule, which was univerſally received throughout the Weſt. St. Auguſtine being ſent into England by St. Gregory the pope, in the year 596, to convert the Engliſh, he at the ſame time introduced the monaſtic ſtate into this kingdom, which made ſuch progreſs here, that within the ſpace of two hundred years, there were thirty kings and queens who preferred the religious habit to their crowns, and founded ſtately monaſteries, where they ended their days in ſolitude and retirement.

MONASTIC, ſomething belonging to monks. See MONK.

MONDAY, *Dies Lunæ*, the ſecond day of the week, ſo called as being anciently ſacred to the moon, q. d. moon-day.

MONEY, *Moneta*, a piece of matter, commonly metal, to which public authority has affixed a certain value and weight, to ſerve as a medium in commerce.

The æra of the invention of money is not eaſily to be ſettled. There is no room to doubt but that in the earlieſt ages the ordinary way of traffic among men, was by trucking or exchanging one commodity for another; but in courſe of time it was found neceſſary, in the way of commutative juſtice, to have ſome common meaſure or ſtandard, according to which all things ſhould be eſtimated. See EXCHANGE.

Money is uſually divided into real and imaginary. Real money includes all coins, whether of gold, ſilver, copper, or the like; ſuch as guineas, crowns, piſtoles, pieces of eight, ducats, &c.

Imaginary money, or money of account, is that which has never exiſted, or at leaſt, which does not exiſt in real ſpecie; but is a denomination invented or retained to facilitate the ſtating of accounts, by keeping them ſtill on a fixed footing, not to be changed in current coins, which the authority of the ſovereign ſometimes raiſes or lowers, according to the exigencies of the ſtate, of which kinds are pounds, livres, marks, maravedies, &c.

Engliſh MONEY *of Account* is the pound, ſhilling, and pence; the firſt and laſt being imaginary money, and exchanges calculated in one of them two: the pound contains twenty ſhillings, and the ſhilling twelve pence.

Scotch MONEY *of Account* is the pound, ſhilling, and penny; the pound containing twenty ſhillings, being equivalent to one ſhilling and eight pence Engliſh; and the ſhilling containing twelve pennies, equal to a penny Engliſh. There is alſo among them an account of marks, the mark being equivalent to one ſhilling $1\frac{1}{3}$ penny Engliſh: of this laſt kind they had formerly a ſilver-coin.

French MONEY *of Account* is in livres, ſols, and deniers, of which twelve deniers make a ſol, and twenty ſols a livre: their exchange is by the crown of three livres, or ſixty ſols.

Dutch MONEY *of Account* is kept at Amſterdam and Rotterdam, the two chief trading places, in guilders, ſtivers, and penins; ſo that though goods are ſold for other ſpecie, ſuch as livre de gros, &c. yet all are reduced to the above denominations for the entries into their books. The exchanges are made with us in ſo many ſhillings to a pound ſterling, though in moſt other places in deniers-de-gros.

Spaniſh MONEY *of Account* is at Cadiz kept in rials of plate and its fractions; at Caſtile, in maravedies; at Valencia, in livres or dollars, ſueldos and dineros; of which laſt, twelve make a ſueldo, and twenty ſueldos a livre or dollar. Seventeen quartos at Cadiz and Caſtile make two rials vellon, which is now an imaginary coin, though formerly it was the principal one of the kingdom. A maravedie is another imaginary ſpecie, of which ſeventeen is reckoned to a rial vellon. The ducat is alſo a fictitious coin of eleven rials of plate in purchaſes, ſales, and other mercantile tranſactions, except in exchanges, when it is valued at eleven rials of plate and one maravedie, or 375 maravedies.

Portugueſe MONEY *of Account* is kept in reas, or rés, making a ſeparation at every hundred, thouſandth, &c. 800 reas go to a moidore.

German and Swiſs MONEY *of Account*. At Coningſberg, Elbing, and Dantzick, accounts are kept in rixdollars and gros, or in Poliſh guilders, gros, and deniers, or penins. They exchange on Amſterdam in Poliſh gros for a livre de gros of ſix guilders current money of Amſterdam, and on Hamburg for the rixdollar. At Lubeck, accounts are kept in marks, ſchellings, and deniers or penins-lubs, in which their exchanges are made. At Breſlaw, accounts are kept in rixdollars and ſilver gros and penins; in the firſt of which ſpecies exchanges are made on Amſterdam for a certain number of ſtivers, bank money, and on Hamburg for rixdollars of Breſlaw, againſt rixdollars of Hamburg bank. At Hamburg, accounts are kept in marks, ſchellings, and deniers-lubs bank money, by thoſe who have caſh in the bank; but by thoſe who have not, their books are generally kept in rixdollars, ſchellings, and denier current money. At Bremen, accounts are kept in rixdollars and gros, and it exchanges on Amſterdam rixdollars of ſeventy-two gros, for rixdollars of fifty ſtivers banco. At Leipſic and Naumbourg, accounts are kept in rixdollars, crowns, gros, and penins. At Berlin, and in all this kingdom, accounts are kept in guilders, gros, and penins. At Zurich, accounts are kept in rixdollars, worth about 4s. 6d. ſterling, at 108 of their creutzers. At Frankfort on the Maine, and Hanau, accounts are kept in rixdollars and creutzers. At Vienna, accounts are kept in guilders, creutzers, and penins, reckoning eight penins to a creutzer, and ſixty creutzers to a guilder. At Nuremberg and Augſbourg, accounts are kept in guilders, creutzers, and hellers; at Liege, in livres, ſols, and deniers.

In the canton of St. Gall, in Switzerland, accounts are kept in guilders, creutzers, and penins; or under the ſame denomination with the coins of the empire. In the canton of Baſil, accounts are variouſly kept, ſome in rixdollars, ſchellings, and deniers; ſome in livres, ſchellings, and deniers; ſome in rixdollars, creutzers, and penins; and ſome in guilders, creutzers, and penins.

Italian MONEY *of Account*. In the cities of Genoa and Novi, accounts are kept in livres, ſoldi, and denari; or in dollars of 100 ſoldis. At Milan, accounts are kept in livres, ſoldis, and denari, to be counted like pounds, ſhillings, and pence, viz. twelve denaris to a ſoldi, &c. At Rome, accounts are kept in crowns, julios, and bajoches, or grains and quartrins; the crown is divided into ten julios, and the julio into ten bajoches. At Leghorn, accounts are generally kept in dollars, ſoldi, and denari. At Florence, they keep their books and accounts in crowns, ſoldi, and denari, picoli or current money. At Naples, accounts are kept in ducats, florins, and grains. The accounts in Sicily are kept the ſame as at Naples. At Lucca they keep their accounts in crowns, livres, ſoldi, and denari; the crown is worth 7 livres 10 ſoldi; the livre, 20 ſoldi; and the ſoldi, 12 denari. At Venice, accounts are kept in livres, ſoldi, and denari, picoli or current; but the bank-entries are in livres, ſoldi, and groſſes: both the current and bank-ducats of Venice make 24 ſoldi, or 6 livres and four ſoldi. At Bologna, accounts are kept in livres, ſoldi, and denari; the livre being 20 ſoldi, and the ſoldi 12 denari. At Bergam, the money of account is the ſame as at Bologna, and its proportions the ſame. At Parma accounts are kept in crowns, ſoldi, and denari; the crown is 20 ſoldi, and the ſoldi 20 denari. At Modena and Mantua, accounts are kept in livres, ſoldi, and denari. In Savoy and Piedmont, accounts are kept in livres, or lires, ſoldi, and quartrins. At Placentia, accounts are kept in crowns, ſoldi, and denari of mark; of which 12 denari make a ſoldi, and 20 ſoldi the crown. In the iſland of Sardinia, accounts are kept as in moſt parts of Italy, in livres, ſoldi, and denari. In the iſland of Malta, the money of account is the ſame with that of Sicily. In the iſland of Candia, the account is the ſame as at Venice.

Ruſſian, Swediſh, Daniſh, and Poliſh MONEY *of Account*. In the trading places of the Ruſſian empire, accounts are kept in roubles, grives, and moſcoſques, or in roubles and coppecks; 10 coppecks, each of which is equal to two moſcoſques, make a grive, and 100 coppecks, or 10 grives, is a rouble. In the kingdom of Sweden, accounts are kept in dollars, marks, and oorts; the dollar being worth four marks, and the mark eight oorts. In Denmark, accounts are kept in marks and ſchellings; the rixdollar is worth ſix marks; the mark, 16 ſchellings; and the ſchelling, three penins. Accounts are kept at Bergen, and in other places in Norway, in Daniſh rixdollars, marks, and ſchellings. In Poland, accounts are kept in guilders, gros, and deniers, of which 18 deniers make a gros, and 30 gros a guilder: they here keep accounts alſo in rixdollars and gros, reckoning 90 of the latter to one of the former. At Riga, accounts are kept in rixdollars and gros, the former of which ſpecies conſiſts of 90 of the latter.

Turkiſh MONEY *of Account*. The Turks, both in Europe, Aſia, and Africa, account by purſes, either of ſilver or gold, the laſt being only uſed in the ſeraglio, with half purſes of gold, called alſo rizes: the purſe of ſilver is equal to 1500 French livres, or about 65 l. ſterling; and the half purſe in proportion: the purſe of gold is 15000 ſequins, equal to 30000 French crowns, or about 3750 l. ſterling: this is ſeldom uſed but for preſents to favourites, ſo that a purſe ſimply ſignifies a purſe of ſilver, or 1500 livres. The merchants alſo uſe Dutch dollars, called aſtani or abouquels, with medins and aſpers: the dollar

dollar is equal to 35 medins, and the medin to three aſpers; the aſper to a halfpenny ſterling money.

Aſiatic MONEYS *of Account* are as follow. In Perſia they account by the taman, called alſo man and tumein, and dinar-biſti; the taman is compoſed of 50 abaſſis, or 100 mamodies, or 200 chapes, or 10000 dinars; which, accounting the abaſſi on the foot of 18 French ſols, or the dinar on that of a denier, amounts to 3l. 12s. 6d. ſterling the taman. They alſo account by larins, eſpecially at Ormus, and on the coaſt of the Perſian gulph: the larin is equivalent to 11 d. ſterling; and on that footing is uſed alſo in Arabia, and through a great part of the Eaſt-Indies.

Chineſe MONEYS *of Account* are the pic, picol, and tael; which, though in effect weights, do likewiſe ſerve as money of account, obtaining in Tonquin as well as China: the pic is divided into 100 catis, ſome ſay 125; the cati into 16 taels, each tael equal to one ounce two drachms: the picol contains 66 ⅔ caties; the tael is equivalent to 6s. 8 d. ſterling.

Japoneſe MONEYS *of Account* are the ſchuites, cockiens, oebans or oubans, and taels: 200 ſchuites are equal to 500 Dutch pounds, the cockien equal to 10 Low-country pounds, 1000 oebans make 45000 taels.

Mogul MONEY *of Account*. At Surat, Agra, and the reſt of the eſtates of the great mogul, they uſe lacres, acrees, or leeths, implying one hundred thouſand; thus a lacre of rupees is 100,000 rupees; the lacre being nearly on the footing of the tun in Holland, and the million of France.

MONEYS *of Account* of other iſlands and coaſts of India. Throughout Malabar, and at Goa, they uſe tangas, vintins, and pardos-xeraphin; the tanga is of two kinds, viz. of good and bad alloy; hence their cuſtom is to count by good or bad money; the tanga of good alloy is better by one fifth than the bad, ſo that four tangas good being allowed the pardos-xeraphin, there will be required five of the bad; four vintins good make a tanga likewiſe good; fifteen barucos, a vintin; a good baruco is equal to a Portugueſe ree, a French denier, or one thirteenth of a penny ſterling. In the iſland of Java they uſe the ſonta, ſapacou, fardos, and catis; which laſt money, together with the leeth or lacre, is much uſed throughout all the Eaſt-Indies; the ſonta is 200 caxas, or little pieces of that country, hung on a ſtring, and is equal to eleven twelfths of a penny ſterling; five ſontas make the ſapacou. The fardos equal to 2 s. 8 d. ſterling; the cati contains 20 taels; the tael 6 s. 8 d. ſterling. There are iſlands, cities, and ſtates of the Eaſt-Indies, whoſe monies of account are not here expreſſed, partly becauſe reducible to ſome of the above-mentioned, and partly becauſe we find no certain conſiſtent account of them.

African MONEY *of Account*. From Cape Verd to the Cape of Good-Hope, all exchanges and valuations of merchandize are made on the foot of the macoute and piece; which, though no monies of account, for thoſe barbarians have no real monies, and therefore need imaginary ones to eſtimate them by, yet ſerve in lieu thereof. At Loango de Boirie, and other places on the coaſt of Angola, the eſtimations are made by macoutes; and at Malimbo and Cabindo, on the ſame coaſt, the negroes reckon by pieces: among the firſt the macoute is equal to 10 pieces; ten macoutes make 100, which likewiſe gives us a kind of imaginary money to eſtimate any purchaſe, exchange, &c. they fix on the one ſide the number of macoutes required; e. gr. for a negro; ſo that there are ſeveral bargains made for one; ſuppoſe, for inſtance, the ſlave to be fixed at 3500 pieces, this amounts to 350 macoutes in merchandize, they fix the price of each in macoutes. Two Flemiſh knives, e. gr. are accounted one macoute; a copper-baſon, 2 ℔ weight, three; a barrel of gunpowder, three, &c. For the piece, it ſerves in like manner to eſtimate the value of goods, duties, &c. on either ſide: thus the natives require ten pieces for a ſlave; and the Europeans put, for inſtance, a fuſee at one piece, a piece of ſalampours at four pieces, &c. The cities of Barbary and Egypt, whither the Europeans traffic, reckon much after the ſame manner as in the Levant, and the dominions of the grand ſignior; for the reſt, through that vaſt extent of coaſt where we trade for negroes, gold-duſt, elephants teeth, wax, leather, &c. either the inhabitants do not know what money of account is, or, if they have any, it is only what ſtrangers, ſettled among them, have introduced.

MONEYERS, MONEYORS, or MONIERS, officers of the mint, who work and coin gold and ſilver money, and anſwer all waſte and charges.

MONITORY LETTERS are letters of warning and admonition, ſent from an eccleſiaſtical judge, upon information of ſcandals and abuſes, within the cognizance of his court.

MONK, a perſon who wholly dedicates himſelf to the ſervice of religion, in ſome monaſtery, under the direction of ſome particular ſtatutes and rules.

The moſt probable account of the original of the monks is, that in the Decian perſecution, in the middle of the third century, many perſons in Egypt, to avoid the fury of the ſtorm, fled to the neighbouring deſarts and mountains, where they not only found a ſafe retreat, but alſo more time and liberty to exerciſe themſelves in acts of piety and divine contemplations; which ſort of life became ſo agreeable, that when the perſecution was over, they refuſed to return to their habitations again, chooſing rather to continue in thoſe cottages and cells, which they had made for themſelves in the wilderneſs. From that time to the reign of Conſtantine, monachiſm was confined to the hermits or anachorets, who lived in private cells in the wilderneſs; but when Pachomius had erected monaſteries, other countries preſently followed the example.

MONKEY, *Simia*, in zoology, a numerous genus of quadrupeds of the order of the anthropomorpha, or quadrupeds that reſemble the human figure: their face is naked; the claws are rounded and flattiſh, in ſome degree like the nails on the human hand; and they have both an upper and lower eye-lid.

Of all the animals of the monkey-kind, the ſatyr reſembles mankind moſt; its face is naked, and is very like that of an aged and not handſome man; it has no tail, and in other reſpects greatly reſembles the human form. The moſt like, next to this, is the oran-outang, or black-faced monkey, called the ſavage; and the next to this is the baboon, or whiſkered-ſimia, with a ſhort tail: the reſt of the monkeys, of which there are a great many kinds, differing widely both in ſize and figure, have nevertheleſs ſomething of the human aſpect; and as they are tractable animals, people make them walk erect with a ſtaff, and perform many tricks, to ſhew their reſemblance; but, in general, ſuch monkeys as have no tails, have more of this likeneſs than thoſe that have.

MONOCHORD, a muſical inſtrument, compoſed of one ſtring, uſed to try the variety and proportion of ſounds.

MONODY, in ancient poetry, a mournful kind of ſong, ſung by a perſon all alone, to give vent to his grief.

MONOECIA, in botany, one of Linnæus's claſſes of plants, the twenty-firſt in order; in which the male and female flowers are placed ſeparately on the ſame plant, or rather on different ſtalks growing from the ſame root.

Of the plants belonging to this claſs, ſome have only one ſtamen, and others have three, four, five, ſix, or more ſtamina; whence the ſubordinate orders of monoecia-monandria, monoecia-triandria, &c. others again are monadelphous, others ſyngeneſious, and others gynandrous.

MONOGRAM, a character or cypher, compoſed of one, two, or more letters, interwoven; being a kind of abbreviation of a name, anciently uſed as a ſeal, badge, arms, &c.

MONOLOGUE, a dramatic ſcene, in which a perſon appears alone on the ſtage, and ſpeaks to himſelf.

The word is derived from the Greek, μονος, alone, and λογος, diſcourſe.

MONOMIAL, in algebra, a root or quantity, that has only one name or member, as ab, aab, &c.

A monomial may be either rational or irrational.

MONOPETALOUS, in botany, is applied to flowers that have only one undivided leaf.

The word is derived from the Greek μονος, alone, and πεταλον, a leaf.

MONOPOLY, in commerce, denotes when a perſon makes himſelf ſole maſter of a commodity, manufacture, &c. in order to enhance the price thereof.

The word is derived from the Greek μονος, alone, and πωλεω, to ſell.

There are two kinds of monopoly, when a perſon buys up corn, &c. to retail it again at an advanced price; or when a patent is procured, prohibiting any other perſon to ſell a certain commodity but the patentee.

MONOPTERE, in architecture, a kind of temple, round, and without walls, having a dome ſupported by columns.

MONOPTOTON, in grammar, a noun that has only one caſe, as *inficias*.

MONOPYRENEOUS, in botany, ſuch fruit as contains only one ſeed or kernel.

MONORHYME, a piece of poetry, in which all the verſes end with the ſame rhyme.

MONOSTICH, an epigram that conſiſts of only one ſingle verſe.

MONOSYLLABLE, in grammar, a word that conſiſts of only one ſyllable, and is compoſed of either one or more letters pronounced at the ſame time.

MONOTHELITES, a ſect of Chriſtians in the ſeventh century, ſo called from their maintaining that, though there were two natures in Jeſus Chriſt, the human and divine, there was but one will, which was the divine.

MONOTONY, an uniformity of ſound, or a fault in pronunciation, when a long ſeries of words are delivered in one unvaried tone.

MONSOON, in phyſiology, a ſpecies of trade-wind, in the Eaſt-Indies, which for ſix months blows conſtantly the ſame way, and the contrary way the other ſix months. See WIND.

MONTH, *Menſis*, in chronology, the twelfth part of a year. See YEAR.

Time being duration, marked out for certain uſes, and meaſured by the motion of the heavenly bodies, there thence reſults divers kinds of months as well as years, different from one another, according to the particular luminary by whoſe revolution they are determined, and the particular purpoſes they are deſtined for; hence months are of two kinds, aſtronomical and civil.

An aſtronomical month is that which is governed either by the motion of the ſun or moon, and is conſequently of two kinds, ſolar and lunar: a ſolar month is that time, in which the ſun ſeems to run through a whole ſign, or the twelfth part of the ecliptic.

Hence, if regard be had to the ſun's true apparent motion, the ſolar month will be unequal, ſince the ſun is longer in paſſing through the winter-ſigns than through thoſe of the ſummer; but as he conſtantly travels through all the twelve ſigns in 365 days, 5 hours, and 49 minutes, the quantity of a mean month will be had, by dividing that number by 12; on this principle, the quantity of a ſolar month will be found to be 30 days, 10 hours, 29 minutes, 5 ſeconds. See EARTH.

A lunar month is that ſpace of time which the moon takes up in performing its courſe through the zodiac, or that meaſured by the motion of the moon round the earth; and is of three kinds, viz. periodical, ſynodical, and that of illumination. The lunar periodical month is the ſpace of time wherein the moon makes her round through the zodiac, or wherein ſhe returns to the ſame point, being 27 days, 7 hours, 43 minutes, 5 ſeconds. See MOON.

The lunar ſynodical month, called alſo abſolutely the lunar month and lunation, is the ſpace of time between two conjunctions of the moon with the ſun; or the time it takes from one conjunction with the ſun to the next; or from one new moon to another: the quantity of a ſynodical month is 29 days, 12 hours, 44 minutes, 3 ſeconds, and 11 thirds. The quantity of a ſynodical month is not the ſame at all times, for in the ſummer ſolſtice, when the ſun ſeems to move ſloweſt, the ſynodical month appeareth leſs, being about 29 days, 6 hours, 42 minutes; but in the winter, when the ſun's motion ſeems faſter, the moon does not fetch up the ſun ſo ſoon, for which reaſon the ſynodical month then ſeems greater, viz. 29 days, 19 hours, and 37 minutes, according to the obſervation of the ſame aſtronomers: ſo that the firſt quantity given of the ſynodical month, is to be underſtood as to the mean motion. From what has been ſaid, it may eaſily appear that the difference between a periodical and ſynodical month is this; the firſt is called periodical in reſpect of the moon's orbit: but the ſynodical is ſo called in reſpect of its connection with the other luminary. Now after the time of its conjunction, the ſun does not continue in the ſame place of the zodiac, but moves forwards towards the eaſt; upon which it falls out that the moon, finiſhing its courſe, does not find the ſun again in the ſame place where it left him, he being removed almoſt a whole ſign from his former place; ſo that to overtake the ſun again, it plainly appears that a certain ſpace of time is requiſite beſides the periodical, which makes up the ſynodical month.

The ancient Romans made uſe of the lunar months, and made them alternately of 29 and 30 days; and they marked the days of each month by three terms, viz. calends, nones, and ides.

The lunar month of illumination, or appoſition, or illuminative month, is the ſpace from the firſt time of the moon's appearance after new moon, to her firſt appearance after the new moon following. The lunar month of illumination is not of any determined quantity, becauſe the moon appears ſometimes ſooner, and ſometimes later, after the conjunction; for which diverſity aſtronomers give us ſeveral reaſons, particularly the obliquity of the zodiac, the variable latitude of the moon, the apparent inequality of its motion, the different qualities of the ſummer and winter-air, &c. By this month, however, the Turks and Arabs go; and it is ſaid that the ancient Britons went by the phaſes of the moon.

A civil or political month conſiſts of a certain number of days, according to the laws and cuſtoms of the different countries wherein it is uſed, either having no regard to the ſolar or lunar months, as thoſe of the Egyptians in their equal year, of the Romans in the year of Romulus, &c. or coming pretty near to the ſolar aſtronomical month, as the Julian; or elſe the lunar aſtronomical, as the Jewiſh, Turkiſh, and others. The Britiſh and moſt European nations make twelve months in the year, viz. January, February, &c. See the articles JANUARY, &c.

Civil ſolar months are ſuch civil months as are accommodated to the aſtronomical months, or thoſe which are to conſiſt alternately of 30 and 31 days, excepting one month of the twelve, which, for every fourth year, conſiſted of 30 days, and for the other years of 29. This form of civil months was introduced by Julius Cæſar; but under Auguſtus the ſixth month, till then, from its place, called Sextilis, was denominated Auguſtus, in honour of that prince; and to make the compliment yet the greater, a day was added to it, ſo that it now conſiſts of 31 days, though till then it had only 30; to make up for which, a day was taken from February, ſo that from thenceforward it only conſiſted of 28 days, and every fourth year of 29; though before it had ordinarily conſiſted of 29 days, &c. and ſuch are the civil or calendar months which now obtain throughout Europe.

Civil lunar months are to conſiſt alternately of 29 and 30 days: thus will two civil months be equal to two aſtronomical ones, abating for the odd minutes, and conſequently the new moon will be hereby kept to the firſt day of each ſuch civil month, for a long time together. However, to make them keep conſtantly pace with the civil months, at the end of each 948 months, a month of 29 days muſt be added, or elſe every 33d month muſt conſiſt of 30 days. This was the month in civil or common uſe among the Jews, Greeks, and Romans, till the time of Julius Cæſar.

MONTPAGNOTE, or POST *of the Invulnerable*, in the military art, an eminence choſen out of the reach of the cannon of a place beſieged, where curious perſons poſt themſelves, to ſee an attack, and the manner of the ſiege, without being expoſed to any danger.

MONUMENT, in architecture, a building deſtined to preſerve the memory, &c. of the perſon who raiſed it, or for whom it was raiſed; ſuch are a triumphal arch, a mauſoleum, a pyramid, &c.

MONYCHA, among naturaliſts, an appellation given to animals with ſingle or undivided hoofs.

MOOD, or MODE, in logic, called alſo ſyllogiſtic mood, a proper diſpoſition of the ſeveral propoſitions of a ſyllogiſm, in reſpect of quantity and quality.

As in all the ſeveral diſpoſitions of the middle term, the propoſitions of which a ſyllogiſm conſiſts, may be either univerſal or particular, affirmative or negative; the due determination of theſe, and putting them together, as the laws of argumentation require, conſtitute what logicians call the moods of ſyllogiſms. Of theſe moods there are a determinate number to every figure, including all the poſſible ways in which propoſitions, differing in quantity or quality, can be combined, according to any diſpoſition of the middle term, in order to arrive at a juſt concluſion. There are two kinds of moods, the one direct, the other indirect.

The direct mood is that wherein the concluſion is drawn from the premiſes directly and immediately, as, "Every animal is a living thing, every man is a living animal; therefore, every man is a living thing." There are fourteen of theſe direct moods, four of which belong to the firſt figure, four to the ſecond, and ſix to the third. They are denoted by ſo many artificial words framed for that purpoſe, viz 1 Barbara, celarent, darii, ferioque. 4 Baralip, celantes, dabitis, fapeſino, friſeſom. 2 Ceſare, cameſtres, feſtino, baroco. 3 Darapti, felapton, diſamis, datiſi, bocardo, feriſon. The uſe and effect of which words lie wholly in the ſyllables, and the letters of which the ſyllables conſiſt; each word, for inſtance, conſiſts of three ſyllables, denoting the three propoſitions of a ſyllogiſm, viz. major, minor, and concluſion; add, that the letters of each ſyllable are either vowels or conſonants; the vowels are A, which denotes an univerſal affirmative; E, an univerſal negative; I, a particular affirmative; and O, a particular negative: thus Barbara is a ſyllogiſm or mood of the firſt figure, conſiſting of three univerſal affirmative propoſitions: Baralip, one of the fourth figure, conſiſting of two univerſal affirmative premiſes, and a particular affirmative concluſion. The conſonants are chiefly of uſe in the reduction of ſyllogiſms. See the articles FIGURE and REDUCTION.

The indirect mood is that wherein the concluſion is not inferred immediately from the premiſes, but follows from them by means of a converſion; as, "Every animal is a living thing, every man is an animal; therefore ſome living thing is a man."

MOOD, or MODE, in grammar, the different manner of conjugating verbs, ſerving to denote the different affections of the mind. See VERB.

Hence ariſe four moods, viz. the indicative, ſubjunctive, and imperative: of thoſe the three firſt are called finite moods, becauſe they define a certain perſon and number; but the fourth is called the infinite, becauſe in it there is no diſtinction of either perſon or number. See INDICATIVE, &c.

Some grammarians reckon five moods, viz. the indicative, ſubjunctive, optative, imperative, and infinitive; and ſome make ſix, dividing the optative into potential and optative. See the articles OPTATIVE and POTENTIAL.

MOON, *Luna*, ☽, in aſtronomy, a ſatellite, or ſecondary planet, always attendant on our earth.

Of the ſix primary planets, we find but three that are certainly attended with moons, viz. the earth, Jupiter, and Saturn; for though Mr. Short has given an account of a phænomenon that he obſerved ſome years ago, which ſeems extremely like a moon about Venus, yet, as it was never obſerved before nor ſince through the beſt of teleſcopes, it does not appear to be a moon: however, that the reader may uſe his own judgment, we refer him to the account given of it in the Philoſophical Tranſactions.

The diſtance of our moon from the earth is determined by her horizontal parallax, or the angle which the ſemidiameter of the earth ſubtends at the moon, viz. the angle AOC (plate LXXXIX. *fig.* 2) which is the difference between the true place of the moon's center O, when in the horizon, and the apparent place thereof, as viewed from the ſurface of the earth at A. The former is known by aſtronomical tables, the latter by obſervation: and the quantity of this difference or angle at a mean is $57' 12'' = AOC$.

If therefore we ſay, As the tangent of $57' 12''$ is to radius, ſo is $AC = 1$ to $CO = 60,1$; this will be the mean diſtance of the moon in ſemidiameters of the earth. Therefore, ſince one ſemidiameter of the earth contains 3982 miles, we have $3982 \times 60,1 = 239318,2 = CO$ the mean diſtance of the moon.

The moon's apparent ſemidiameter MO meaſures (at her mean diſtance) $15' 38'' = 938''$ by the micrometer, which is the quantity of the angle MCO. The earth's diameter therefore is to the moon's as $3432''$ to $938''$, that is, as 109 to 30, or as 3,63 to 1. Wherefore $\frac{30}{109} \times 7964 = 2192$ miles the moon's diameter.

Therefore the face of the earth, as it appears to the lunarians, is to the face of the moon, as it appears to us, as 109×109 to 30×30, viz. as 11881 to 900, or as 13,2 to 1. And the real bulk of the earth is to that of the moon as $109 \times 109 \times 109$ to $30 \times 30 \times 30$, viz. as 1295029 to 27000, that is, as 1295 to 27, or as 48 to 1 very nearly.

Sir Iſaac Newton mentions the atmoſphere about the moon, but other aſtronomers think there is reaſon (not to ſay a demonſtration) for the contrary: for, were there an atmoſphere of air like ours, it muſt neceſſarily obſcure the fixed ſtars in the moon's appulſe to them; but it has been obſerved that this never happens; on the contrary, they preſerve all their ſplendor to the moment of their occultation, and then diſappear inſtantaneouſly, and in the ſame manner they recover their light, when they appear again on the other ſide. And this I am very certain of from a remarkable occultation of Jupiter, which I obſerved with a good reflecting teleſcope from the beginning to the end with all the attention poſſible, becauſe I was very deſirous to be ſatisfied about that matter; and all the phænomena conſpired to convince me, there was nothing like an atmoſphere about the moon.

That the ſurface of the moon is not ſmooth or even, but diverſified with hills and vales, continents and ſeas, lakes, &c. any one would imagine who views her face through a large teleſcope. That ſhe has variety of hills and mountains is demonſtrable from the line which bounds the light and dark parts not being an even regular curve, as it would be upon a ſmooth ſpherical ſurface, but an irregular broken line, full of dents and notches, as repreſented in *fig.* 3. Alſo becauſe many ſmall (and ſome large) bright ſpots appear in the dark portion, ſtanding out at ſeveral ſmall diſtances from the boundary line; which ſpots in a few hours become larger, and at laſt unite with the enlightened portion of the diſk.

On the other hand, we obſerve many ſmall ſpots interſperſed all over the bright part, ſome of which have their dark ſides next the ſun, and their oppoſite ſides very bright and circular, which infallibly proves them to be deep, hollow, round cavities; of which there are two very remarkable ones near together on the upper part, and may be viewed exceeding plain, when the moon is about four or five days old.

To meaſure the height of a lunar mountain is a curious problem, and at the ſame time very eaſy to effect in the following manner. Let C (plate LXXXIX. *fig.* 4.) be the moon's center, EDB a ray of the ſun touching the moon's ſurface in D, and the top of a mountain in B. Draw CB and CD; the height of the mountain AB is to be found. With a micrometer in a teleſcope find what proportion the diſtance of the top of the mountain B, from the circle of illumination at D, bears to the diameter of the moon, that is, the proportion of the line DB to DF; and, becauſe DF is known in miles, DB will be alſo known in that meaſure.

Now admit that DB : DC :: 1 : 8, as in one of the hills it will be; then becauſe AC or DC the ſemidiameter of the moon is known to be 1096 miles, DB will be $\frac{1096}{8}$ or 137 miles; therefore the hypothenuſe BC will be found equal to 1104.5, from which ſubtract the radius AC, there remains 8.5 the height AB nearly. This mountain then, being $8\frac{1}{2}$ miles high, is near three times higher than the higheſt mountain on the earth.

Again, the cavities are proportionably large and deep. I have obſerved cavities in the moon more than the 100th part

part of the moon's diameter in breadth, which is about 200 miles upon the moon's ſurface; their depths appear likewiſe proportional. The lunar cavities therefore prodigiouſly exceed the height of the mountains; and conſequently the ſurface of the moon has but little ſimilitude to the ſurface of the earth in theſe reſpects.

Since the moon's ſurface appears to be ſo very mountainous and irregular, it has been a queſtion, how it comes to paſs that the bright circular limb of the diſk does not appear jagged and irregular, as well as the curve bounding the light and dark parts? In anſwer to this, it muſt be conſidered that, if the ſurface of the moon had but one row of mountains placed round the limb of the diſk, the ſaid bright limb would then appear irregularly indented; but ſince the ſurface is all over mountainous, and ſince the viſible limb is to be conſidered not as a ſingle curve line, but a large zone, having many mountains lying one behind another from the obſerver's eye, it is evident the mountains in ſome rows, being oppoſite to the vales in others, will fill up the inequalities in the viſible limb in the remoter parts, which diminiſh to the ſight and blend with each other, ſo as to conſtitute (like the waves of the ſea) one uniform and even horizon.

Whether there be ſeas, lakes, &c. in the moon, has been a queſtion long debated, but now concluded in the negative: for in thoſe large darker regions, which were thought to be ſeas, we view through a good teleſcope many permanent bright ſpots, as alſo caverns and empty pits, whoſe ſhadows fall within them, which can never be ſeen in ſeas or any liquid ſubſtance. Their dark and duſky colour may proceed from a kind of matter or ſoil which reflects light leſs than that of the other regions.

Theſe ſpots in the moon have continued always the ſame unchangeably, ſince they were firſt viewed with a teleſcope; though leſs alterations than what happen in the earth in every ſeaſon of the year, by verdure, ſnow, inundations, and the like, would have cauſed a change in their appearance. But, indeed, as there are no ſeas nor rivers in the moon, and no atmoſphere, ſo of courſe there can be no clouds, rain, ſnow, or other meteors, whence ſuch changes might be expected.

The aſtronomers have drawn the face of the moon, according as it is ſeen with the beſt teleſcopes; for which we are obliged to the accurate labours of the famous ſelenographers Florentius, Langrenus, John Hevelius of Dantzic, Grimaldus and Ricciolus, Italians; who have taken particular care to note all the ſhining parts of the moon's face, and, for the better diſtinguiſhing them, they have given to each part a proper name. Langrenus and Ricciolus have divided the lunar regions among the philoſophers and aſtronomers, and other eminent men: but Hevelius, fearing leſt the philoſophers ſhould quarrel about the diviſion of the lands, has ſpoiled them of this their property, and given the parts of the moon thoſe geographical names, that belong to the different iſlands, countries, and ſeas of our earth, without any regard to their ſituation or figure. See *fig.* 5.

Since, as we have ſhewn, the mean diſtance of the moon is about 60 ſemidiameters of the earth, at the diſtance of the moon one degree of the earth's ſurface will ſubtend an angle of one minute, and will therefore be viſible; but ſuch a deg. is equal to 69 ½ miles; therefore a ſpot or place 70 miles in diameter in the moon will be juſt viſible to the naked eye. Hence a teleſcope that magnifies about 100 times will juſt diſcover a ſpot whoſe diameter is $\frac{1}{100}$ of 70 miles, or $\frac{7}{10}$ of a mile, or 3698 feet: and a teleſcope that will magnify 1000 times will ſhew an object that is but $\frac{1}{1000}$ of a mile, that is, whoſe diameter is but 370 feet, or little more than 120 yards; and therefore will eaſily ſhew a ſmall town or village, or even a gentleman's ſeat, if any ſuch there be.

The time which the moon takes up in making one revolution about the earth, from a fixed ſtar to the ſame again, is 27 d. 7 h. 43′, which is called the periodical month. But the time that paſſes between two conjunctions, that is, from one new moon to another, is equal to 29 d. 12 h. 44′ 3″, which is called a ſynodical month: For, after one revolution is finiſhed, the moon has a ſmall arch to deſcribe to get between the ſun and the earth, becauſe the ſun keeps advancing forwards in the ecliptic. Now this ſurplus of motion takes up 2 d. 5 h. 1′ 3″, which added to the periodical month makes the ſynodical, according to the mean motions.

The moon moves about its own axis in the ſame time that it moves about the earth, from whence it comes to paſs that ſhe always ſhews the ſame face to us: for by this motion about her axis juſt ſo much of her ſurface is turned towards us conſtantly, as by her motion about the earth would be turned from us.

But ſince this motion about the axis is equable and uniform, and that about the earth, or common center of gravity, is unequal and irregular, as being performed in an ellipſis, it muſt follow, that the ſame part of the moon's ſurface preciſely can never be ſhewn conſtantly to the earth; and this is confirmed by the teleſcope, through which we often obſerve a little gore or ſegment on the eaſtern and weſtern limb appear and diſappear by turns, as if her body librated to and fro; which therefore occaſioned this phænomenon to be called the moon's libration.

The orbit of the moon is elliptical, more ſo than any of the planets, and is perpetually changing or variable, both in reſpect of its figure and ſituation; of which we ſhall treat more largely further on. The inclination of the moon's orbit to the plane of the ecliptic is alſo variable, from 5 degrees to 5° 18′. The line of nodes likewiſe has a variable motion from eaſt to weſt, contrary to the order of the ſigns, and compleats an entire revolution in a ſpace of time a little leſs than 19 years. Alſo the line of the apſides, or of the apogee and perigee, has a direct motion from weſt to eaſt, and finiſhes a revolution in the ſpace of about nine years. All which will be more copiouſly treated of when we come to explain the phyſical cauſes thereof.

The phaſes of the moon in every part of the orbit are eaſily accounted for from her different ſituation with reſpect to the earth and ſun: for though to an eye placed in the ſun ſhe will always exhibit a compleat illuminated hemiſphere, yet in reſpect to the earth, where that hemiſphere is viewed in all degrees of obliquity, it will appear in every degree from the greateſt to the leaſt; ſo that at E (*fig.* 6.) no part at all of the enlightened ſurface can be ſeen. At F a little part of it is turned towards the earth, and from its figure it is then ſaid to be horned. At G one half of the enlightened ſurface is turned to the earth, and ſhe is then ſaid to be dichotomiſed, and in her firſt quarter or quadrature. At H a part more than half is turned to the earth, and then ſhe is ſaid to be gibbous. At A her whole illuminated hemiſphere is ſeen, being then in oppoſition to the ſun; and this is called the full moon. At B ſhe is again gibbous, but on the other part; at C ſhe is again dichotomiſed, and in her laſt quarter; at D ſhe is horned, as before; and then becomes new again at E, where ſhe is in conjunction with the ſun.

If MN (*fig.* 7.) be drawn perpendicular to the line SL joining the centers of the ſun and moon, and OP perpendicular to the line TL joining the centers of the earth and moon, it is evident the angle OLM in the firſt half of the orbit, and PLN in the ſecond, will be proportional to the quantity of the illuminated diſk turned towards the earth; and this angle is every-where equal to the angle ETL, which is called the elongation of the moon from the ſun.

To find what quantity of the moon's viſible ſurface is illuſtrated for any given time, we are to conſider that the circle of illumination BFC (*fig.* 8.) is oblique to the view every-where (but at quarter and full), and therefore by the laws of the orthographic projection (which ſee under the article *Orthographic* PROJECTION) it will be projected into an ellipſe whoſe longeſt axis is the diameter of the moon BC, and the ſemi-conjugate is FL = coſine of the angle of elongation FBP. Hence FP = verſed ſine of the ſaid angle. But from the nature of the circle and ellipſe we have LP in a conſtant ratio to FP, wherever the line PO is drawn perpendicular to B; therefore alſo 2 LP = PO has a conſtant ratio to FP. But (by Euclid V. 12.) the ſum of all the lines OP = area of the circle is to the ſum of all the lines FP = area of the illuminated part, as the diameter of the circle OP to the verſed ſine of the elongation FP.

As the moon illuminates the earth by a reflex light, ſo does

does the earth the moon; but the other phænomena will be different for the moſt part. We ſhall inſert them for the reader's curioſity as follows. (1.) The earth will appear but to little more than one half of the lunar inhabitants. (2.) To thoſe to whom the earth is viſible, it appears fixed, or at leaſt to have no circular motion, but only that which reſults from the moon's libration. (3.) Thoſe who live in the middle of the moon's viſible hemiſphere ſee the earth directly over their heads. (4.) To thoſe who live in the extremity of that hemiſphere the earth ſeems always nearly in the horizon, but not exactly there, by reaſon of the libration. (5.) The earth in the courſe of a month would have all the ſame phaſes as the moon has. Thus the lunarians, when the moon is at E (*fig.* 9.) in the middle of their night, ſee the earth at full, or ſhining with a full face; at G it is dichotomiſed, or half light and half dark; at A it is wholly dark, or new; and at the parts between theſe it is gibbous. (6.) The earth appears variegated with ſpots of different magnitudes and colours, ariſing from the continents, iſlands, oceans, ſeas, clouds, &c. (7.) Theſe ſpots will appear conſtantly revolving about the earth's axis, by which the lunarians will determine the earth's diurnal rotation, in the ſame manner as we do that of the ſun.

To find the Age, or change of the MOON.

Janus 0, 2, 1, 2, 3, 4, 5, 6,
8, 8, 10, 10, theſe to the epact fix,
The ſum, bate 30, to the month's day add,
Or take from 30, age, or change, is had.

EXAMPLE. March 10, 1752.

Ep. = 14
1 = N° of the month.
15
10 = day of the month.
25 days = moon's age.

30
15
15 March = change.

To find the Time of the MOON's *coming to the South, and of High-Water at* London-Bridge.

Four times the moon's age, if by 5 you divide,
Gives the hour of her ſouthing; add 2 for the tide.

EXAMPLE. Moon's age = 9 days.

4
5) 36 (7 H.
1
12 M. = $\frac{1}{5}$ H.

7 H. 12 M. p. m. = ſouthing.
2
9 12 = high water.

To find the Time of the MOON's *beginning to ſhine.*—Multiply her age, if under 15, by 48, and divide the product by 60; the quotient gives the hour, and the remainder the minute. If her age be above 15 days, ſubtract the time thus found from 24; the remainder gives the time of ſhining in the morning.

The great Sir Iſaac Newton's *Theory of the* MOON.—By this theory what by all aſtronomers was thought moſt difficult and almoſt impoſſible to be done, the excellent Sir Iſaac Newton hath effected; viz. to determine the moon's place even in her quadratures and all other parts of her orbit, beſides the ſyzygies, ſo accurately by calculation, that the difference between that and her true place in the heavens ſhall ſcarce be two minutes, and is uſually ſo ſmall, that it may well enough be reckoned only as a defect in the obſervation. And this Sir Iſaac Newton experienced by comparing it with very many places of the moon, obſerved by Mr. Flamſteed, and communicated to him.

The royal obſervatory at Greenwich is to the weſt of the meridian of Paris 2 degrees 19 minutes. Of Uraniburgh 12 degrees, 51 minutes, 30 ſeconds. And of Dantzic 18 degrees, 48 minutes.

The mean motions or places of the ſun and moon accounted from the vernal equinox, at the meridian of Greenwich, I make to be as followeth.

The laſt day of December 1680, at noon (old ſtile) the mean motion or place of the ſun was 9 ſigns, 20 degrees, 34 minutes, 46 ſeconds. Of the ſun's apogee, was 3 ſigns, 7 degrees, 23 minutes, 30 ſeconds.

The mean motion or place of the moon at that time was 6 ſigns, 1 degree, 45 minutes, 45 ſeconds. And of her apogee, 8 ſigns, 4 degrees, 28 minutes, 5 ſeconds. Of the aſcending node of the moon's orbit, 5 ſigns, 24 degrees, 14 minutes, 35 ſeconds, &c.

And on the laſt of December 1700, at noon, the mean motion or place of the ſun was 9 ſigns, 20 degrees, 43 minutes, 50 ſeconds. Of the ſun's apogee, 3 ſigns, 7 degrees, 44 minutes, 30 ſeconds. The mean motion or place of the moon was 10 ſigns, 15 degrees, 19 minutes, 50 ſeconds. Of the moon's apogee, 11 ſigns, 8 degrees, 18 minutes, 20 ſeconds. And of her aſcending node, 4 ſigns, 27 degrees, 24 minutes, 20 ſeconds. For in 20 Julian years, or 7305 days, the ſun's motion is 20 revolutions, 0 ſigns, 0 degs. 9 minutes, 4 ſeconds; and the motion of the ſun's apogee 21 minutes, 0 ſeconds. The motion of the moon in the ſame time is 267 revolutions, 4 ſigns, 13 degrees, 34 minutes, 5 ſeconds; and the motion of the lunar apogee, is 2 revolutions, 3 ſigns, 3 degrees, 50 minutes, 15 ſeconds; and the motion of her node, 1 revolution, 0 ſigns, 26 degrees, 50 minutes, 15 ſeconds.

All which motions are accounted from the vernal equinox: wherefore if from each except the laſt (to which the motion of 16′ 40″ muſt be added becauſe the lunar nodes move in antecedentia) there be ſubtracted the receſſion or motion of the equinoctial point, in antecedentia, during that ſpace, which is 16 minutes, 40 ſeconds, there will remain the motions in reference to the fixed ſtars in 20 Julian years, viz. the ſun's 19 revolutions, 11 ſigns, 29 degrees, 52 minutes, 24 ſeconds. Of his apogee, 4 minutes, 20 ſeconds. And the moon's 267 revolutions, 4 ſigns, 13 degrees, 17 minutes, 25 ſeconds. Of her apogee, 2 revolutions, 3 ſigns, 3 degrees, 33 minutes, 35 ſeconds. And of the node of the moon, 1 revolution, 0 ſigns, 27 degrees, 6 minutes, 55 ſeconds.

According to this computation the tropical year is 365 days, 5 hours, 48 minutes, 57 ſeconds. And the ſydereal year is 365 days, 6 hours, 9 minutes, 14 ſeconds.

Theſe mean motions of the luminaries are affected with various inequalities, of which there are the annual equations of the aforeſaid mean motions of the ſun and moon, and of the apogee and node of the moon.

The annual equation of the mean motion of the ſun depends on the excentricity of the earth's orbit round the ſun, which is 16 $\frac{1}{2}$ of ſuch parts, as that the earth's mean diſtance from the ſun ſhall be 1000: whence it is called the equation of the center; and is, when greateſt, 1 degree, 56 minutes, 20 ſeconds.

The greateſt annual equation of the moon's mean motion is 11 degrees, 49 ſeconds; of her apogee, 20 minutes; and of her node 9 minutes, 30 ſeconds.

And theſe four annual equations are always mutually proportional one to another, wherefore, when any of them is at the greateſt, the other three will alſo be greateſt; and when any one leſſens, the other three will alſo be diminiſhed in the ſame ratio.

The annual equation of the ſun's center being given, the three other correſponding annual equations will be alſo given; and therefore a table of that will ſerve for all. For if the annual equation of the ſun's center be taken from thence, for any time, and be called P, and let $\frac{1}{15}$ P = Q, Q + $\frac{1}{65}$ Q = R, $\frac{1}{6}$ P = D, D + $\frac{1}{30}$ D = E, and D − $\frac{1}{60}$ D = 2 F; then ſhall the annual equation of the moon's mean motion for that time be R, that of the apogee of the moon will be E, and that of the node F.

Only obſerve here, that, if the equation of the ſun's center be required to be added, then the equation of the moon's mean motion muſt be ſubtracted, that of her apogee muſt be added, and that of her node ſubducted. And on the contrary, if the equation of the ſun's center were to be ſubducted, the moon's equation muſt be added, the equation of her apogee ſubducted, and that of her node added.

Facing Moon.

5 JA 59

There is alſo an equation of the moon's mean motion depending on the ſituation of her apogee, in reſpect of the ſun; which is greateſt when the moon's apogee is in an octant with the ſun, and is nothing at all when it is in the quadratures or ſyzygies. This equation, when greateſt and the ſun in perigæo, is 3 minutes, 56 ſeconds. But, if the ſun be in apogæo, it will never be above 3 minutes, 34 ſeconds. At other diſtances of the ſun from the earth, this greateſt equation is reciprocally as the cube of ſuch diſtance. But, when the moon's apogee is out of the octants, this equation grows leſs, and is to the greateſt equation (ſuppoſing the diſtance of the ſun from the earth to remain the ſame) as the ſine of the double diſtance of the moon's apogee from the next quadrature or ſyzygy to the radius.

This is to be added to the moon's motion, while her apogee paſſes from a quadrature with the ſun to a ſyzygy; but this is to be ſubtracted from it, while the apogee moves from the ſyzygy to the quadrature.

There is moreover another equation of the moon's motion which depends on the aſpect of the nodes of the moon's orbit with the ſun: and this is greateſt when her nodes are in octants to the ſun, and vaniſhes quite, when they come to their quadratures or ſyzygies. This equation is proportional to the ſine of the double diſtance of the node from the next ſyzygy, or quadrature, and at greateſt is but 47 ſeconds. This muſt be added to the moon's mean motion, while the nodes are paſſing from their ſyzygies with the ſun to their quadratures with him; but ſubtracted, while they paſs from the quadratures to the ſyzygies.

From the ſun's true place take the equated mean motion of the lunar apogee, as was above ſhewed, the remainder will be the annual argument of the ſaid apogee. From hence the excentricity of the moon and the ſecond equation of her apogee may be computed after the manner following (which takes place alſo in the computation of any other intermediate equations).

Let T (*fig.* 10.) repreſent the earth, T S a right line joining the earth and ſun, T A C B a right line drawn from the earth to the middle or mean place of the moon's apogee, equated as above: let the angle S T A be the annual argument of the aforeſaid apogee, T A the leaſt excentricity of the moon's orbit, T B the greateſt; biſſect A B in C, and on the center C, with the diſtance A C, deſcribe a circle A F B, and make the angle B C F = to the double of the annual argument. Draw the right line T F; that ſhall be the excentricity of the moon's orbit; and the angle B T F is the ſecond equation of the moon's apogee required.

In order to whoſe determination, let the mean diſtance of the earth from the moon, or the ſemidiameter of the moon's orbit, be 1000000; then ſhall its greateſt excentricity T A be 66782 ſuch parts; and the leaſt T A, 43319. So that the greateſt equation of the orbit, viz. when the apogee is in the ſyzygies, will be 7 degrees, 39 minutes, 30 ſeconds, or perhaps 7 degrees, 40 minutes (for I ſuſpect there will be ſome alteration according to the poſition of the apogee in Cancer or Capricorn). But, when it is in quadrature to the ſun, the greateſt equation aforeſaid will be 4 degrees, 57 minutes, 56 ſeconds; and the greateſt equation of the apogee 12 degrees, 15 minutes, 4 ſeconds.

Having from theſe principles made a table of the equation of the moon's apogee, and of the excentricities of her orbit to each degree of the annual argument, from whence the excentricity T F and the angle B T F (viz. the ſecond and principal equation of the apogee) may eaſily be had for any time required; let the equation thus found be added to the firſt equated place of the moon's apogee, if the annual argument be leſs than 90 degrees or greater than 180 degrees, and leſs than 270, otherwiſe it muſt be ſubducted from it; and the ſum or difference ſhall be the place of the lunar apogee ſecondarily equated; which being taken from the moon's place equated a third time ſhall leave the mean anomaly of the moon correſponding to any given time. Moreover from the mean anomaly of the moon, and before found excentricity of her orbit, may be found (by means of a table of equations of the moon's center made to every degree of the mean anomaly, and ſome excentricities, viz. 45000, 50000, 55000, 60000, and 65000) the proſtaphæreſis or equation of the moon's center, as in the common way: and this being taken from the former ſemicircle of the middle anomaly, and added in the latter to the moon's place thus thrice equated, will produce the place of the moon a fourth time equated.

The greateſt variation of the moon (viz. that which happens when the moon is in an octant with the ſun) is nearly reciprocally as the cube of the diſtance of the ſun from the earth; let that be taken 37 minutes, 25 ſeconds, when the ſun is in perigæo, and 33 minutes, 40 ſeconds, when he is in apogæo: and let the differences of this variation in the octants be made reciprocally as the cubes of the diſtances of the ſun from the earth; and ſo let a table be made of the aforeſaid variation of the moon in her octants (or its logarithms) to every 10th, 6th, or 5th diſtance of the mean anomaly: and for the variation out of the octants, make, as radius to the ſine of the double diſtance of the moon from the next ſyzygy or quadrature :: ſo let the aforeſaid variation in the octant be to the variation congruous to any other aſpect; and this added to the moon's place before found in the firſt and third quadrant (accounting from the ſun) or ſubducted from it in the ſecond and fourth, will give the moon's place equated a fifth time.

Again, as radius to the ſine of the ſum of the diſtances of the moon from the ſun, and of her apogee from the ſun's apogee (or the ſine of the exceſs of that ſum above 360 degrees) :: ſo is 2 minutes, 10 ſeconds, to a 6th equation of the moon's place, which muſt be ſubtracted, if the aforeſaid ſum or exceſs be leſs than a ſemicircle, but added, if it be greater. Let it be made alſo, as radius to the ſine of the moon's diſtance from the ſun :: ſo 2 degrees, 20 ſeconds, to a ſeventh equation: which, when the moon's light is increaſing, ſubtract, but when decreaſing, add; and the moon's place will be equated a ſeventh time, and this is her place in her proper orbit.

Note here, the equation, thus produced by the mean quantity 2 degrees, 20 ſeconds, is not always of the ſame magnitude, but is increaſed and diminiſhed according to the poſition of the lunar apogee. For if the moon's apogee be in conjunction with the ſun's, the beforeſaid equation is about 54 ſeconds greater. But when the apogees are in oppoſition, it is about as much leſs; and it librates between its greateſt quantity 3 minutes, 14 ſeconds, and its leaſt 1 minute, 26 ſeconds. And this is when the lunar apogee is in conjunction or oppoſition with the ſun's: but in the quadratures the aforeſaid equation is to be leſſened about 50 ſeconds, or 1 minute, when the apogees of the ſun and moon are in conjunction; but, if they are in oppoſition, for want of a ſufficient number of obſervations, I cannot determine whether it is to be leſſened or increaſed. And, even as to the augment or decrement of the equation 2 minutes, 20 ſeconds, abovementioned, I dare determine nothing certain, for the ſame reaſon, viz. the want of obſervations accurately made.

If the 6th and 7th equations are augmented or diminiſhed in a reciprocal ratio of the diſtance of the moon from the earth, i. e. in a direct ratio of the moon's horizontal parallax, they will become more accurate: and this may readily be done, if tables are firſt made to each minute of the ſaid parallax, and to every 6th or 5th degree of the augment of the 6th equation for the 6th, as of the diſtance of the moon from the ſun for the 7th equation.

From the ſun's place take the mean motion of the moon's aſcending node, equated as above; the remainder ſhall be the annual augment of the node, whence its ſecond equation may be computed after the following manner in the foregoing figure.

Let T, as before, repreſent the earth; T S a right line conjoining the earth and ſun: let alſo the line T A C B be drawn to the place of the aforeſaid node of the moon as above equated; and let S T A be the annual argument of the node. Take T A from a ſcale, and let it be to A B :: as 56 to 3, or as 11⅔ to 1. Then biſſect A B in C, and on C as a center, with the diſtance C A, deſcribe a circle as A F B, and make the angle B C F, equal to double the annual argument of the node before found: ſo ſhall the angle B T F be the ſecond equation of the aſcending node: which muſt be added when the node is paſſing from the

quadrature to a ſyzygy with the ſun, and ſubducted when the node moves from a ſyzygy towards a quadrature. By which means the true place of the node of the lunar orbit will be gained: whence, from tables made after the common way, the moon's latitude and the reduction of her orbit to the ecliptic may be computed, ſuppoſing the inclination of the moon's orbit to the ecliptic to be 4 degrees, 59 minutes, 35 ſeconds, when the nodes are in quadrature with the ſun; and 5 degrees, 17 minutes, 20 ſeconds, when they are in the ſyzygies.

And from the longitude and latitude thus found, and the given obliquity of the ecliptic 23 degrees, 29 minutes, the right aſcenſion and declination of the moon will be found.

The horizontal parallax of the moon when ſhe is in the ſyzygies at a mean diſtance from the earth, I make to be 57 minutes, 30 ſeconds; and her horary motion 33 minutes, 32 ſeconds, 32 thirds; and her apparent diameter 31 minutes, 30 ſeconds. But in her quadratures at a mean diſtance from the earth I make the horizontal parallax of the moon to be 59 minutes, 40 ſeconds; her horary motion 32 minutes, 12 ſeconds, 2 thirds; and her apparent diameter, 31 minutes, 3 ſeconds; the moon in an octant to the ſun and at a mean diſtance hath her center diſtant from the center of the earth about 60 $\frac{2}{3}$ of the earth's ſemidiameters.

The ſun's horizontal parallax I make to be 10 ſeconds, and its apparent diameter, at a mean diſtance from the earth, I make 32 minutes, 15 ſeconds.

The atmoſphere of the earth, by diſperſing and refracting the ſun's light, caſts a ſhadow as it were upon an opake body at leaſt to the height of 40 or 50 geographical miles. This ſhadow, falling upon the moon in a lunar eclipſe, makes the earth's ſhadow larger or broader. And to each mile of the earth's atmoſphere is correſpondent a ſecond in the moon's diſk, ſo that the ſemidiameter of the earth's ſhadow, projected upon the diſk of the moon, is to be increaſed about 50 ſeconds. Or, which is all one in a lunar eclipſe, the horizontal parallax of the moon is to be increaſed in the ratio of about 70 to 69.

Thus far the theory of this incomparable mathematician. And, if we had many places of the moon accurately obſerved, eſpecially about her quadratures; and theſe well compared with her places at the ſame time calculated according to this theory; it would then appear whether there yet remain any other ſenſible equations, which, when accounted for, might ſerve to improve and enlarge this theory. *Gregory's Aſtron.*

MOOR, in country affairs, denotes an unlimited tract of land, uſually over-run with heath. See GOUTY-LAND and HEATH.

MOOR-BUZZARD, the Engliſh name of the yellow legged falcon, with an iron-coloured body and yellow head. It is about the ſize of a common crow, and has its Engliſh name from building its neſt in mooriſh and boggy places.

MOOR-COCK, or GOR-COCK, a ſpecies of tretrao, with a forked tail, ſpotted with white underneath. It is a native of England, but very rare; the male is throughout of a very deep iron-grey, without any variegation; and the female is alſo grey, but variegated with tranſverſe lines of black.

MOOR-HEN, the Engliſh name of the gallinula or tringa. See TRINGA.

MOORING, in the marine, the act of faſtening a ſhip by two or more cables, in a road, haven, or river.

A ſhip may be either moored in a harbour, head and ſtern; that is, faſtened at both ends with cables, reaching from the fore and hind-parts, or with two cables from one end, viz. one from each bow; or ſhe may be ſecured by moorings, which always remain ſunk in the bottom for that purpoſe.

Moorings are compoſed of anchors, chains, and bridles. The anchors formed for this purpoſe have only one flook, and are ſunk on the two ſides of the river with a ſtrong chain faſtened to each of them, which reaches acroſs the ſtream. In the middle of this chain is fixed a ſwivel or large link, which turns round in the chain as the ſhip ſwings with the tide; and to this link the bridles are faſtened. The bridles are ſhort pieces of cable, whoſe upper ends are drawn into the ſhip at the mooring ports, and afterwards faſtened to the maſts.

MOOR-STONE, a valuable ſtone, much uſed in the coarſer works of the preſent builders; being truly a white granite, of a marbly texture.

MOOT, a difficult caſe argued by the young barriſters and ſtudents at the inns of Court, by way of exerciſe, the better to qualify them for practice, and to defend the cauſes of their clients. This, which is called mooting, is the chief exerciſe of the inns of Court. Particular times are appointed for the arguing moot-caſes: the place where this exerciſe is performed, was anciently called Moot-hall; and there is a bailiff, or ſurveyor of the moots annually choſen by the bench, to appoint the moot-men for the inns of Chancery, and to keep an account of the performance of exerciſes.

MORAL, ſomething belonging to manners, or the conduct of life. See the article GOOD, EVIL, MANNERS, &c.

MORAL PHILOSOPHY, the ſame with ethics. See ETHICS.

MORAL SENSE, that whereby we perceive what is good, virtuous, and beautiful in actions, manners, and characters.

MORALITY, the ſcience and doctrine of morals, otherwiſe called ethics. See ETHICS.

Morality may be defined to be the relation, conformity, or agreement of men's voluntary actions to a rule, to which they are referred, and by which they are judged of. Theſe moral rules ſeem to be of three ſorts, with their different enforcements. 1. The divine, whether known by the light of nature or the voice of revelation, which is the only true touchſtone of moral rectitude, the conſciences of men bearing witneſs either of the goodneſs or ſinfulneſs of their actions; that is, whether as duties or ſins they are like to procure them happineſs, or miſery, from the hands of the Almighty. 2. The civil law, which is the rule ſet by the commonwealth to the actions of thoſe that belong to it: this rule no body overlooks, the rewards and puniſhments being ready at hand to enforce it, extending to the protecting or taking away of the life, liberty, and eſtate of thoſe who obſerve and diſobey it. 3. The law of opinion and reputation, whereby virtue and praiſe, vice and blame are ever found to accompany each other: now thoſe who think not commendation and diſgrace ſufficient motives to engage mankind to accommodate themſelves to the opinions and rules of thoſe with whom they converſe, ſeem little ſkilled in the hiſtory of mankind, ſince moſt people govern themſelves chiefly by this law of faſhion. See the article RELATION.

Moral philoſophy contemplates human nature, its moral powers and connections, and from theſe deduces the laws of action; though it muſt be confeſſed, that different philoſophers have eſtabliſhed different ſyſtems concerning the foundation of morality, which the reader will find under the article ETHICS.

According to Mr. Locke, the idea of a Supreme Being, infinite in power, goodneſs, and wiſdom, whoſe workmanſhip we are, and on whom we depend, and the idea of ourſelves, as intelligent creatures, would, if duly conſidered, afford ſuch foundations of our duty and rules of action, as might place morality among the ſciences capable of demonſtration.

As to the reaſons why the mathematical ſciences have been thought more capable of demonſtration than the ideas of good and evil, right and wrong, &c. they are theſe. 1. That the former can be repreſented by ſenſible marks, as diagrams, which have a nearer correſpondence with them than any words. 2. Moral ideas are commonly more complex than thoſe of figures; whence it happens, that their names are of more uncertain ſignification; and beſides, the mind cannot eaſily retain theſe preciſe combinations ſo perfectly, as is neceſſary in the examination of the agreements and diſagreements of ſeveral of them one with another. See the article KNOWLEDGE.

One part of theſe diſadvantages in moral ideas, continues the ſame great author, may in a good meaſure be remedied by accurate definitions, ſetting down that collection of ſimple ideas which every term ſhall ſtand for

and then uſing the term ſteadily for that preciſe collection. See DEFINITION.

MORASS, a low, moiſt land, which receives the waters from the higher grounds, without having any deſcent to carry them off. See MARSH.

MORATUR, or DEMORATUR, in law, he demurs; a term uſed when one of the parties in a cauſe demurs, and does not proceed in pleading, but reſts upon the judgment of the court in ſome particular point, either in relation to the ſufficiency of the declaration, or the pleas of the contrary party; upon which the court, after taking ſome time to argue and adviſe, determine the point.

MORBID, among phyſicians, ſignifies diſeaſed or corrupt, a term applied either to an unſound conſtitution, or to thoſe parts or humours that are infected by a diſeaſe. See DISEASE.

MORBILLI, the meaſles, in medicine. See the article MEASLES.

MORESK, or MORISCO, is a kind of painting, carving, &c. done after the manner of the Moors; conſiſting of ſeveral groteſque pieces and compartiments, promiſcuouſly mingled, not containing any perfect figure of a man, or other animal; but a wild reſemblance of birds, beaſts, trees, &c.

MORNING, the beginning of the day, the firſt appearance of light, or the time from midnight till noon.

MOROCCO, the capital of the kingdom of the ſame name in Africa, ſituated in the ninth degree of weſt longitude; and in the thirty-ſecond degree of north latitude.

MOROCCO, *Marroquin*, in commerce, a fine kind of leather, prepared of the ſkin of an animal of the goat kind, and imported from the Levant, Barbary, &c.

The name was probably taken from the kingdom of Morocco, whence the manner of preparing it was borrowed, which is this: the ſkins being firſt dried in the hair, are ſteeped in clear water three days and nights; then ſtretched on a tanner's horſe, beaten with a large knife, and ſteeped afreſh in water every day, till they be well come; then they are thrown into a large vat in the ground full of water where quick-lime has been ſlaked, and there lie fifteen days; whence they are taken, and again returned every night and morning. Then they are thrown into a freſh vat of lime and water, and ſhifted night and morning for fifteen days longer; then rinſed in clear water, and the hair taken off on the leg with the knife, returned into a third vat and ſhifted as before for eighteen days; ſteeped twelve hours in a river, taken out, rinſed, put in pails, where they are pounded with wooden peſtles, changing the water twice; then laid on the horſe, and the fleſh taken off; returned into pails of new water, taken out, and the hair ſide ſcraped; returned into freſh pails, taken out, and thrown into a pail of a particular form, having holes at bottom: here they are beaten for the ſpace of an hour, and freſh water poured on from time to time; then being ſtretched on the leg, and ſcraped on either ſide, they are returned into pails of freſh water, taken out, ſtretched and ſewed up all around in manner of bags, leaving out the hinder legs as an aperture for the conveyance of a certain mixture.

The ſkins thus ſerved are put in luke-warm water where dogs excrements have been diſſolved. Here they are ſtirred with long poles for half an hour, left at reſt a dozen, taken out, rinſed in freſh water, and filled by a tunnel with a preparation of water and ſumac, mixed and heated over the fire till ready to boil; and, as they are filled, the hind legs are ſewed up to ſtop the paſſage. In this ſtate they are let down into the veſſel of water and ſumac, and kept ſtirring for four hours ſucceſſively; taken out and heaped on one another; after a little time their ſides are changed; and thus they continue an hour and a half, till drained. This done, they are looſened, and filled a ſecond time with the ſame preparation, ſewed up again, and kept ſtirring two hours, piled up and drained as before. This proceſs is again repeated, with this difference, that they are now ſtirred only a quarter of an hour; after which they are left till next morning, when they are taken out, drained on a rack, unſewed, the ſumac taken out, folded in two from head to tail, the hair-ſide outwards, laid over each other on the leg, to perfect their draining, ſtretched out and dried; then trampled under foot by two and two, ſtretched on a wooden table, what fleſh and ſumac remains ſcraped off, the hair-ſide rubbed over with oil, and that again with water.

Then they are wrung with the hands, ſtretched, and preſſed tight on the table with an iron inſtrument like that of a currier, the fleſh-ſide uppermoſt; then turned, and the hair-ſide rubbed ſtrongly over with a handful of ruſhes, to ſqueeze out as much of the oil remaining as poſſible. The firſt courſe of black is now laid on the hair-ſide, by means of a lock of hair twiſted and ſteeped in a kind of black dye, prepared of ſour beer, wherein pieces of old ruſty iron have been thrown. When half dried by hanging in the air, they are ſtretched on a table, rubbed over every way with a paumelle, or wooden-toothed inſtrument, to raiſe the grain, over which is paſt a light couche of water, then ſleeked by rubbing them with ruſhes prepared for the purpoſe. Thus ſleeked, they have a ſecond couche of black, then dried, laid on the table, rubbed over with a paumelle of cork, to raiſe the grain again; and, after a light couche of water, ſleeked over anew; and to raiſe the grain a third time, a paumelle of wood is uſed.

After the hair-ſide has received all its preparations, the fleſh-ſide is pared with a ſharp knife for the purpoſe; the hair-ſide is ſtrongly rubbed over with a woollen cap, having before given it a gloſs with barberries, citron, or orange. The whole is finiſhed by raiſing the grain lightly, for the laſt time, with the paumelle of cork; ſo that they are now fit for the market.

Manner of preparing Red MOROCCO.—After ſteeping, ſtretching, ſcraping, beating, and rinſing, as before, they are at length wrung, ſtretched on the leg, and paſſed after each other into water where alum has been diſſolved. Thus alumed, they are left to drain till morning, then wrung out, pulled on the leg, and folded from head to tail, the fleſh inwards.

In this ſtate they receive their firſt dye, by paſſing them after one another into a red liquor, prepared with laque, and ſome other ingredients, which the marroquineers keep a ſecret. This they repeat again and again, till the ſkins have got their firſt colour; then they are rinſed in clear water, ſtretched on the leg, and left to drain twelve hours; thrown into water, into which white galls pulverized have been paſt through a ſieve, and ſtirred inceſſantly for a day with long poles; taken out, hung on a bar acroſs the water all night, white againſt red, and red againſt white, and in the morning the water ſtirred up, and the ſkins returned into it for twenty-four hours.

MORPHEW, a leprous kind of ſcurf, which ſometimes breaks out upon the ſkin, particularly about the forehead. See LEPROSY.

MORSE, in zoology, a name by which ſome call the hippopotamus. See HIPPOPOTAMUS.

MORTALITY, or *Bills of* MORTALITY, properly denote weekly liſts of the perſons who die in any place.

In London, theſe bills are drawn up by the company of pariſh-clerks, and contain an account of the numbers, ages, diſeaſes, &c. of ſuch as die within the bills of mortality; that is, in London, Weſtminſter, and ten miles round.

The great diſparity between the births and burials in London, is owing to this, that the diſſenters of all ſorts baptize their children without ſending an account of them to the pariſh clerks; ſo that little dependance is to be had on theſe, with regard to calculating annuities for life. See INTEREST.

MORTAR, a preparation of lime and ſand, mixed up with water, which ſerves as a cement, and is uſed by maſons and brick-layers in building of walls of ſtone and brick.

Beſides the common mortar uſed in laying ſtones, bricks, &c. there are ſeveral other kinds; as, 1. white mortar, uſed in plaſtering walls and ceilings, which are often firſt plaſtered with loam, and is made of ox or cow-hair mixed and tempered with lime and water without any ſand. The common allowance is one buſhel of hair to ſix of lime; the hair binds the mortar, holds it faſt together, and keeps it from cracking. 2. Mortar for furnaces, &c. is made with red clay wrought in water in which horſe-

horſe-dung and chimney ſoot has been ſteeped, by which a ſalt is communicated to the water, which binds the clay and makes it fit to endure the fire: this clay ought not to be too fat, leſt it ſhould be ſubject to crack; nor too lean or ſandy, leſt it ſhould not bind enough. 3. Some workmen in metals, uſe a kind of mortar to plaſter over the inſide of the veſſels in which they refine their metals, to keep them from running out: this kind of mortar is made with quick-lime and ox-blood, the lime being firſt beaten to powder and ſifted, and afterwards mixed with the blood. 4. Mortar for ſun-dials on walls, may be made of lime and ſand tempered with linſeed-oil, or, for want of the latter, with ſkimmed milk; but oil is better. This ſpread upon the wall will become as hard as ſtone, and will endure the weather ſix times as long as the ordinary plaſter made of lime and hair with water. 5. For plaſtering the fronts of houſes in imitation of brick-work, ſome uſe a mortar made of ſharp ſand and lime, powder of brick, and ſome red ochre: and timber-houſes, plaſtered over with this kind of mortar, look well though they have been done twenty or thirty years. 6. The mortar uſed in Italy for making water courſes and ciſterns, and alſo in finiſhing or plaſtering of fronts is of two ſorts: the one is compoſed of lime and hogs-greaſe, mixt with the juice of figs, and the other is of the ſame ingredients, but has liquid pitch added to the reſt, and is firſt wet or ſlaked with wine, and then pounded or beaten with hogs-greaſe and juice of figs. 7. An extraordinary good mortar for floors, walls, ceilings, &c. may be made with ox-blood and fine clay tempered together. 8. And in buildings, one part of waſte ſoap aſhes, mixed with another of lime and ſand, make a very durable mortar.

MORTAR-PIECE, a ſhort piece of ordnance, conſiderably thick and wide; ſerving to throw bombs, carcaſſes, fire-pots, &c. See plate XC. *fig.* 1. which repreſents a mortar mounted on its carriage.

The uſe of mortars is thought to be older than that of cannon; they being employed in the wars in Italy to throw ſtones and balls of red-hot iron, long before the invention of bombs; which, as Blondel informs us, were firſt thrown at the ſiege of Wachtendonck, in Guelderland, in 1588.

It was formerly the opinion of gunners, that only one certain charge of powder was requiſite for each mortar, and that the horizontal range could not be altered but by changing the direction of the piece; but, at preſent, when a place lying in the ſame horizontal plane with the mortar, is to be bombarded, they elevate the piece to 45°, and augment or diminiſh the charge of powder until they can hit the mark. The following advantages introduced this practice: 1. The public powder is ſaved as much as poſſible; becauſe, at a direction of 45°, a leſs velocity, and conſequently a leſs charge of powder is required to make any horizontal range, than is neceſſary to make the ſame horizontal range at any other elevation. 2. In elevating mortars to their proper directions, gunners ſeldom come within a degree or two of the propoſed elevation, both on account of the imperfection of the inſtruments which they generally uſe for that purpoſe, and the hurry they are in at that time. And in bombarding towns from ſhips, it is ſcarce poſſible to come within two degrees of the deſigned elevation, becauſe of the agitation of the veſſel, which continually changes the direction of the mortar. But by raiſing the mortar to 45°, the bad conſequences of this inaccuracy of elevation are in a great meaſure prevented, becauſe a ſmall error above or below 45°, occaſions a very inconſiderable error of amplitude.

For the ſame reaſons, alſo, places lying above or below the horizontal plane, paſſing through the piece, are bombarded by directing the mortar ſo as its axis may biſſect the angle comprehended between a perpendicular to the horizon, at the point of projection, and a line drawn from that point to the mark aimed at; and then augmenting and diminiſhing the charge of powder until the object be hit.

When the buſineſs, therefore, can be effectually done by this middle elevation, it ought certainly to be preferred to any other.

In ſhooting with mortars, the following general rules ſhould be always obſerved. 1. To meaſure the diſtance of the object aimed at. 2. That the bombs be of equal weight, otherwiſe the ſhots will vary. 3. That the carriage be on an exact level, to prevent its leaping. 4. That the powder with which the piece is charged, be always of the ſame ſtrength and quantity. 5. That the charge be always equally rammed down. 6. That the wads be always of wood, tompions, or oakum. 7. That the fuſees be freſh made the days on which they are to be uſed; and that they be of a compoſition proportionable to the range of the ſhot in the air, ſo that the bomb may break at the very moment of, or ſoon after, its fall; which compoſition muſt be ſuch as not to be extinguiſhed though it fall in water, but continue burning till the bomb breaks. See BOMB.

MORTGAGE, in law, a pledge or pawn of lands, tenements, &c. for money borrowed; ſo called becauſe if the money is not paid at the day, the land dies to the debtor, and is forfeited to the creditor. The common method of making a mortgage, is by leaſe for a long term of years, wherein a pepper-corn rent has been uſually reſerved; or it may be made by aſſignment for a term, and by leaſe and releaſe. The creditor, who holds the eſtate according to the condition of the deed, is called the mortgagee; but the mortgager, who is the perſon that makes the mortgage, generally keeps poſſeſſion of the land till failure is made in the payment of the mortgage money; in which caſe, though the mortgagee enters for non-payment, the mortgager has a right to the equity of redemption in the court of chancery, where he may call the mortgagee to an account for the profits of the land mortgaged.

By a late ſtatute it is ordained, that when any action of ejectment is brought by a mortgagee, for the recovery of the poſſeſſion of the lands or tenements, &c. mortgaged, and there is no ſuit in equity for foreclоſing or redeeming the equity of redemption, in caſe the perſon intitled to redeem ſhall, *pendente lite*, or pending the action, bring all the principal and intereſt due, with coſts, into court, it ſhall be taken as a full ſatisfaction and diſcharge of the mortgage, and the mortgagee ſhall thereon be obliged to reconvey the land, &c. and deliver up all deeds, &c. 7 Geo. 2. c. 201.

MORTIFICATION, in medicine, the ſame with ſphacelus. See the article SPHACELUS.

MORTISE, or MORTOISE, in carpentry, &c. a kind of joint, wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, in law, is the alienation of lands or tenements to any religious houſe, corporation, or fraternity, and their ſucceſſors. Lands alienated in mortmain are different from others, for they never revert to the donor, or to any temporal or common uſe; on which accounts the lords by ſuch alienation loſe their eſcheats, and many ſervices that were formerly due to them; as bodies politic never die, nor can perform perſonal ſervice, commit treaſon, felony, or the like. By the ſtatute of mortmain lately made, it is enacted, that no manors, lands, &c. ſhall be given or granted to, or ſettled upon any perſons, bodies politic, &c. for any eſtate whatſoever, or charged in truſt for charitable uſes, unleſs it be done by deed indented and ſealed twelve months at leaſt before the donor's death, and inrolled in chancery within ſix months after executed. The two Univerſities, and the colleges of Eaton, Weſtminſter, &c. are excepted out of this act. 9 Geo. II. c. 36.

MORTUARY, in the eccleſiaſtical law, is a gift left by a man at his death to his pariſh-church, in recompence of perſonal tythes omitted to be paid in his life-time: or it is that beaſt, or other cattle, which after the death of the owner, by the cuſtom of the place, is due to the parſon or vicar, in lieu of tithes or offerings forgot, or not well and truly paid by him that is dead.

MOSAIC, or MOSAIC-WORK, an aſſemblage of little pieces of glaſs, marble, precious ſtones, &c. of various colours, cut ſquare, and cemented on a ground of ſtucco, in ſuch a manner as to imitate the colours and degradations of painting.

The materials uſed for theſe works are little pieces of glaſs of all the different ſhades in every tint or colour, like thoſe of the fine Engliſh worſted uſed in needle-work. They

5 JA 59

The glaſs is firſt caſt into thin cakes, which are afterwards cut into long pieces of a different thickneſs. Many of the pieces uſed in the works on roofs and cielings, which are conſequently ſeen only at a great diſtance, appear to be a finger's breadth; but the finer works conſiſt only of glaſs pins, if we may make uſe of that expreſſion, not thicker than a common ſewing needle, ſo that a portrait of four feet ſquare ſhall take up two millions of ſuch pins or ſtuds.

Theſe pins are ſo cloſely joined together, that after the piece is poliſhed, which is done in the ſame manner as looking-glaſſes are poliſhed, it can hardly be diſcerned to be an arrangement of an infinite number of particles of glaſs; but rather looks like a picture painted with the fineſt colours, with cryſtal placed before it. The ground in which theſe vitreous pieces are inlaid, is a paſte compounded of calcined marble, fine ſand, gum tragacanth, whites of eggs and oil. It is at firſt ſo ſoft, that the pieces are eaſily inſerted, and upon an overſight, may be taken out again, and the paſte new moulded for the admiſſion of other pins or ſtuds; but by degrees it grows as hard as a ſtone, ſo that no impreſſion can be made on the work. This paſte is ſpread within a wooden frame, which, for the large pieces, muſt not be leſs than a foot in breadth and thickneſs. This frame is faſtened with braſs tacks to a plate of the ſame metal, or to a ſtone ſlab; and as in capital pieces, which are often twenty feet by fifteen, this paſte-ground muſt be above three quarters of a foot deep, and the pins or ſtuds as long, it may eaſily be conceived of what weight ſuch a piece muſt be. The pieces deſigned for roofs, or any diſtant place, are not poliſhed; but in the altar-pieces, &c. nothing is wanting to give them the moſt beautiful and ſplendid appearance. A piece of about eighty feet ſquare, if performed with tolerable care and delicacy, will employ eight artiſts for the ſpace of two years. The ſtuds of the ſeveral colours lie ready before the artiſt in caſes, as the letters are laid before the compoſitors in a printing-houſe; and ſuch is their accuracy in imitating the fineſt ſtrokes of the pencil, that the only apparent difference betwixt the original painting and ſuch a copy, is, that the latter has a much finer luſtre, and the colours are more vivid.

Method of performing MOSAIC-WORK *of Marble and precious Stones.*—The ground of Moſaic-works, wholly marble, is uſually a maſſive marble, either white or black. On this ground the deſign is cut with a chiſſel, after it has been firſt calqued. After it has been cut of a conſiderable depth, i. e. an inch or more, the cavities are filled up with marble of a proper colour, firſt faſhioned according to the deſign, and reduced to the thickneſs of the indentures with various inſtruments. To make the pieces thus inſerted into the indentures cleave faſt, whoſe ſeveral colours are to imitate thoſe of the deſign, they uſe a ſtucco, compoſed of lime and marble-duſt; or a kind of maſtic, which is prepared by each workman, after a different manner peculiar to himſelf.

The figures being marked out, the painter or ſculptor himſelf draws with a pencil the colours of the figures, not determined by the ground, and in the ſame manner makes ſtrokes or hatchings in the place, where ſhadows are to be; and after he has engraven with the chiſſel all the ſtrokes thus drawn, he fills them up with a black maſtic, compoſed partly of burgundy-pitch poured on hot; taking off afterwards what is ſuperfluous, with a piece of ſoft ſtone or brick, which, together with water and beaten cement, takes away the maſtic, poliſhes the marble, and renders the whole ſo even, that one would imagine it only conſiſted of one piece.

This is the kind of Moſaic-work that is ſeen in the pompous church of the Invalids at Paris, and the fine chapel at Verſailles, with which ſome intire apartments of that palace are incruſtated.

As for Moſaic-work of precious ſtones, other and finer inſtruments are required than thoſe uſed in marble; as drills, wheels, &c. uſed by lapidaries and engravers on ſtone. As none but the richeſt marbles and ſtones enter this work, to make them go the further, they are ſawn into the thinneſt leaves imaginable, ſcarce exceeding half a line in thickneſs; the block to be ſawn is faſtened firmly with cords on the bench, and only raiſed a little on a piece of wood, one or two inches high. Two iron pins, which are on one ſide the block, and which ſerve to faſten it, are put into a vice contrived for the purpoſe, and with a kind of ſaw or bow, made of fine braſs wire, bent on a piece of ſpungy wood, together with emery ſteeped in water; the leaf is gradually faſhioned by following the ſtroke of the deſign, made on paper, and glued on the piece. When there are pieces enough faſtened to form an intire flower, or ſome other part of the deſign, they are applied to the ground.

The ground which ſupports this Moſaic-work is uſually of free-ſtone. The matter with which the ſtones are joined together, is a maſtic, or kind of ſtucco, laid very thin on the leaves as they are faſhioned; and this being done, the leaves are applied with plyers.

If any contour, or ſide of a leaf, be not either ſquared or rounded ſufficiently, ſo as to fit the place exactly, into which it is to be inſerted, when it is too large, it is to be brought down with a braſs file or raſp; and if it be too little, it is managed with a drill and other inſtruments uſed by lapidaries.

Moſaic-work of marble is uſed in large works, as in pavements of churches, baſilics, and palaces; and in the incruſtation and vaneering of the walls of the ſame edifices.

As for that of precious ſtones, it is only uſed in ſmall works, as ornaments for altar-pieces, tables for rich cabinets, precious ſtones being ſo very dear.

Moſaic-work of wood is more properly called marquetry. See MARQUETRY.

MOSQUE, a temple, or place of religious worſhip, among the Mahometans.

All moſques are ſquare buildings, generally built with ſtone; before the chief gate there is a ſquare court, paved with white marble, and low galleries round it, whoſe roof is ſupported by marble pillars. In theſe galleries the Turks waſh themſelves before they go into the moſque. In each moſque there is a great number of lamps; and between theſe, hang many cryſtal rings, oſtriches eggs, and other curioſities, which, when the lamps are lighted, make a fine ſhew. As it is not lawful to enter the moſques with ſhoes or ſtockings on, the pavements are covered with pieces of ſtuff ſewed together, each being wide enough to hold a row of men kneeling, ſitting, or proſtrate. The women are not allowed to enter the moſque, but ſtay in the porches without. About every moſque there are ſix high towers, called minarets, each of which has three little open galleries, one above another: theſe towers, as well as the moſques, are covered with lead, and adorned with gilding and other ornaments; and from thence, inſtead of a bell, the people are called to prayer by certain officers appointed for that purpoſe. Moſt of the moſques have a kind of hoſpital belonging to them, in which travellers, of what religion ſoever, are entertained during three days. Each moſque has alſo a place called Tarbé, which is the burying place of its founders; within which is a tomb ſix or ſeven feet long, covered with green velvet or ſattin, at the ends of which are two tapers, and round it ſeveral ſeats for thoſe who read the koran, and pray for the ſouls of the deceaſed.

MOSS, *Muſcus*, in botany, a very numerous order of plants, belonging to the cryptogamia claſs, the fructification of which is but little underſtood.

Moſſes are of conſiderable uſe in medicine; uſnea is eſteemed a good deſiccative and aſtringent; the cup-moſs is recommended in the chin-cough; the grey ground-lichen, or liverwort, againſt the bite of a mad dog; and other ſpecies, in other diſorders, as mentioned under their reſpective heads.

Moſs is frequently very injurious to fruit-trees, which grow upon cold barren ſoils, or where they are ſo cloſe planted as to exclude the free acceſs of the air; the only remedy, in ſuch caſes, is to cut down part of the trees, and to plough up the ground between thoſe left remaining; and in the ſpring-ſeaſon, in moiſt weather, you ſhould, with an iron inſtrument made a little hollow, the better to ſurround the branches of the trees, ſcrape off the moſs, carrying it off the place; and by two or three times thus cleanſing them, together with carefully ſtirring the ground, it may be entirely deſtroyed from the trees; but unleſs part of the trees are cut down, and the ground be well ſtirred, the rubbiſh of the moſs will ſignify little.

If the trees are covered with moſs, on account of the dryneſs of the ground, the proper remedy is to lay mud, from the bottom of a river or pond, pretty thick about their roots.

Moss is alſo a name given to boggy grounds in many parts of the kingdom. Theſe conſiſt of a turfy ſurface, below which is a black, moiſt, ſpongy earth, which being dug up with ſpades ſomewhat in the form of bricks, and dried, is what they call peats, uſed as fuel in ſeveral parts; and the upper ſcurf, being cut and dried, makes turfs, another coarſer ſort of fuel.

MOSTRA, in the Italian muſic, a mark at the end of a line or ſpace, to ſhew that if the firſt note be accompanied with a ſharp or flat, it is proper to place theſe characters along with the moſtra. Alſo if in a thorough-baſs this firſt note have any cyphers, theſe cyphers ſhould be put along with the moſtra, at the end of the preceding ſtaff. And, laſtly, if the part change its cleff with the firſt note, the cleff ought to be marked along with the moſtra, in the ſame manner.

MOTAZALITES, the name of a famous ſect among the Mahometans, properly ſignifying ſeparatiſts.

The Motazalites are not accounted orthodox muſſulmen, as they believe the alkoran to be created and not eternal; and beſides aſſert, that there are no attributes in God diſtinct from his eſſence.

MOTH, *Tinea*, or *Phalæna*, in zoology. See PHALÆNA.

MOTION is the continual and ſucceſſive change of place, and is either abſolute or relative.

Abſolute MOTION is the change of abſolute ſpace or place of bodies, as the flight of a bird, the motion of a projectile, &c.

Relative MOTION is the change of relative ſpace, or that which has reference to ſome other bodies; as of two ſhips under ſail, the difference of their velocities is the relative velocity or motion of the ſhip ſailing faſteſt; and is that alone which is diſcernible by us. The ſame is to be underſtood of abſolute and relative reſt.

To make this matter plainer, we are to conſider that ſpace is nothing elſe but an abſolute and infinite void, which it takes up or poſſeſſes; and that place may be conſidered either abſolutely or in itſelf alone; and then it is called the abſolute place of the body; or elſe with regard to the place of ſome other body, and then it is called the relative or apparent place of bodies. Now, as a motion is only the change of place in bodies, it is evident that it will come under the ſame diſtinction of abſolute and relative, or apparent. All motion is in itſelf abſolute, or the change of abſolute ſpace; but when the motions of bodies are conſidered and compared with each other, then are they relative and apparent only: they are relative, as they are compared to each other; and they are apparent only, inſomuch that not their true or abſolute motion, but the ſum or difference of the motions only is perceivable by us.

In comparing the motions of bodies we may conſider them as moving both the ſame way or towards contrary parts; in the firſt caſe the difference of motion is only perceived by us, in the latter the ſum of the motions. Thus for example; ſuppoſe two ſhips A and B ſet ſail from the ſame port upon the ſame rhumb, and that A ſails at the rate of five miles per hour, and B at the rate of three; here the difference of the velocity (viz. two miles per hour) is that by which the ſhip A will appear to go from the ſhip B forwards, or the ſhip B will appear at A to go with the ſame velocity backwards, to a ſpectator in either reſpectively.

If two ſhips A and B move with the ſame degree of velocity, then will the difference be nothing, and ſo neither ſhip will appear to the other to move at all. Hence it is that, though the earth is continually revolving about its axis, yet, as all objects on its ſurface partake of the ſame common motion, they appear not to move at all, but are relatively at reſt.

If two ſhips A and B, with the degrees of velocity as above, meet each other, the one will appear to the other to move with the ſum of both velocities, viz. at the rate of eight miles per hour; ſo that in this caſe the apparent motion exceeds the true, as in the other it fell ſhort of it. Hence the reaſon why a perſon, riding againſt the wind, finds the force of it much greater than it really is; whereas, if he rides with it, he finds it leſs.

The reaſon of all theſe phænomena of motion will be evident, if we conſider we muſt be abſolutely at reſt, if we would diſcern the true or real motion of bodies about us. Thus a perſon on the ſtrand will obſerve the ſhips ſailing with their real velocity. A perſon ſtanding ſtill will experience the true ſtrength and velocity of the wind; and a perſon placed in the regions between the planets, will view all their true motions, which he cannot otherwiſe do, becauſe in all other caſes the ſpectator's own motion muſt be added to, or ſubtracted from, that of the moving body, and the ſum, or difference, is therefore the apparent or relative motion, and not the true.

Motion is alſo either equable or accelerated.

Equable MOTION is that by which a body paſſes over equal ſpaces in equal times.

Accelerated MOTION is that which is continually augmented or increaſed, as retarded motion is that which continually decreaſes; and if the increaſe or decreaſe of motion be equal in equal times, the motion is then ſaid to be equally accelerated or retarded.

Equable MOTION is generated by a ſingle impetus or ſtroke; thus the motion of a ball from a cannon is produced by the ſingle action of the powder in the firſt moment, and therefore the velocity it firſt ſets out with would always continue the ſame, were it void of gravity, and to move in an unreſiſting medium, which therefore would be always equable, or ſuch as would carry it through the ſame length of ſpace in every equal part of time.

Hence we may determine the theorems for the expreſſions of the time, velocity, and the ſpace paſſed over in equable or uniform motion very eaſily thus:

Let T and t repreſent the times of a body moving with the velocities V and v, whereby the ſpaces S and s are reſpectively deſcribed; then as the ſpace deſcribed can only be influenced by the time and velocity, it follows, that $S=T\times V$, and $s=t\times v$; whence $S:s::T\times V:t\times v$; therefore $S\times t\times v=s\times T\times V$: from this general equation, we have $T:t::S\times v:s\times V$, and $V:v::S\times t:s\times T$; that is, the times are as the ſpaces directly, and the velocities inverſely; or in other words, they increaſe with the ſpaces, and decreaſe with the velocities, and the velocities are directly as the ſpaces, and inverſely as the times, and conſequently they increaſe with the ſpaces, and decreaſe with the times.

Accelerated motion is produced by a conſtant impulſe or power, which keeps continually acting upon the body, as that of gravity, which produces the motion of falling bodies; which motion is conſtantly accelerated, becauſe gravity every moment adds a new impulſe, which generates a new degree of velocity; and the velocity thus increaſing, the motion muſt be quickened each moment, or fall faſter and faſter the lower it falls.

In like manner a body thrown perpendicularly upward, and as a ball from a cannon, will have its motion continually retarded, becauſe gravity acts conſtantly upon it in a direction contrary to that given it by the powder, ſo that its velocity upwards be continually diminiſhed, and ſo its motion as continually retarded, till at laſt it be all deſtroyed. The body has then attained its utmoſt height, and is for a moment motionleſs, after which it begins to deſcend with a velocity in the ſame manner accelerated, till it comes to the earth's ſurface.

The motion generated by a uniformly accelerating force in any given time, is always proportional to that force, it being the genuine and natural effect thereof; and ſince in all the ſeveral parts of time, the force remains the ſame, and has the ſame efficacy; therefore the motion generated will alſo be as the time; whence univerſally the motion generated is in the compound ratio of both the force and the time of acting.

The quantity of motion is as the matter and velocity; therefore the velocity is as the motion directly and the matter reciprocally, and the velocity generated (or deſtroyed) in any time, is as the force and time directly, and the quantity of matter reciprocally.

The ſpace deſcribed from the beginning of the motion generated by an uniform accelerative force, is in the compound ratio of the laſt velocity, and the time wherein it

is generated. For imagine the time divided into an infinite number of equal parts, each of which call 1, and let the times from the beginning be 1, 2, 3, 4, &c. to t; and let c denote the velocity generated in the time 1; then the velocity generated in the ſame body, by the ſame force, in the times 1, 2, 3, 4, t, will be reſpectively c, $2c$, $3c$, $4c$, to tc; and it being well known that the ſpace deſcribed in each given part of time is as the time (1), and the velocity; it follows, that the ſpaces deſcribed in the ſeveral parts of time will be c, $2c$, $3c$, tc; and the ſum of theſe, or $\frac{tc}{2} \times t$, will repreſent the whole ſpace deſcribed by the moving body: but tc is the laſt velocity, and t the whole time; therefore the whole ſpace is as $tc \times t$, or the velocity and time conjunctly. It appears from hence, that if a body moves uniformly forward with the velocity acquired by an uniform accelerative force; it will deſcribe twice the ſpace in the ſame or an equal time that it deſcribed by the accelerative force.

But to illuſtrate this in a more general manner, let b repreſent any body or quantity of matter; F the accelerative force, acting uniformly on the body b; v the velocity generated in b by the force F; m, the motion generated in b; s, the ſpace deſcribed by the body b; and t, the time of deſcribing the ſpace s. Then $b = \frac{m}{v}$, $bv = \mathrm{F}t$, $v = \frac{s}{t}$, $\frac{\mathrm{F}t}{b} = \sqrt{\frac{\mathrm{F}s}{b}} = \frac{m}{b}$, $s = \frac{bvv}{\mathrm{F}} = \frac{\mathrm{F}tt}{b}$, $t = \frac{m}{\mathrm{F}}$, $\mathrm{F} = \frac{bv}{t} = \frac{bs}{tt} = \frac{bvv}{b} = \frac{m}{t}$.

If the accelerative force be ſuppoſed as the n power of the diſtance, then in order to inveſtigate the velocity acquired by a heavy body, falling from a ſtate of reſt, thro' a certain ſpace defined by x; let $\dot{x}$ repreſent the infinitely ſmall ſpace deſcribed by the falling body with the velocity acquired by the deſcent through x, which is here denoted by v, then will $\frac{\dot{x}}{v}$ repreſent the time of deſcribing $\dot{x}$. Now the force being as x^n, we ſhall have $x^n \times \frac{\dot{x}}{v} = \dot{v}$, it being well known that the velocity is always proportional to the time drawn into the given force; therefore $x^n \dot{x} = v\dot{v}$, and by taking the fluent of each ſide the equation, we have $\frac{x^{n+1}}{n+1} = \frac{vv}{2}$; conſequently $v = x^{\frac{n+1}{2}} \times \frac{2}{n+1}$; but as the factor $\frac{2}{n+1}$ is a conſtant quantity, it follows, that the velocity v is always as $x^{\frac{n+1}{2}}$, or as the ſquare-root of ſuch a power of the ſpace deſcribed, as is expounded by $n+1$.

MOTIONS, in war, the marches, counter-marches, &c. of an army in changing its poſt. See the article MARCH, &c.

MOTORY NERVES, in anatomy, the third pair, joining to the eyes.

MOTTO, in armoury, a ſhort ſentence or phraſe carried in a ſcroll, generally under, but ſometimes over the arms; ſometimes alluding to the bearing, ſometimes to the name of the bearer, and ſometimes containing whatever pleaſes the fancy of the deviſer.

MOVEABLE, in general, denotes any thing capable of being moved.

The moveable feaſts are ſuch as are not regularly held on the ſame day of the year or month, though they are always on the ſame day of the week. Thus Eaſter, which is that moveable feaſt on which all the reſt depend, is held on the Sunday which falls upon, or next after, the firſt full-moon following the twenty-firſt of March; and all the other feaſts keep a regular and certain diſtance from it; ſuch as Septuageſima, Sexageſima, Aſh-Wedneſday, Aſcenſion-day, &c. which ſee under their proper articles.

MOVEMENT, in mechanics, a machine that is moved by clock-work; for the theory of which, ſee the article CLOCK, WATCH, &c.

MOULD, or MOLD, in the mechanic arts, &c. a cavity cut with a deſign to give its form or impreſſion to ſome ſofter matter applied therein, of great uſe in ſculpture, foundery, &c.

MOULDS, in the manufacture of paper, are little frames compoſed of ſeveral braſs or iron-wires, faſtened together by another wire ſtill finer. Each mould is of the bigneſs of the ſheet of paper to be made, and has a rim or ledge of wood to which the wires are faſtened; theſe moulds are more uſually called frames, or forms.

Furnace and Crucible-makers MOULDS are made of wood, of the ſame form with the crucibles; that is, in form of a truncated cone: they have handles of wood to hold and turn them with, when, being covered with the earth, the workman has a mind to round or flatten his veſſel.

MOULDS *for Leaden Bullets* are little iron-pincers, each of whoſe branches terminates in an hemiſpherical concavity, which, when ſhut, form an entire ſphere: in the lips or ſides where the branches meet, is a little jet or hole through which the melted lead is conveyed.

Glaziers-MOULDS. The glaziers have two kinds of moulds, both ſerving to caſt their lead. In the one they caſt the lead into proper lengths fit to be drawn through the vice, and the grooves formed therein: this they ſometimes call ingot-mould. In the other they mould thoſe little pieces of lead a line thick, and two lines broad, faſtened to the iron-bars: theſe alſo go through the ſame apparatus as the former.

Goldſmith's-MOULDS. The goldſmiths uſe the bones of the cuttle-fiſh to make moulds for their ſmall works, which they do by preſſing the pattern between two bones, and leaving a jet or hole to convey the ſilver through, after the pattern has been taken out.

MOULD, among maſons, a piece of hard wood or iron hollowed withinſide, anſwerable to the contours of the mouldings or corniches, &c. to be framed: this is otherwiſe called caliber.

MOULDS, among plumbers, are the tables whereon they caſt the ſheets of lead. Theſe they ſometimes call ſimply tables; beſides which they have other real moulds wherewith they caſt pipes without ſoldering. See the article PLUMBERY.

MOULDS, among grinders of optic-glaſſes. See the article GRINDING.

MOULDS, among tallow-chandlers, are of two kinds: the firſt for the common dipped candles, being the veſſel wherein the melted tallow is diſpoſed, and the wick dipped: this is of wood, of a triangular form, and ſupported on one of its angles, ſo that it has an opening of near a foot at top: there is likewiſe one of lead ſubſtituted in the place of the former. The other, uſed in the fabric of mould candles, is of braſs, pewter, or tin; here each candle has its ſeveral mould. See the article CANDLE.

MOULD, among gold-beaters, a certain number of leaves of velom, or pieces of guts, cut ſquare, of a certain ſize, and laid over one another, between which they put the leaves of gold and ſilver, which they beat on the marble with the hammer. They have four kinds of moulds, two whereof are of velom, and two of gut; the ſmalleſt of thoſe of velom conſiſts of forty or fifty leaves, the largeſt contains an hundred: for the others, each contains five hundred leaves. The moulds have all their ſeveral caſes, conſiſting of two pieces of parchment, ſerving to keep the leaves of the mould in their place, and prevent their being diſordered in beating.

MOULD, in agriculture, a looſe kind of earth, every where obvious on the ſurface of the ground, called alſo natural or mother earth; by ſome alſo loam. See the article EARTH.

The goodneſs of a mould for the purpoſes of gardening, &c. may be known, according to Miller, by the ſight, ſmell, and touch. 1. Thoſe moulds that are of a bright cheſnut or hazelly colour, are counted the beſt: of this colour are the beſt loams, and alſo the beſt natural earth; and this will be the better yet, if it cut like butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall clods, is ſweet, will be tempered without cruſting or chopping in dry weather, or turning to mortar in wet. Next to that the dark grey and ruſſet moulds are accounted the beſt: but the light and dark aſh-coloured the worſt, ſuch as is uſually found on common heathy ground: the clear tawney is by no means to be approved; but that of a yellowiſh red colour is the worſt of all: this is commonly found in wild and waſte

parts

parts of the country, and for the moſt part produces nothing but goſs, furze, and fern, according as their bottoms are more or leſs of a light and ſandy, or of a ſpewey, gravel, or clayey nature. 2. All lands that are good and wholeſome, will, after rain, or breaking up by the ſpade, emit a good ſmell. 3. By the touch we may diſcover whether it conſiſts of ſubſtances entirely arenaceous, or clammy; or, as it is expreſſed by Mr. Evelyn, whether it be tender, fatty, deterſive, or ſlippery; or more harſh, gritty, porous, or friable.

MOULDINESS, a term applied to bodies which corrupt in the air, from ſome hidden principle of humidity therein; and whoſe corruption ſhews itſelf by a certain white down, or lanugo, on their ſurface, which, viewed through a microſcope, appears like a kind of meadow, out of which ariſe herbs and flowers, ſome only in the bud, others full blown, and others decayed, each having its root, ſtalk, and other parts. See CORRUPTION and VEGETATION.

MOULDING, any thing caſt in a mould, or that ſeems to have been ſo, though in reality it were cut with a chiſſel, or the ax.

Moulding of figures in paſte is done as follows: take the crumb of a new drawn white loaf, beat it, and roll it with a rolling-pin as fine and as far as it will go; then print it on the moulds; and when it has taken the ſuitable figure you deſire, dry it in a ſtove, and it will be very hard: and to preſerve it from vermin, you may mix a little powder of aloes with it.

To mould ſmall figures of jaſper-colour: oil your moulds with a fine pencil, and diverſify them with ſuch colours as you pleaſe, with gum-tragacanth; if they ſpread or run, put a little of the gall of an ox, for the thicker it is, the harder it will be; then mould your paſte of the colour of jaſper, or the like; put it in to fill the mould; tie it with a wire, and take it out; repair and varniſh it, and ſet it to harden.

MOULDINGS, in architecture, projectures beyond the naked wall, column, wainſcot, &c. the aſſemblage of which forms corniches, door-caſes, and other decorations of architecture. See plate XC. *fig.* 4.

Some mouldings are ſquare, others round, ſome are ſtraight, others curved, &c. and ſome are plain, others carved, or adorned with ſculpture, either hollowed or in relievo: ſome again are crowned with a fillet, others are without, as the doucine, talon, ovolo, torus, ſcotia, aſtragal, gula, corona, &c. See the articles DOUCINE, &c.

Mouldings are in architecture, what letters are in writing; by the various diſpoſitions and combinations of mouldings may be made an infinite number of different profiles, for all ſorts of orders and compoſitions, regular, or irregular; and yet all the kinds of mouldings may be reduced to three, viz. ſquare, round, and mixed, that is, compoſed of the other two: for this reaſon, thoſe who invented the Gothic architecture, reſolving to recede from thoſe perfect figures, and affecting to uſe others leſs perfect, to diſtinguiſh their architecture from the antique, introduced a new ſet of whimſical mouldings and ornaments. Regular mouldings are either large, as doucines, ovolos, gulas, talons, ſcotias, &c. or ſmall, as fillets, aſtragals, conges, &c.

MOULDING, in ſhip-building, the jettings or projectures beyond the level of the ſide. They are placed above one another, the intervals of which are generally ornamented with martial inſtruments, trophies of war, marine, and other emblematical figures, &c.

MOULINET is uſed, in mechanics, to ſignify a roller, which being croſſed with two levers, is uſually applied to cranes, capſtans, and other ſorts of engines of the like nature, to draw ropes, and heave up ſtones, &c.

MOULINET is alſo a kind of turnſtile, or wooden croſs, which turns horizontally upon a ſtake fixed in the ground, uſually placed in paſſages to keep out horſes, and to oblige paſſengers to go and come one by one. Theſe moulinets are often ſet near the outworks of forfeited places at the ſides of the barriers, through which people paſs on foot.

MOULTING, or MEWING. See the article MEWING.

MOUND, a term uſed for a bank or rampart, or other fence, particularly that of earth.

MOUND, in heraldry, a ball or globe with a croſs upon it, ſuch as our kings are uſually drawn with, holding it in their left hands, as they do the ſceptre in the right.

MOUNT-EGG. In the tin-works, after the tin from the burnt ore is melted down and remelted, there will ſometimes remain a different ſlag in the bottom of the float; this they call mount-egg; and though of a tin-colour, yet is of an iron-nature, as hath been found by applying a magnet to it.

MOUNT *of Piety*, certain funds or eſtabliſhments in Italy, where money is lent out, on ſmall ſecurity. We had alſo mounts of piety in England raiſed by contribution, for the benefit of people ruined by the extortions of the Jews.

MOUNTAIN, *Mons*, a part of the earth, riſing to a conſiderable height above the level of the ſurface thereof.

The origin of mountains is variouſly aſſigned by philoſophers: ſome will have them coeval with the world, and created along with it; others, among whom is Dr. Burnet, will have them to take their riſe from the deluge, urging that the extreme irregularity and diſorder viſible in them, plainly ſhews they do not come immediately out of the hand of God, but are the wrecks of the old world, broken into the abyſs. See DELUGE.

Others again allege, from hiſtory, that the roots of many hills being eaten away, the hills themſelves have ſubſided and ſunk into plains; whence they conclude, that where the corruption is natural, the generation is ſo too. It appears certain to many, that ſome mountains muſt have been generated gradually, and have thrown up in proceſs of time, from the ſea-ſhells, &c. found in them, which they ſuppoſe may be accounted for, from a violent wind blowing the ſand, &c. into huge heaps, which were made into a maſs by the rain, &c. The origin of mountains, in the opinion of Mr. Ray, ſeems to have been from exploſions, by means of ſubterraneous fires; and he thinks it very probable, that they all have vaſt hollows beneath them; and that this might have been the means uſed at the creation, to make the dry land appear, he thinks no way diſſonant to reaſon, ſince hiſtory proves that fires have raged in ſubterraneous caverns under the ſeas; and there is no natural impoſſibility in fire's ſubſiſting in ſuch caverns, even when the earth was all over covered with water, as at the firſt creation.

Mountains appear to many, defects and blemiſhes in the earth; but they are truly of the utmoſt uſe and neceſſity to the well-being both of man and other animals. They ſerve as ſcreens to keep off the cold and nipping blaſts of the northern and eaſtern winds; they ſerve for the production of a great number of vegetables and minerals, which are not found in any other ſoil; the long ridges and chains of lofty and topping mountains being generally found to run from eaſt to weſt, ſerve to ſtop the evagation of the vapours towards the poles, without which they would all run from the hot countries, and leave them deſtitute of rain. Mr. Ray adds, that they condenſe theſe vapours, like alembic heads, into clouds, and ſo, by a kind of external diſtillation, give origin to ſprings and rivers; and, by amaſſing, cooling, and conſtipating them, turn them into rain, and by that means render the fervid region of the torrid zone habitable.

MOUNTING, in the mechanic arts, ſomething that ſerves to raiſe or ſet off a work: thus, the frame and its dependences make the mounting of a looking-glaſs; the hilt, the mounting of a ſword; the fuſt, or but, the mounting of a carbine, muſquet, &c. and the mounting of a fan, is the ſticks which ſerve to open and ſhut it.

MOUNTING, in military affairs, ſignifies going upon duty: thus, mounting a breach, is running up to it; mounting the guard, is going upon guard; and mounting the trenches is going upon duty in the trenches: but mounting a cannon, mortar, &c. is the ſetting it on its carriage, or the raiſing its mouth.

MOURNERS, an order of penitents in the ancient Chriſtian church, who lay proſtrate in the porches of the churches, begging the prayers of the faithful, as they went in, and deſiring to do public penance in the church.

MOUSE,

MOUSE, in zoology, a ſpecies of mus, with a long and almoſt naked tail, and a white belly.

MOUSE, among ſailors, a ſort of riſing made on the ſtays and ſome other ropes in a ſhip, to prevent the eye, in one end of the rope, from ſlipping up above its proper place, or the body of it. The mouſe, which is a dump ſomething reſembling a pear, is raiſed by winding tarred canvas, called parſling, about the ſtay in one place, and afterwards a great many turns of ſpun-yarn: the whole is completed by weaving a coat or cover round the mouſe, very curiouſly, which laſt is called pointing. See the article POINTING.

MOUTH, in anatomy, a part of the face, conſiſting of the lips, the gums, the inſides of the cheeks, the palate, the ſalival glands, the os hyoides, the uvula, and the tonſils, which ſee under their proper articles.

MOXA, a ſort of cotton or downy ſubſtance, ſeparated from the leaves of a kind of Indian mugwort; uſed by the Eaſtern nations for cauterizing in certain parts of the body.

MUCILAGE, in pharmacy, is in general any viſcid and glutinous liquor.

MUCILAGE alſo denotes a thick pituitous matter, evacuated with the urine, in the gravel and dyſuria. See the articles STONE and DYSURIA.

MUCILAGE alſo imports the liquor which principally ſerves to moiſten the ligaments and cartilages of the articulations; and is ſupplied by the mucilaginous glands.

MUCILAGINOUS GLANDS, in anatomy, a very numerous ſet of glands, ſerving to ſecrete the mucilage of the joints. See GLAND.

MUCOUS GLANDS, in anatomy, three glands, which empty themſelves into the urethra; ſo called by their firſt diſcoverer, Mr. Cowper, from the tenacity of the liquor which they ſeparate.

MUCRO CORDIS, in anatomy, the lower or pointed end of the heart. See HEART.

MUCUS, a mucilaginous liquor ſeparated by the mucous glands, and the noſtrils.

MUFFLE, in metallurgy, an arched cover, reſiſting the ſtrongeſt fire, and made to be placed over coppels and teſts, in the operations of aſſaying, to preſerve them from the falling of coals and aſhes into them; though at the ſame time of ſuch a form as is no hindrance to the action of the air and fire on the metal, nor to the inſpection of the aſſayer. The muffles may be made of any form, providing they have theſe conditions; but thoſe uſed with coppels are commonly made ſemicylindrical; or when greater veſſels are employed, in form of a hollow hemiſphere. The muffle muſt have holes, that the aſſayer may look in; and the fore part of it muſt be always quite open, that the air may act better in conjunction with the fire, and be inceſſantly renewed: the apertures in the muffle ſerve alſo for the regimen of the fire, for the cold air ruſhing into the larger opening before, cools the bodies in the veſſel; but if ſome coals are put in it, and its aperture before be then ſhut, with a door fitted to it, the fire will be increaſed to the higheſt degree, much more quickly than it can be by the breathing holes of the furnace. Another uſe of theſe apertures is alſo, that the arſenical vapours of lead and antimony paſſing through the holes in the back part of the muffle, may not be offenſive to the aſſayer, who ſtands before it. As to the height, length, and depth of the muffles, theſe muſt be proportioned to the ſize and number of the veſſels they are intended to cover; and care muſt be taken in this, that all the parts of the inner ſurface of theſe veſſels be in the reach of the aſſayer's eye. The moſt frequent ſize of the muffle is, however, four inches high, ſix or eight long, and four or ſix inches broad. The ſegments cut off at the baſes, for the leſſer holes, muſt be of ſuch a proportioned height that the leaſt veſſels put under may not be in the way of coals or aſhes falling into them.

MUFTY, or MUPHTI, the chief of the eccleſiaſtical order, or primate, of the muſſulman religion. The authority of the mufti is very great in the Ottoman empire; for even the ſultan himſelf, if he would preſerve any appearance of religion, cannot, without hearing his opinion, put any perſon to death, or ſo much as inflict any corporal puniſhment.

The election of the mufti is ſolely in the grand ſignior, who preſents him with a veſt of rich ſables, &c. If he is convicted of treaſon, or any great crime, he is put into a mortar, kept for that purpoſe in the Seven Towers at Conſtantinople, and pounded to death.

MUGGLETONIANS, a religious ſect, which aroſe in England, about the year 1657; ſo denominated from their leader Lodowick Muggleton, a journeyman taylor, who, with his aſſociate Reeves, ſet up for great prophets, pretending, as it is ſaid, to have an abſolute power of ſaving and damning whom they pleaſed; and giving out, that they were the two laſt witneſſes of God that ſhould appear before the end of the world.

MUGWORT, in botany, the ſame with the artemiſia. See ARTEMISIA.

MUID, a large meaſure, in uſe among the French, for things dry. The muid is no real veſſel uſed as a meaſure, but an eſtimation of ſeveral other meaſures, as the ſeptier, mine, minot, buſhel, &c.

MUID is alſo one of the nine caſks, or regular veſſels uſed in France, to put wine and other liquors in. The muid of wine is divided into two demi-muids, four quarter-muids, and eight half-quarter-muids, containing thirty-ſix ſeptiers.

MULATTO, a name given in the Indies to thoſe who are begotten by a negro man on an Indian woman, or an Indian man on a negro woman.

MULBERRY, *Morus*, in botany, a genus of plants, having no corolla; the ſtamina are four ſubulated erect filaments, longer than the cup; there is no pericarpium; the cup is very large, carnoſe, ſucculent, and baccated, containing a ſingle ovato-acute ſeed.

There are ſeveral ſpecies of this tree; but two only are generally cultivated, called the black and white mulberry.

The black mulberry grows naturally in Perſia, from whence it was firſt brought to the ſouthern parts of Europe; but is now become common in every part of Europe, where the winters are not very ſevere: for in the northern parts of Sweden, theſe trees will not live in the open air; and in ſeveral parts of Germany they are planted againſt walls, and treated in the ſame way as peach and other tender fruits are here.

Theſe trees are generally of both ſexes, having male flowers or katkins, on the ſame tree with the fruit; but it often happens that ſome of the trees which are raiſed from ſeeds, have only male flowers, and produce no fruit; ſo that thoſe who plant theſe trees for their fruit, ſhould never make choice of ſuch as have been propagated by ſeeds, unleſs they have ſeen them produce fruit in the nurſery. It is alſo the ſureſt way to mark ſuch trees as are fruitful in the nurſery, at the time when their fruit is upon them, becauſe thoſe trees which are propagated by layers, are ſometimes of the male ſort.

The old mulberry trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; ſo that where there are any of theſe old trees, it is the beſt way to propagate from them, and to make choice of thoſe branches which are moſt fruitful. The uſual method of propagating theſe trees, is by laying down their branches, which will take root in one year, and are then ſeparated from the old trees; but as the moſt fruitful branches are often ſo far from the ground as not to be layed, unleſs by raiſing of boxes or baſkets of earth upon ſupports for this purpoſe, ſo the better way is to propagate them by cuttings, which, if rightly choſen and ſkilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a diſtance, and from the moſt fruitful branches. Theſe cuttings ſhould be the ſhoots of the former year, with one joint of two years wood to their bottom; the cuttings ſhould not be ſhortened, but planted their full length, leaving two or three buds above ground. The beſt ſeaſon for planting them is in March, after the danger of hard froſt is over; they ſhould be planted in light rich earth, preſſing the ground pretty cloſe about them; and if they are covered with glaſſes, it will forward their putting out roots; but where there is no ſuch conveniency, the ground about them ſhould be covered with moſs to prevent its drying; and where this is carefully done, the cuttings will require but little water, and will

ſucceed much better than with having much wet. If the cuttings ſucceed well and make good ſhoots, they may be tranſplanted the following ſpring into a nurſery, where they ſhould be regularly trained to ſtems, by fixing down ſtakes to each, to which the principal ſhoots ſhould be faſtened; and moſt of the lateral branches ſhould be cloſely pruned off, leaving only two or three of the weakeſt to detain the ſap, for the augmentation of the ſtem; for when they are quite diveſted of the ſide ſhoots, the ſap is mounted to the top, ſo that the heads of the trees grow too faſt for the ſtems, and become too weighty for their ſupport. In about four years growth in the nurſery, they will be fit to tranſplant where they are to remain; for theſe trees are tranſplanted with greater ſafety while young, than when they are of a large ſize.

The white mulberry is commonly cultivated for its leaves to feed ſilk-worms, in France, Italy, &c. though the Perſians always make uſe of the common black mulberry for that purpoſe; and it is ſaid that the worms fed with thoſe of the black produce much better ſilk than thoſe fed with the white; but it is to be obſerved, that the leaves of the black ſort ſhould never be given to the worms, after they have eaten for ſome time of the white, leſt the worms ſhould burſt, which is often the caſe when they are thus treated.

The trees which are deſigned to feed ſilk worms, ſhould never be ſuffered to grow tall, but rather kept in a ſort of hedge; and inſtead of pulling off the leaves ſingly, they ſhould be ſheared off, together with their young branches, which is much ſooner done, and not ſo injurious to the tree.

This white ſort may be propagated either from the ſeeds or layers, as the black mulberry, and is equally hardy; but the moſt expeditious method of raiſing theſe trees in quantity, is from the ſeeds, which may be procured in plenty from the ſouth of France and Italy. The beſt way to ſow theſe ſeeds in England, is to make a moderate hot bed, which ſhould be arched over with hoops, and covered with mats; upon this bed the ſeeds ſhould be ſown in the middle of March, and covered over with light earth about a quarter of an inch deep: in very dry weather the bed muſt be frequently watered, and in the heat of the day ſhaded with mats, and alſo covered in the nights when they are cold. With this management the plants will come up in five or ſix weeks, and as they are tender when they firſt appear, ſo they muſt be guarded againſt froſty mornings, which often happens in May. During the ſummer they muſt be kept clean from weeds, which is all the culture they require: but there muſt be care taken of them the firſt winter, eſpecially to cover them in autumn, when the firſt froſts come, which will kill the tender plants to the ground, if they are not protected; the following March theſe plants ſhould be tranſplanted into the nurſery, to get ſtrength, where they may remain two or three years, and then ſhould be removed where they are to continue.

This mild dulco-acid fruit is ſometimes uſed medicinally, as a refrigerant, antiſeptic, relaxant, attenuant, and aperient. Boerhaave looks upon the continued uſe of mulberries as one of the principal remedies in caſes of obſtruction and viſcidity, and in putrid diſorders; and Hoffmann gives inſtances of ſome obſtinate diſeaſes being cured by them: this fruit apparently promotes the alvine and urinary excretions; and in ſome fevers, where watery liquors run off almoſt unchanged, the urine is impregnated with the colour of the juice of the berries. To perſons of a bilious temperament and rigid fibres, and where the habit is diſpoſed, naturally or from extrinſic cauſes, to an inflammatory or putreſcent ſtate, their moderate, and even plentiful uſe, is ſalubrious: by thoſe of a cold inactive diſpoſition, where the veſſels are lax, the circulation languid, and the digeſtion weak, this fruit ſhould be taken very ſparingly.

MULCT, a fine of money laid upon a man, who has committed ſome fault or miſdemeanor.

MULE, in zoology, a mongrel kind of quadruped, uſually generated between an aſs and a mare, and ſometimes between a horſe and a ſhe-aſs. The mule is a ſort of a monſter, of a middle nature between its parents, and therefore incapable of propagating its ſpecies; ſo careful is nature to avoid filling the world with monſters. Mules are chiefly uſed in countries where there are rocky and ſtony roads, as about the Alps, Pyrenees, &c. Great numbers of them are kept in theſe places; they are uſually black, ſtrong, well-limbed, and large, being moſtly bred out of the fine Spaniſh mares: the mules are ſometimes fifteen or ſixteen hands high. No creatures are ſo proper for carrying large burdens, and none ſo ſure-footed. They are much ſtronger for draught than our horſes, and are often as thick-ſet as our dray-horſes; and they will travel ſeveral months together, with ſix or eight hundred weight upon their backs: they are much hardier and ſtronger than horſes, and will live and work twice the age of a horſe; and thoſe mules which are light are fitter for riding than horſes, as to the walk and trot; but they are apt to gallop rough.

MULIER, in law, ſignifies the lawful iſſue born in wedlock, though begotten before.

MULLER, or MULLAR, denotes a ſtone flat and even at the bottom, but round a-top, uſed for grinding of matters on a marble. The apothecaries uſe mullers to prepare ſome of their teſtaceous powders, and painters for their colours, either dry or in oil.

Muller is alſo an inſtrument uſed by the glaſs-grinders; being a piece of wood, to one end whereof is cemented the glaſs to be ground. It is ordinarily about ſix inches long, turned round.

MULLET, *Mugil*, in ichthyology, a genus of the acanthopterygious fiſhes, the head of which is of a depreſſed form in the anterior part, and the body oblong and compreſſed. On each ſide of the head, below the noſtrils, there ſtands a little bone, which is ſerrated on its lower part; the eyes are not covered with a ſkin; and there are teeth on the tongue and palate, but none in the jaws or fauces; the branchioſtege membrane on each ſide contains ſix oſſicles; theſe are of a crooked figure, and the upper one, which is the broadeſt, is covered by the coverings of the gills in ſuch a manner, that only five appear.

MULLET, or MOLLET, in heraldry, a bearing in form of a flat, or rather of the rowel of a ſpur, which it originally repreſented.

MULSUM, MULSE, a liquor made of wine and honey, or even of wine and water.

MULTANGULAR, a figure, or body, which has many angles.

MULTILATERAL, in geometry, is applied to thoſe figures which have more than four ſides or angles, more uſually called polygons. See POLYGON.

MULTINOMIAL, or MULTINOMIAL ROOTS, in mathematics, ſuch roots as are compoſed of many names, parts, or members; as $a+b+d+c$, &c. See the article ROOT.

MULTIPLE, *Multiplex*, in arithmetic, a number which comprehends ſome other ſeveral times; thus 6 is a multiple of 2, and 12 is a multiple of 6, 4, and 3, comprehending the firſt twice, the ſecond thrice, &c.

MULTIPLE RATIO, or PROPORTION, is that which is between multiples. If the leſſer term of the ratio be an aliquot part of the greater, the ratio of the greater to the leſs is called multiple; and that of the leſs to the greater ſubmultiple. A ſubmultiple number is that contained in the multiple; thus, the numbers 1, 2, and 3, are ſubmultiples of 9. Duple, triple, &c. ratios, as alſo ſubduples, ſubtriples, &c. are ſo many ſpecies of multiple and ſubmultiple ratios. See RATIO.

MULTIPLICAND, in arithmetic, one of the factors in the rule of multiplication; being that number which is given to be multiplied by another, which is called the multiplicator, or multiplier.

MULTIPLICATION, in arithmetic, the art of multiplying one number by another, to find the product, or it is a compendious method of performing the operation of addition.

Thus the multiplication of 4 by 5 makes 20, that is, four times five amount to 20.

In multiplication the firſt factor, i. e. the number to be multiplied, or the multiplicand, is placed over that whereby it is to be multiplied, and the product under both.

A

An example or two will make the proceſs of multiplication eaſy.—Suppoſe 269 were to be multiplied by 8.—

Multiplicand	— —	269
Multiplier	— —	8
Product	— —	2152

The factors being thus diſpoſed, and a line drawn underneath (as in the example), I begin with the multiplicator thus: 8 times 9 make 72, ſet down 2, and carry 7 tens, as in addition; then 8 times 6 make 48, and 7 I carried, 55; ſet down 5, and carry five: laſtly, 8 times 2 make 16, and with 5 I carried, 21; which I put down: ſo coming to number the ſeveral figures placed in order, 2, 1, 5, 2, I find the product to be 2152.

If the multiplicator conſiſts of more than one figure, the whole multiplicand is to be added to itſelf; firſt, as often as the right hand figure of the multiplicator ſhews, then as often as the next figure of the multiplicator ſhews, and ſo on.—Thus 421×23 is equal to 421×3, together with 421×20. The product ariſing from each figure of the multiplicator, multiplied into the whole multiplicand, is to be placed by itſelf in ſuch a manner, that the firſt or right hand figure thereof may ſtand under that figure of the multiplicator from which the ſaid product ariſes. For inſtance;

Multiplicand — —	421
Multiplicator — — —	23
Particular product of 421×3 —	1263
Particular product of 421×20	842
The total product — —	9683

This diſpoſition of the right-hand figure of each product follows from the firſt general rule; the right-hand figure of each product being always of the ſame denomination with that figure of the multiplicator from which it ariſes.

Thus, in the example, the figure 2 in the product 842 is of the denomination of tens, as well as the figure 2 in the multiplicator. For 1×20, (that is, the 2 of the 23) $= 20$, or 2 put in the place of tens, or ſecond place.

Hence, if either of the factors have one or more cyphers on the right-hand, the multiplication may be performed without regarding the cyphers, till the product of the other figures be found, to which they are to be then affixed on the right. And if the multiplicator have cyphers intermixed, they need not be regarded at all.—Inſtances of each follow:

12 | 0	358 | 6000	24 | 00 3 | 0	8013 5006
120	2148000	72000	48078
			4006500
			40113078

Thus much is ſufficient for an idea of multiplication, where the multiplicator conſiſts wholly of integers; in the praxis whereof, it is ſuppoſed the learner is appriſed of the product of any of the nine digits multiplied by one another, eaſily learned from the common table, or otherwiſe.

There are alſo ſome abbreviations of this art.—Thus to multiply a number by 5, you need only add a cypher to it, and then halve it.—To multiply by 9, add a cypher to the given multiplicand, and ſubtract the multiplicand therefrom, the remainder muſt certainly be nine times the number which was given to be multiplied.—To multiply by 15, firſt multiply it by 10, which is done by annexing a cypher to it, to which add the product by 5, the ſum will be the required product.

Expedients for the more eaſy and expeditious multiplying large ſums are ſliding rules, and Nepier's bones; the want of which may be ſupplied by tabulating the multiplicand.

Where the multiplicator is not compoſed wholly of integers, as it frequently happens in buſineſs, where pounds are accompanied with ſhillings and pence; yards with feet and inches; the method of procedure, if you multiply by a ſingle digit, is the ſame as in ſimple numbers, only carrying from one denomination to another, as the nature of each ſpecie requires. E. gr. to multiply 123 *l.* 14 *s.* 9 *d.* 3 *q.* by 5; ſay, $5 \times 3q = 15q$; that is, 3 *d.* 3 *q.* write down the 3 *q.* and proceed, ſaying, $5 \times 9 = 45 d.$ that is, 3 *s.* 9 *d.* ſet down the 9 *d.* and proceed in the ſame manner through the reſt.

If you multiply by two or more digits, the methods of procedure are as follow:—Suppoſe I have bought 37 ells of cloth at 13 *l.* 16 *s.* 6 *d.* per ell, and would know the amount of the whole. I firſt multiply 37 ells by the 13 *l.* in the common method of multiplication by integers, leaving the two products without adding them up; then multiply the ſame 37 ells by 16 *s.* leaving, in the like manner, the two products without adding them. Laſtly, I multiply the ſame 37 by the 6 *d.* the product whereof is 222 *d.* which, divided by 12, gives 18 *s.* 6 *d.* and this added to the products of the 16 *s.* the ſum will be 610 *s.* 6 *d.* the amount of 37 ells at 16 *s.* 6 *d.* the ell. Laſtly, the 610 *s.* 6 *d.* are reduced into pounds, by dividing them by 20: upon adding the whole, the amount of 37 ells at 13 *l.* 16 *s.* 6 *d.* per ell will be found as in the following:

37 ells.	37 ells.	37 ells
At 13 pounds.	At 16 ſhillings.	At 6 pence.
111	222	222
37	37	
30.10.6	18.6	
Product 511.10.6	610.6	

Or thus: ſuppoſe the ſame queſtion; reduce the 13 *l.* 16 *s.* into ſhillings, the amount will be 276 *s.* reduce 276 *s.* into pence, adding 6, the amount will be be 3318 *d.* Multiply the 37 ells by 3318, the amount will be 122766 *d.* which divided by 12, and the quotient 10230 *s.* 6 *d.* reduced into pounds by cutting off the laſt figure on the right hand, and taking half of thoſe on the left, yields 511 *l.* 10 *s.* 6 *d.* the price of the 37 ells, as before. Though by theſe two methods any multiplication of this kind may be effected, yet the operations being long, we ſhall add a third much ſhorter.—Suppoſe the ſame queſtion: Multiply the price by the factors of the multiplicator, if reſolvable into factors; if not, by thoſe that come neareſt it; adding the price for the odd one, of multiplying it by what the factors want of the multiplier. So the work will ſtand thus; 37 ells at 16 *s.* 6 *d.*: $6 \times 6 = 36 \times 1 = 37$.

Therefore	— —	6	
		82	19 0
		497	14 0
		13	16 6
		511	10 6

The price of the 37 ells.

But the moſt commodious is the fourth method, which is performed by aliquot and aliquant parts—where you are to obſerve by the way, that aliquot parts of any thing are thoſe contained ſeveral times therein, and which divide without any remainder; and that aliquant parts are other parts of the ſame thing compoſed of ſeveral aliquot parts.

To multiply by aliquot parts, is, in effect, only to divide a number by 3, 4, &c. which is done by taking a 3^d, 4^{th}, 5^{th}, &c. from the number to be multiplied. Example.—To multiply, v. g. by 6 *s.* 8 *d.* Suppoſe I have 347 ells of ribband at 6 *s.* 8 *d.* per ell.

Multiplicand — —	347 ells.	
Multiplicator — —	6 *s.* 8 *d.*	
Product — — —	115 *l.* 13 *s.* 4 *d.*	

The queſtion being ſtated, take the multiplicator, which according to the table of aliquot parts, is the third; and ſay, the third of three is 1, ſet down 1; the third of 4 is 1, ſet down 1, remains 1, that is 1 ten, which added to 7 makes 17; then the third of 17 is 5; remain 2 units, i. e. two thirds, or 13 *s.* 4 *d.* which place after the pounds. Upon numbering the figures, 1, 1, and 5, integers, and 13 *s.* 4 *d.* the aliquot part remaining, I find the ſum 115 *l.* 13 *s.* 4 *d.*

For multiplication by aliquant parts: ſuppoſe I would multiply by the aliquant part 19 *s.* I firſt take for 10 *s.* half the multiplicand; then for 5, which is the fourth, and laſtly, for 4, which is the fifth. The products of the three aliquot parts that compoſe the aliquant part being added together, the ſum will be the total product of the multiplication, as in the following example; which may

may ſerve as a model for multiplication by any aliquant part that may occur.

Multiplicand	—	356 ells.
Multiplier	—	19 *s.*
		178 *l.* for 10 *s.*
		89 *l.* for 5 *s.*
		71 *l.* 4 *s.* for 4 *s.*
Product	—	338 *l.* 4 *s.*

For the Proof of MULTIPLICATION.—The operation is right when the product, divided by the multiplier, quotes the multiplicand; or divided by the multiplicand, quotes the multiplier. A readier way, though not abſolutely to be depended on, is thus: Add up the figures of the factors, caſting out the nines; and ſetting down the remainders of each, theſe multiplied together, and out of their product caſt away the nines, and ſet down the remainder; if this remainder agree with the remainder of the product, after the nines are caſt out, the work is right. This method of proving multiplication by caſting out the nines, depends upon a peculiar property of the number 9, which no other digit has, viz. that the remainder will be exactly the ſame, whether we divide any number whatſoever by 9, or firſt add together the digits compoſing that number, and then divide the ſum by 9. This premiſed, let F and f repreſent any propoſed factors or numbers that are to be multiplied together; then will $F \times f$ be the product: let alſo m and n repreſent the reſpective remainders after having divided each of thoſe factors by 9, or, which is the ſame thing, after having caſt out the nines: then it is evident that $F-m$, $f-n$, and $\overline{F-m} \times \overline{f-n}$ being reſpectively divided by nine, will exactly terminate without any remainder; but $\overline{F-m} \times \overline{f-n}$ is equal to $F \times f - Fm - fn + mn$, therefore Ff being divided by 9, muſt leave the ſame remainder as mn divided by 9; or the ſum of the digits in the product mn muſt, when divided by 9, leave the ſame remainder as the ſum of the digits in the product Ff would when divided by 9.

Croſs MULTIPLICATION, otherwiſe called duodecimal arithmetic, is an expeditious method of multiplying feet and inches by feet and inches. This is much uſed in meaſuring, &c.—The method is thus:

Suppoſe 5 feet 3 inches to be multiplied by 2 feet 4 inches: ſay,

	F.	I.
2 times 5 feet is 10 feet, and 2 times 3 is 6 inches:	5	3
again, 4 times 5 is 20 inches, or 1 foot 8 inches;	2	4
and 4 times 3 is 12 parts, or 1 inch: the whole	10	6
ſum makes 12 feet 3 inches. In this manner	1	8
you may manage yards, feet, inches, and parts,		1
&c.	12	3

MULTIPLICATION *of Algebra.*—In multiplication the general rule for the ſigns is, that when the ſigns of the factors are alike (i. e both + or both —) the ſign of the product is +; but when the ſigns of the factors are unlike, the ſign of the product is —.

Caſe 1. When any poſitive quantity, $+a$, is multiplied by any poſitive number, $+n$, the meaning is, that $+a$ is to be taken as many times as there are units in n; and the product is evidently na.

Caſe 2. When $-a$ is multiplied by n, then $-a$ is to be taken as often as there are units in n; and the product muſt be $-na$.

Caſe 3. Multiplication by a poſitive number implies a repeated addition: but multiplication by a negative implies a repeated ſubtraction. And, when $+a$ is to be multiplied by $-n$, the meaning is that $+a$ is to be ſubtracted as often as there are units in n; therefore the product is negative, being $-na$.

Caſe 4. When $-a$ is to be multiplied by $-n$, then $-a$ is to be ſubtracted as often as there are units in n; but to ſubtract $-a$ is equivalent to adding $+a$, conſequently the product is $+na$. The ſecond and fourth caſes may be illuſtrated in the following manner:

It is evident that $+a-a=0$; therefore if we multiply $+a-a$ by n, the product muſt vaniſh or be 0, becauſe the factor $a-a$ is 0. The firſt term of the product is $+na$ (by caſe 1.) Therefore, the ſecond term of the product muſt be $-na$, which deſtroys $+na$; ſo that the whole product muſt be $+na-na=0$. Therefore, $-a$ multiplied by $+n$ gives $-na$.

In the like manner, if we multiply $+a-a$ by $-n$, the firſt term of the product being $-na$, the latter term of the product muſt be $+na$, becauſe the two together muſt deſtroy each other, or their amount be 0, ſince one of the factors (viz. $a-a$) is 0. Therefore, $-a$ multiplied by $-n$ muſt give $+na$.

If the quantities to be multiplied are ſimple, find the ſign of the product by the laſt rule; after it place the product of the co-efficients, and ſet down all the letters after one another as before.

EXAMPLES.

Mult.	$+a$	$-2a$	$+6x$
By	$+a$	$+4b$	$-5a$
Product	$+ab$	$-8ab$	$-30ax$
Mult.	$-8x$	$+3ab$	
By	$-4a$	$-5ac$	
Product	$+32ax$	$-15aabc$.	

To multiply compound quantities, you muſt multiply every part of the multiplicand by all the parts of the multiplier taken one after another, and then collect all the products into one ſum: the ſum ſhall be the product required.

Mult.	$a+b$	$2a-3b$
By	$a+b$	$4a+5b$
Prod.	$aa+ab$	$8aa-12ab$
	$+ab+bb$	$+10ab-15bb$
Sum	$aa+2ab+bb$	$8aa-2ab-15bb$

Mult.	$2a-4b$	$xx-ax$
By	$2a+4b$	$x+a$
Prod.	$4aa-8ab$	$xxx-axx$
	$+8ab-16bb$	$+axx-aax$
Sum	$4aa..0.-16bb$	$xxx..0..-aax$

Mult. $aa+ab+bb$
By $a-b$
Prod. $aaa+aab+abb$
$-aab-abb-bbb$
Sum $aaa..0...0.....-bbb$

Products that ariſe from the multiplication of 2, 3, or more quantities, as abc, are ſaid to be of 2, 3, or more dimenſions; and thoſe quantities are called factors or roots.

If all the factors are equal, then theſe products are called powers; as aa or aaa are powers of a. Powers are expreſſed ſometimes by placing, above the root to the right hand, a figure expreſſing the number of factors that produce them, thus:

a	1ſt		a
aa	2d		a^2
aaa	3d	power of the root a,	a^3
$aaaa$	4th	and is generally expreſſed thus:	a^4
$aaaaa$	5th		a^5

Theſe figures which expreſs the number of factors that produce powers are called their indices or exponents; thus 2 is the index of a^2. And powers of the ſame root are multiplied by adding their exponents thus: $a^2 \times a^3 = a^5$. $a^4 \times a^3 = a^7$. $a^3 \times a = a^4$.

Sometimes it is uſeful not actually to multiply compound quantities, but to ſet them down upon the ſign of multiplication ($\times$) between them, drawing a line over each of the compound factors. Thus $\overline{a+b} \times \overline{a-b}$ expreſſes the product of $a+b$ multiplied by $a-b$.

MULTIPLICATION *of Surds.* When the quantities are pure ſurds of the ſame kind, multiply them together, and to their product prefix their radical ſign. Thus $\sqrt{b} \times \sqrt{a} = \sqrt{ba}$, and $\sqrt{\overline{ba+da}} \times \sqrt{ca} = \sqrt{\overline{bcaa+dcaa}}$.

If the ſurd quantities of the ſame kind are joined to rational quantities, then multiply the rational into the rational, and the ſurd into the ſurd, and join their products together. Thus $d\sqrt{bc} \times 3b\sqrt{a} = 3db\sqrt{bca}$, and $5cd\sqrt{\overline{ba+da}} \times 3a\sqrt{ca} = 15cda\sqrt{\overline{bcaa+dcaa}}$.

MUL-

MULTIPLICATOR, or MULTIPLIER, in arithmetic, a number multiplying another called the multiplicand.

MULTIPLYING GLASS, in optics, one wherein objects appear increased in number.

It is otherwise called a polyhedron, being ground into several planes, that make angles with each other; thro' which the rays of light, iſſuing from the ſame point, undergo different refractions, ſo as to enter the eye from every ſurface in a different direction.

MULTISIQUOUS PLANTS, thoſe which have after each flower many diſtinct, long, ſlender, ſiliquæ, or pods, in which their ſeed is contained: ſuch are bear's foot, columbine, houſe-leek, navel-wort, orpine, &c.

MULTITUDE, an aſſemblage or collection of a great number of diſtinct perſons or things: thus we ſay, a multitude of men, of horſes, of trees, &c.

MUM, a kind of malt-liquor, much drank in Germany; and chiefly brought from Brunſwic, which is the place of moſt note for making it. The proceſs of brewing mum, as recorded in the town-houſe of that city, is as follows: Take ſixty-three gallons of water that has been boiled till one-third part is conſumed, and brew it with ſeven buſhels of wheaten-malt, one buſhel of oat-malt, and one buſhel of ground beans; when it is tunned, the hogſhead muſt not be filled too full at firſt; as ſoon as it begins to work, put into it three pounds of the inner rind of fir; one pound of the tops of fir and beech; three handfuls of carduus benedictus; a handful or two of the flowers of roſa ſolis; add burnet, betony, marjoram, avens, penny-royal, and wild thyme, of each a handful and a half; of elder-flowers, two handfuls or more; ſeeds of cardamum bruiſed, thirty-ounces; barberries bruiſed, one ounce; when the liquor has worked a while, put the herbs and ſeeds into the veſſel; and, after they are added, let it work over as little as poſſible; then fill it up: laſtly, when it is ſtopped, put into the hogſhead ten new-laid eggs unbroken; ſtop it up cloſe, and drink it at two years end. Our Engliſh brewers, inſtead of the inner rind of fir, uſe cardamum, ginger, and ſaſſafras; and alſo add elecampane, madder, and red ſanders.

MUMMY, a body embalmed or dried, in the manner uſed by the ancient Egyptians: or the compoſition with which it is embalmed. There are two kinds of bodies denominated mummies: the firſt are only carcaſes dried by the heat of the ſun, and by that means kept from putreſaction: theſe are frequently found in the ſands of Lybia. Some imagine, that theſe are the bodies of deceaſed people buried there on purpoſe to keep them intire without embalming; others think they are the carcaſſes of travellers, who have been overwhelmed by the clouds of ſand raiſed by the hurricanes frequent in thoſe deſarts. The ſecond kind of mummies are bodies taken out of the catacombs, near Cairo, in which the Egyptians depoſited their dead, after embalming.

MUMMY, among gardeners, a kind of wax uſed in grafting and planting the roots of trees, made in the following manner; take one pound of black pitch, and a quarter of a pound of turpentine; put them together into an earthen pot, and ſet them on fire in the open air, holding ſomething in your hand to cover and quench the mixture in time, which is to be alternately lighted and quenched till all the nitrous and volatile parts be evaporated. To this a little common wax is to be added; and the compoſition is then to be ſet by for uſe.

Dr. Agricola directs its being uſed in planting pieces of the roots of trees, in the following manner: melt it, and having let it cool a little, dip in the two ends of the pieces of root, one after another; then put them in water, and plant them in the earth, the ſmall end downward, ſo that the larger may appear a little way out of the earth, in order to have the benefit of the air; then preſs the earth hard down about them that they may not receive too much wet. This work he recommends to be performed in the months of September, October, and November.

MUNDIC, in natural hiſtory, a metallic mineral more commonly called marcaſite.

MUNDIFICATIVES, *Mundifiers*, *Mundificativa*, in phyſic, cleanſing or deterging medicines.

The word is derived from the Latin *mundus*, clean.

MUNICIPAL, in the Roman civil law, an epithet which ſignifies, inveſted with the rights and privileges of Roman citizens. Thus the municipal cities were thoſe whoſe inhabitants were capable of enjoying civil offices in the city of Rome.

MUNIMENTS, or MINIMENTS, the writings relating to a perſon's inheritance, by which he is enabled to defend his title to his eſtate: or, in a more general ſenſe, all manner of evidences, ſuch as charters, feoffments, releaſes, &c.

MUNIMENT HOUSE, a little ſtrong room in a cathedral, college, or univerſity, deſtined for keeping the ſeal, charters, &c. of ſuch cathedral, college, &c.

MUNIONS, in architecture, are the ſhort upright poſts or bars which divide the ſeveral lights in a window frame.

MUNITION, the proviſions with which a place is furniſhed in order for defence; or that which follows a camp for its ſubſiſtence. See the article AMMUNITION.

MURAL, in general, any thing belonging to a wall, which the Latins call *murus*.

MURAL ARCH is a wall, or walled arch, placed exactly in the plane of the meridian, for fixing a large quadrant, ſextant, or other inſtrument, in order to obſerve the meridian altitudes of the heavenly bodies.

MURAL CROWN. See the article CROWN.

MURDER, or MURTHER, in law, is the wilful and felonious killing a perſon from premeditated malice; provided the party wounded, or otherwiſe hurt, die within a year and a day after the fact was committed.

MUREX, in natural hiſtory, a genus of univalve or ſimple ſhells, without any hinge, formed of a ſingle piece, and beſet with tubercles or ſpines; the mouth is large and oblong, and has an expanded lip, and the clavicle is rough.

MURRAIN, or GARGLE, a contagious diſeaſe among cattle.

The moſt remarkable murrain is that mentioned in the Philoſophical Tranſactions, which ſpread through Switzerland, Germany, into Poland, &c.

The contagion ſeemed to propagate itſelf in form of a blue miſt, which fell on the graſs where the cattle grazed, when whole herds, forbearing their food, almoſt died away in twenty-four hours. Upon diſſection were found large corrupted ſpleens, ſphacelous and corroded tongues, &c. And even the perſons who managed them were infected, and died like the beaſts.

Some imagined it had its riſe from noxious vapours thrown out of the earth, in three earthquakes perceived in the neighbourhood of the place where it began; though Dr. Slare thinks it rather owing to ſwarms of volatile inſects.

The antidote for the ſound, and medicine for the ſick, was equal parts of ſoot, gunpowder, brimſtone, and ſalt, with as much water as would waſh it down: a ſpoonful was the doſe.

MURREY, in heraldry, a kind of purple colour. See SANGUINE.

MUS, in zoology, a genus of quadrupeds, of the order of the agriæ, the characters of which are theſe: the fore-teeth are acute, and there are no canine teeth at all, the feet are divided, and the ears naked.

Of this genus there are a great many ſpecies, known by diſtinct Engliſh names; as the rat, mouſe, dor-mouſe, or ſorex, citille, agutis, guinea-pig, &c.

MUSA, the plantain tree, in botany, a genus of plants, the flower of which conſiſts of two petals; one of which is erect, and divided by five indentings at the edge; and the other is hollow, ſhorter, and nectariferous: the ſtamina are ſix, and the fruit is an oblong, triquetrous berry.

MUSCÆ VOLITANTES, certain dark ſpots, ſeen by many people on looking at the ſky, a candle, or other bright object; ſo called, from their reſembling flies.

MUSCADINE, a rich kind of wine, of the growth of Provence and Languedoc, in France.

MUSCLE, *Muſculus*, in anatomy, a part of the human body, deſtined to move ſome other part, and that in general by a voluntary motion, or ſuch as is dictated by the will; being compoſed principally of fleſh and tendinous fibres, which have alſo veſſels of all kinds, as arteries,

veins, nerves, and lymphatics; all which are ſurrounded by, or encloſed in, one common membrane.

The muſcular fibres are, according to the action they are intended for, of various directions; ſome ſtraight, others oblique, tranſverſe, annular, and ſpiral. Some conſiſt of one uniform ſeries of fibres, and on that account are called ſimple; others are compoſed of various, and often contrary courſes of fibres, and theſe being cloſely arranged together, the large one ſeems to be made up of a number of leſſer muſcles, and is therefore called compound; and the more of theſe cluſters of fibres, or ſmaller veſſels, enter into the compoſition of a larger one, the thicker and ſtronger it is.

A muſcle is divided, by anatomiſts, into the body, and the two extremities: the body *c* (plate XC. *fig.* 2.) is alſo called the venter or belly of the muſcle; and the two extremities, if white, are called tendons; whereof that marked *a* is the right, and *b* the left. Fig. 3. repreſents a ſimple muſcle opened, to ſhew the internal ſeries of fleſhy fibres; and *fig.* 5. exhibits a ſection of a regular compound muſcle, ſhewing the arrangement of fibres in each belly.

That extremity where the muſcle ariſes is called its head, caput; or its beginning, origin, or fixed point: and its other extremity, or end, is called its tail, moveable point, and often its tendon; and, finally, if this be broad and membranous, it is called an aponeuroſis.

In many of the muſcles, both the extremities are moveable: in theſe, that part which of the two is leaſt moveable, is always called the head, and the more moveable part the tail. This, however, cannot be done univerſally; ſince there are caſes in which that extremity of a muſcle, which was before the moveable point, becomes the fixed point; and *vice verſa*, as in the ſerrati antici, and ſome of the muſcles of the abdomen, not to mention any others.

Action of the MUSCLES. This conſiſts in the contraction of its belly, after whatever manner that is done: by this means its extremities approach toward each other; and by this means alſo the part in which the end of the muſcle is inſerted, moves as if it were drawn by a cord. Schelhammer is of opinion, that this contraction of the belly of the muſcle is effected by a corrugation of the fibres, in the ſame manner as we ſee an earthworm ſhorten and contract itſelf by corrugating its ſkin, &c. Morgagni, on the other hand, alledges, that, in order to underſtand the power of motion in a muſcle, we ought to attend to Wallis's experiment; by which it is evidently proved, that the ſmalleſt force imaginable of the air, driven thro' a cylindric tube into a bladder, will, by diſtending its width, and ſhortening its length, cauſe it to raiſe up, and ſuſtain a weight of ſixty or ſeventy pounds.

Others have demonſtrated, from hydroſtatical principles, that a very ſmall quantity of a fluid, directed thro' a ſmall cylindric tube, placed in a veſſel of a larger baſe, and already filled, will be able, in the ſame manner, to move and raiſe up a large weight; from whence they conclude, that the belly of a muſcle ſwells in the time of its contraction or action; and that this intumeſcence may, nay and muſt, have very great effects.

On the other hand, there are, among the lateſt and moſt celebrated writers, ſome who affirm that the belly of a muſcle does not ſwell or become diſtended at all in the time of its contraction. But it would be well, ſays Heiſter, if the aſſertors of this opinion would, while they forcibly draw up the under jaw to the upper, lay two or three of their fingers upon either the temporal or maſſeter muſcle; for in this caſe they would ſee the moſt evident of all conviction, that, while theſe muſcles act, their bellies are in reality diſtended, and rendered firmer. Or let them only, when the hand is placed in a proper ſituation, forcibly draw the thumb toward the firſt finger, and then they may both ſee and feel, that the muſcle between the thumb and the index ſwells, or is diſtended in its middle, as the action of drawing the thumb is performed. The reader who would enter more deeply into this diſquiſition, may conſult Borelli *de Motu Animalium*; Bernouilli *de Motu muſcul.* Berger's *Phyſiolog.* c. 22. Boerhaave's *Inſtitutes*, chap. of muſcular motion; and Mead's *Introduction to Cowper's Myographia*.

Among the muſcles, there are different ones that conſpire in the ſame action, and ſo perform the ſame motion as aſſociates: ſuch are the flexors or extenſors of the arm, and the like: hence theſe, and ſuch others as conſpire in the ſame manner to the ſame action, are called by authors focii and congeneres.

When, on the other hand, we regard the contrary actions of certain muſcles, as the extenſors of any part which act quite contrarily to the flexors, theſe are called antagoniſt muſcles; in this caſe both the kinds acting together, render the limbs rigid or immoveable: this action of the muſcles is called motus tonicus. It is alſo obſervable, that ſeveral of the muſcles, conſidered ſingly and ſeparately, perform other kinds of motions beſides thoſe aſcribed to them in regard to the whole part: thus the maſtoide muſcle, the rectus major capitis, &c. when they act on both ſides, bend the head forwards; but when only on one ſide, they draw the head obliquely downwards, and to one ſide. Hence, from the diverſity of the muſcles, which act either alone or conjunctly with their aſſociates, or with others, there ariſe ſeveral intermediate motions, quite different from the primary ones, and ſuch as have not hitherto been ſufficiently obſerved. This does not only happen in regard to the muſcles of the head, the flexors and extenſors, and the like, but to ſeveral others; and particularly to thoſe of the eyes, the lips, the jaws, the tongue, the neck, the abdomen, the arm, the carpus, &c. Theſe we are carefully to attend to, and explain to ourſelves, by what particular muſcles, acting diſtinctly, they are performed; otherwiſe we ſhall never be able to underſtand the various and wonderful motions of the parts. Winſlow, in his excellent obſervations on the actions of the muſcles, publiſhed in the Memoirs of the Paris-Academy, obſerves, among other curious things, that a great many of the motions of the muſcular parts are not owing to the ſuppoſed contraction, but to the relaxation of the muſcles on the oppoſite ſide.

MUSCLE, *Mytulus*, in natural hiſtory, a ſhell compoſed of two valves, of an oblong figure, and ſhutting cloſe all the way; the valves are both convex, and of a ſimilar ſhape: and the animal inhabiting it is called a tethys.

MUSCULAR, or MUSCULOUS, in anatomy, ſomething relating to, or partaking of the nature of a muſcle. See the article MUSCLE.

MUSEUM, a name which originally ſignified a part of the palace of Alexandria, which took up at leaſt one fourth of that city. This quarter was called the Muſeum, from its being ſet apart for the muſes and the ſtudy of the ſciences. Here were lodged and entertained the men of learning, who were divided into many companies or colleges, according to the ſciences of which they were the profeſſors; and to each of theſe houſes or colleges was allotted a handſome revenue. The foundation of this eſtabliſhment is attributed to Ptolemy Philadelphus, who here placed his library. Hence the word muſeum is now applied to any place ſet apart as a repoſitory for things that have an immediate relation to the arts.

MUSES, certain fabulous divinities amongſt the Pagans, ſuppoſed to preſide over the arts and ſciences: for this reaſon it is uſual for the poets, at the beginning of a poem, to invoke theſe goddeſſes to their aid. Some reckon the muſes to be no more than three, viz. Mneme, Aœde, and Melete; that is, memory, ſinging, and meditation: but the moſt antient authors, and particularly Homer and Heſiod, reckon nine; Clio, which means glory; Euterpe, pleaſing; Thalia, flouriſhing; Melpomene, attracting; Terpſichore, rejoicing the heart; Erato, the amiable; Polyhymnia, a multitude of ſongs; Urania, the heavenly; and Calliope, ſweetneſs of voice. To Clio, they attributed the invention of hiſtory; to Melpomene, tragedy; to Thalia, comedy; to Euterpe, the uſe of the flute; to Terpſichore, the harp; and to Erato, the lyre and lute; to Calliope, heroic verſe; to Urania, aſtrology; and to Polyhymnia, rhetoric.

The muſes are painted young, handſome, and modeſt; agreeably dreſſed, and crowned with flowers. Their buſineſs was to celebrate the victories of the gods, and to inſpire and aſſiſt the poets: hence the cuſtom of invoking their aid at the beginning of a poem. It muſt not, however, be imagined, that the antient poets themſelves

ſelves ever conſidered the deities thus invoked, as divine perſons from whom they expected any real help. Their addreſſes to the muſes are mere allegories, and manners of expreſſing themſelves poetically, as when they make gods of ſleep, of fame, of virtue; and other natural and moral things; under the name of muſe they prayed for the genius of poetry, and all the talents neceſſary for a happy execution of what they had undertaken.

MUSHROOM, *fungus*, in botany, a genus of imperfect plants, compoſed of a pedicle, crowned with a broad head, convex and ſmooth at the top; and hollow, foliated, lamellated, or fiſtulous on the under ſide.

Mr. Miller directs the following method of cultivating them. If you have no beds of your own that produce them, you ſhould look abroad in rich paſtures, during the months of Auguſt and September, till you find them; and then opening the ground about their roots, you will often find the earth full of ſmall white knobs, which are the off-ſets from the muſhrooms: theſe ſhould be carefully gathered, and preſerved dry with the earth about them. The muſhroom-beds ſhould be made of dung in which there is good ſtore of litter. Theſe beds ſhould be made on dry ground, and the dung be laid upon the ſurface about a foot thick, two feet and a half broad, and of a length in proportion to the quantity of muſhrooms deſired: it ſhould be covered about four inches deep with ſtrong earth; upon this lay more dung, about ten inches thick; then another layer of earth; ſtill drawing in the ſides of the bed, ſo as to form it like the ridge of an houſe, which may be done by three layers of dung and as many of earth. When the bed is finiſhed it ſhould be covered with litter, to keep out the wet and prevent its drying; in this ſituation it may remain eight or ten days, by which time it will be of a proper degree of warmth; the litter ſhould then be taken off, the ſides of the bed ſmoothed, and a covering of light rich earth ſhould be laid over the bed; upon this the ſmall roots or off-ſets of the muſhrooms ſhould be put, placing them two or three inches aſunder; then gently cover them about half an inch thick with the ſame light earth; and again put on the covering of litter. The great ſkill in managing theſe beds, is that of keeping them in a proper temperature of moiſture. By this means muſhrooms may be produced all the year; and when the beds are deſtroyed, the ſurface which contains the duſt and roots of the muſhrooms, ſhould be laid by in a dry place for a freſh ſupply, till the proper time of uſing it.

MUSIC is one of the ſeven ſciences, commonly called liberal, and comprehended alſo among the mathematical, as having for its object diſcrete quantity or number, but not conſidering it in the abſtract like arithmetic, but in relation to time and ſound, in order to make a delightful harmony: or, it is the art of diſpoſing and conducting ſounds conſidered as acute and grave; and proportioning them among themſelves, and ſeparating them by juſt intervals pleaſing to the ſenſe.

Mr. Malcolm defines it a ſcience that teaches how ſound, under certain meaſures of time and tune, may be produced; and ſo ordered and diſpoſed, as either in conſonance or ſucceſſion, or both, they may raiſe agreeable ſenſations.

MUSK, *Moſchus*, in the materia medica, an odoriferous, grumous ſubſtance, found in a little bag, ſituated near the umbilical region of an oriental quadruped, which is ſaid by ſome to bear the greateſt reſemblance to the goat, by others to the ſtag-kind. The beſt muſk is brought from Tonquin in China, an inferior ſort from Agria and Bengal, and a ſtill worſe ſort from Ruſſia.

Fine muſk comes over in round thin bladders, generally about the ſize of pigeon's eggs, covered with ſhort brown hairs well filled, and without any aperture, or any appearance of their having been opened. The muſk itſelf is dry, with a kind of unctuoſity; of a dark reddiſh brown, or ruſty blackiſh colour; in ſmall round grains, with very few hard black clots; perfectly free from any ſandy or other viſible foreign matter. Chewed, and rubbed with a knife on paper, it looks bright, yellowiſh, ſmooth, and free from grittineſs. Laid on a red-hot iron, it catches flame, and burns almoſt intirely away, leaving only an exceeding ſmall quantity of light greyiſh aſhes: if any earthy ſubſtances have mixed with the muſk, the quantity of the reſiduum will diſcover them.

This concrete has a bitteriſh ſubacrid taſte; and a fragrant ſmell, agreeable at a diſtance, but ſo ſtrong as to be diſagreeable when ſmelt too near, unleſs weakened by a large admixture of other ſubſtances. A ſmall quantity, macerated for a few days in rectified ſpirit of wine, imparts a deep colour, and a ſtrong impregnation to the ſpirit: this tincture of itſelf, diſcovers but little ſmell, the ſpirit covering or ſuppreſſing the ſmell; but on dilution it manifeſts the full fragrance of the muſk, a drop or two communicating to a quart of wine or watery liquors a rich muſky ſcent. The quantity of liquor which may thus be flavoured by a certain known proportion of muſk, appears to be the beſt criterion of the genuineneſs and goodneſs of this commodity; a commodity which is not only ſaid to vary in goodneſs according to the ſeaſon of its being taken from the animal, but which is oftentimes ſo artfully ſophiſticated, that the abuſes cannot be diſcovered by any external characters, or by any other known means than the degree of its ſpecific ſmell and taſte, which the above experiment affords the moſt commodious method of meaſuring. The rectified ſpirit takes up completely the active matter of the muſk; watery liquors extract it only in part. The ſhops endeavour to procure an union of its virtues with water by the intervention of ſugar: twelve grains of muſk and a dram of fine ſugar are thoroughly ground together, and ſix ounces by meaſure of damaſk roſe-water added by degrees: this intermedium, however, does not anſwer ſo effectually as could be wiſhed; the mixture, at firſt turbid, becoming clear on ſtanding for a little time, and depoſiting, along with the feculent matter, a great ſhare of the medicinal parts of the muſk: the moſt ſucceſsful medium for uniting muſk with water, appears to be mucilage of gum arabic. By diſtillation, water becomes ſtrongly impregnated with the ſcent of the muſk, and ſeems to elevate all its odoriferous matter; while rectified ſpirit, on the contrary, brings over little or nothing of it.

MUSK, a medicine of great eſteem in the Eaſtern countries, has lately come into uſe among us, alſo, in ſome nervous diſorders; though liable, by its ſtrong impreſſion on the organs of ſmell, to offend and diſorder hyſterical perſons and conſtitutions of great ſenſibility, yet, when taken internally, it is found to abate ſymptoms of that kind, which its ſmell produces, and to be one of the principal medicines of the antipaſmodic claſs. Dr. Wall informs us, that two perſons labouring under a ſubſultus tendinum, extreme anxiety, and want of ſleep, occaſioned by the bite of a mad dog, were perfectly relieved by two doſes of muſk of ſixteen grains each: that convulſive hiccoughs, attended with the worſt ſymptoms, were removed by a doſe or two of ten grains; that in ſome caſes, where this medicine could not, on account of ſtrong convulſions, be adminiſtered by the mouth, it proved of ſervice when injected as a clyſter: that he never met with any perſon, how averſe ſoever to perfumes, but could take it in the form of a bolus without inconvenience: that under the quantity of ſix grains, he never found much effect from it, but that when given to ten grains and upwards, it produces a mild diaphoreſis, without heating or giving any uneaſineſs, but on the contrary, abating pain and raiſing the ſpirits; and that after the ſweat has begun, a refreſhing ſleep generally ſucceeds. This medicine has been tried alſo in ſome maniacal caſes, in which it ſeemed to procure a temporary relief.

MUSKET, a fire arm borne on the ſhoulder, and uſed in war. The length of a muſket is fixed at three feet eight inches from the muzzle to the pan, and it carries a ball of ſixteen to the pound.

In fortification, the length of the line of defence is limited by the ordinary diſtance of a muſket-ſhot, which is about 120 fathoms; and the length of almoſt all military architecture is regulated by this rule.

MUSKET-BASKETS, in fortification. See the article BASKETS *of Earth*.

MUSKETOON, a kind of ſhort thick muſket, whoſe bore is the thirty-eighth part of its length: it carries five

ounces

ounces of iron, or ſeven and a half of lead, with an equal quantity of powder. This is the ſhorteſt ſort of blunderbuſſes. See BLUNDERBUSS.

MUSLIN, a fine thin ſort of cotton cloth, which bears a downy knap on its ſurface. There are ſeveral ſorts of muſlins brought from the Eaſt Indies, and more particularly from Bengal; ſuch as doreas, beteſſes, mulmuls, tanjeebs, &c.

MUSTER, in the marine, a ſummoning together the crew of any particular ſhip, and calling them ſeverally over by their names.

MUTE, *dumb*, in a general ſenſe, ſignifies a perſon that cannot ſpeak, or has not the uſe of ſpeech.

MUTE, in law, a perſon that ſtands dumb or ſpeechleſs, when he ought to anſwer, or to plead.

MUTE, in grammar, a letter which yields no ſound without the addition of a vowel. The ſimple conſonants are ordinarily diſtinguiſhed into mutes and liquids, or ſemivowels.

The mutes in the Greek alphabet are nine, three of which, viz. π, κ, τ, are termed tenues; three, β, γ, δ, termed mediæ; and three, φ, χ, θ, termed aſpirates.

The mutes of the Latin alphabet are alſo nine, viz. B, C, D, G, L, K, P, Q, T.

MUTILATION, the retrenching or cutting away any member of the body.

This word is alſo extended to ſtatues and buildings, where any part is wanting, or the projecture of any member, as a corniche or an impoſt, is broken off.

MUTULE, in architecture, a kind of ſquare modillion ſet under the corniche of the Doric order.

The only difference between the mutule and modillion conſiſts in this, that the former is uſed in ſpeaking of the Doric order, and the latter in the Corinthian.

MUZZLE *of a Gun or Mortar*, the extremity at which the powder and ball is put in; and hence, the muzzle-ring is the metalline circle, or moulding, that ſurrounds the mouth of the piece. See GUN.

MYLOGLOSSI, in anatomy, two muſcles of the tongue. See TONGUE.

They are ſo called, as ariſing from the roots of the dentes molares.

The word is formed of the Greek $\mu\upsilon\lambda\alpha\iota$, the grinders, and $\gamma\lambda\omega\sigma\sigma\alpha$, the tongue.

MYLOHYOIDÆI, in anatomy, are two muſcles of the os hyoides. See TONGUE.

MYOLOGY, *Myologia*, a treatiſe or deſcription of the muſcles. See MUSCLE.

The word is Greek, and formed of $\mu\upsilon\varsigma$, or $\mu\upsilon\omega$, a muſcle, and $\lambda o\gamma o\varsigma$, diſcourſe.

MYOPIA, or MYOPIAS, implies a ſhort-ſighted, or purblind perſon, who cannot ſee objects at a diſtance but confuſedly, and near ones diſtinctly, which is contradiſtinguiſhed from preſbyta. See the article PRESBYTA.

The word is Greek, and formed of $\mu\upsilon\omega$, to ſhut, and $\omega\psi$, the eye; becauſe people ſo affected generally half ſhut the eyes, when they look intenſely at an object.

This diſorder is owing to the too great convexity of the ball of the eye, and particularly of the cryſtaline humour; whereby the viſual rays concur before they reach the retina. For this reaſon, to ſee an object diſtinctly, they muſt either apply it cloſe to the eye, or uſe a concave glaſs.

MYOSOTIS, mouſe-ear, in botany, a genus of plants, with a monopetalous flower, ſemiquinquifid at the limb: the ſeeds are four, which are contained in the bottom of the cup.

MYOSURUS, mouſe-tail, in botany, a genus of plants, the flower of which conſiſts of five very ſmall petals; and its numerous ſeeds are diſpoſed in an imbricated order upon a receptacle.

MYRIAD, a term ſometimes uſed to denote ten thouſand.

MYRIOPHYLLUM, ſmall water milfoil, in botany, a genus of plants, without any flower petals; and the fruit is compoſed of four naked ſeeds.

MYRISTICA, the nutmeg-tree, a genus of trees, the characters of which are not fully aſcertained: it is ſaid to have no flower petals; and its fruit is a drupe, of a roundiſh figure, containing a ſingle ſeed, lightly ſulcated. See NUTMEG.

MYROBALANS, dried medicinal fruits, of the plum kind, brought from the Eaſt Indies.

Five ſorts have been diſtinguiſhed in the ſhops; but all of them have an unpleaſant, bitteriſh, very auſtere taſte; and ſtrike an inky blackneſs with ſolution of chalybeate vitriol. They are ſaid to have a gently purgative, as well as aſtringent and corroborating virtue; but in this country, they have long been entire ſtrangers to practice, and are now diſcarded by the colleges both of London and of Edinburgh, from their catalogue of officinals.

MYRRH, in the materia medica, a gummy reſinous concrete juice, of an oriental tree, of which we have no certain account. It comes over in glebes or drops, of various colours and magnitudes; the beſt ſort is ſomewhat tranſparent, friable, in ſome degree unctuous to the touch, of an uniform browniſh or reddiſh yellow colour, often ſtreaked internally with whitiſh ſemi-circular veins; of a moderately ſtrong, not diſagreeable, ſmell; and a lightly pungent, very bitter taſte, accompanied with an aromatic flavour, but not ſufficient to prevent its being nauſeous to the palate. There are ſometimes found among it hard ſhining pieces, of a pale yellowiſh colour, reſembling gum arabic, of no taſte or ſmell: ſometimes maſſes of bdellium, darker-coloured, more opake, internally ſofter than the myrrh, and differing from it both in ſmell and taſte: ſometimes an unctuous gummy reſin of a moderately ſtrong ſomewhat ungrateful ſmell, and a bitteriſh very durable taſte, obviouſly different both from thoſe of bdellium and myrrh: ſometimes likewiſe, as Cartheuſer obſerves, hard compact dark-coloured tears, of an offenſive ſmell, and a moſt ungrateful bitterneſs, ſo as, when kept for ſome time in the mouth, to provoke reaching. Great care is therefore requiſite in the choice of this drug.

This bitter aromatic gummy-reſin is a warm corroborant, deobſtruent, and antiſeptic. It is given from a few grains to a ſcruple and upwards, in uterine obſtructions, cachexies, putrid fevers, &c. and often employed alſo as an external antiſeptic and traumatic.

Myrrh diſſolves almoſt totally in boiling water, but as the liquor cools, a proportion of reſinous matter ſubſides. The ſtrained ſolution is of a dark yellowiſh colour, ſomewhat turbid, ſmells and taſtes ſtrongly of the myrrh, and retains both its taſte and a conſiderable ſhare of its ſcent, on being inſpiſſated with a gentle heat to the conſiſtence of an extract. By diſtillation with a boiling heat, the whole of its flavour ariſes, partly impregnating the diſtilled water, partly collected and concentrated in the form of an eſſential oil; which is in ſmell extremely fragrant, and rather more agreeable than the myrrh in ſubſtance, in taſte remarkably mild, ſo ponderous as to ſink in the aqueous fluid, whereas the oils of moſt, perhaps of all the other gummy-reſins ſwim: the quantity of oil, according to Hoffman's experiments, is about two drams from ſixteen ounces, and when the myrrh is of a very good kind, near three drams.

Rectified ſpirit diſſolves leſs of this concrete than water, but extracts more perfectly that part in which its bitterneſs, flavour, and virtues reſide: the reſinous matter, which water leaves undiſſolved, is very bitter; but the gummy matter, which ſpirit leaves undiſſolved, is inſipid, the ſpirituous ſolution containing all the active parts of the myrrh. Tinctures of myrrh, made by digeſting three ounces of the concrete in a quart of rectified or proof ſpirit, are kept in the ſhops, and given ſometimes internally from fifteen drops to a tea-ſpoonful, but oftener uſed among us externally for cleanſing ulcers and promoting the exfoliation of carious bones; both tinctures are of a reddiſh yellow colour. In diſtillation, rectified ſpirit brings over little or nothing of the flavour of the myrrh; the extract, obtained by inſpiſſating the tincture, is a fragrant, bitter, very tenacious reſin, amounting to one third or more of the weight of the myrrh employed.

MYRTIFORM, in anatomy, an appellation given to ſeveral parts, from their reſembling myrtle-berries: thus we meet with the myrtiform caruncles, and the myrtiform muſcle

muſcle of the noſe, which ariſes near the inciſorius of the upper-lip, and is inſerted into the alæ of the noſe. See CARUNCLE.

MYRTLE, in botany, an ever-green ſhrub, with oblong leaves, pointed at both ends; in the bloſſoms of which ſpring ſolitary white pentapetalous flowers, followed by black oblong umbilicated berries, full of white crooked ſeeds. It is a native of the ſouthern parts of Europe, from whence the ſhops have been uſually ſupplied with the berries, called myrtilli, which rarely come to perfection in our climate; nor does the ſhrub bear our ſevere winters without ſhelter.

The berries of the myrtle, recommended in alvine and uterine fluxes and other diſorders from relaxation and debility, appear to be among the mild reſtringents or corroborants: they have a roughiſh not unpleaſant taſte, accompanied with a degree of ſweetiſhneſs and aromatic flavour. The leaves have likewiſe a manifeſt aſtringency, and yield, when rubbed, a pretty ſtrong aromatic ſmell agreeable to moſt people.

There are ſeveral ſpecies of this plant, however, preſerved in our gardens; they are all eaſily propagated from cuttings. The beſt ſeaſon for this is July, and the ſtraighteſt and youngeſt vigorous ſhoots are to be choſen. Theſe ſhould be cut off about eight inches long, and the leaves of the lower part ſtripped off to about two inches high, and that part of the ſtalk twiſted which is to be placed in the ground; they are to be planted in pots of light rich earth, at about two inches diſtance from each other, obſerving to cloſe the earth very well about them, and give them a gentle watering. They are then to be removed into a moderate hot-bed, and ſhaded and watered once in two or three days, till they have taken root. In about a month's time they will be rooted, and will begin to ſhoot, and muſt then be inured, by degrees, to the air; and in Auguſt they ſhould be removed into the open air, but placed in a warm ſituation, and ſheltered from the winds; they ſhould ſtand here till October, and then be removed into a green-houſe, where they ſhould be placed ſo as to have as much air as poſſible. In the March following they ſhould be removed into ſeparate pots of rich earth, and in May ſet out to the open air in a warm and well defended place. They will require in the ſummer frequent waterings, and the dead leaves ſhould be carefully picked off. As they advance in growth, they are to be ſhifted at times into pots of a larger ſize; and this ſhould be done either in April or in Auguſt; and towards the end of October, they ſhould always be removed into the green-houſe.

MYSTERY, ſomething ſecret or concealed, impoſſible or difficult to comprehend. All religions, true or falſe, have their myſteries. The pagan religion was remarkably full of them. Ovid reckons it a great crime to divulge the myſtic rites of Ceres and Juno. The eleuſinia, or ſacred rites of Ceres, ſolemnized at Eleuſis, were called, by way of eminence, the myſteries; and ſo ſuperſtitiouſly careful were they to conceal theſe ſacred rites, that if any perſon divulged any part of them, he was thought to have called down ſome divine judgment on his head, and it was accounted unſafe to abide under the ſame roof with him; and Horace declares, that he would not put to ſea in the ſame ſhip with one who revealed the myſteries of Ceres. The pagan myſteries, it is true, were generally myſteries of iniquity, and concealed only becauſe their being publiſhed would have rendered their religion ridiculous and odious. Thus the ſacred writings often ſpeak of the infamous myſteries of the pagan deities, in which the moſt ſhameful crimes were committed under the ſpecious veil of religion.

The whole religion of the Egyptians was myſterious from the beginning to the end, and both their doctrine and worſhip wrapped up in ſymbols and hieroglyphics.

The religion of the Jews is ſuppoſed to be full of myſteries. The whole nation, according to St. Auguſtin, was a myſtery, as it repreſented or was a type of the people of Chriſt, and the Chriſtian religion. Whatever was commanded or forbidden them was figurative, and their ſacrifices, prieſthood, &c. included myſteries. The prophecies concerning Jeſus Chriſt in the Jewiſh books, are likewiſe figurative and myſterious.

The Chriſtian religion has alſo its myſteries; but in the Scripture language the word myſtery is uſed with ſome latitude, and denotes whatever is not to be known without a divine revelation, and all the ſecret things which God has diſcovered by his miniſters the prophets, by Jeſus Chriſt and his apoſtles. The myſteries of the Chriſtian church are, the incarnation of the word, the hypoſtatical union of the divine and human nature, the miraculous birth, death, and reſurrection of the Son of God, the doctrine of the trinity, &c. See the article INCARNATION, &c.

St. Paul often ſpeaks of the myſteries of the Chriſtian religion; as the myſtery of the goſpel, the myſtery of the croſs of Chriſt, the myſtery which was kept ſecret ſince the world began; and he calls the preachers of the goſpel, the ſtewards of the myſteries of God.

MYSTICAL, ſomething myſterious or allegorical.

MYSTICS, a religious ſect, diſtinguiſhed by their profeſſing a pure, ſublime, and perfect devotion, with an entire diſintereſted love of God, free from all ſelfiſh conſiderations, and by their aſpiring to a ſtate of paſſive contemplation.

MYTHOLOGY, *μυθολογια*, the hiſtory of the fabulous gods and heroes of antiquity, with the explanations of the myſteries or allegories couched therein. Lord Bacon thinks that a great deal of concealed inſtruction and allegory was originally intended in moſt part of the ancient mythology: he obſerves, that ſome fables diſcover a great and evident ſimilitude, relation, and connection with the thing they ſignify, as well in the ſtructure of the fable, as in the meaning of the names, whereby the perſons or actors are characterized.

The ſame writer thinks it may paſs for a farther indication of a concealed and ſecret meaning, that ſome of theſe fables are ſo abſurd and idle in their narration, as to ſhew an allegory even afar off: but the argument of moſt weight upon this ſubject he takes to be this, that many of theſe fables appear by no means to have been invented by the perſons who relate them: he looks on them not as the product of the age, nor invention of the poets, but as ſacred relics, as he terms them, gentle whiſpers, and the breath of better times, that from the tradition of more ancient nations, came at length into the flutes and trumpets of the Greeks. He concludes, that the knowledge of the early ages was either great or happy; great if they by deſign made this uſe of trope and figure; or happy, if, whilſt they had other views, they afforded matter and occaſion to ſuch noble contemplations.

MYURUS, in medicine, an epithet for a ſort of ſinking pulſe, when the ſecond ſtroke is leſs than the firſt; the third than the ſecond, and ſo on. Of this, there are two kinds; the firſt, when the pulſe ſinks ſo as never to ariſe; the other, when it returns again, and riſes in ſome degree. Both are eſteemed a bad preſage.

N.

NAH

N, A liquid conſonant, and the thirteenth letter of the Greek, Latin, Engliſh, &c. alphabets. It is formed from the old Greek, and that from the old Hebrew nun. Its ſound is formed by a ſtrong expreſſion of the voice through the mouth and noſtrils, being at the ſame time intercepted by applying the tongue to the fore palate, and the lips or mouth open. It ſuffers no conſonant immediately after it in the beginning of words or ſyllables; nor any before it but *g*, *k*, and *ſ*, as *gnaw*, *knave*, *ſnow*, &c.

As a numeral, N ſtands for 900; and with a daſh over it, thus $\bar{N}$, for 9000.

N. L. in the ancient law, ſtood for *non liquet*, meaning that the cauſe was not clear enough for ſentence.

N. or N°. in commerce, medicine, &c. is an abbreviation of *numero*, or number.

NAAM, in law, the detaching or diſtraining a perſon's moveable goods: as where a man takes another man's beaſt for doing damage in his ground, or where it is done in conſequence of another man's act, as when it is agreed, that in default of payment of ſome contract, it ſhall be lawful to diſtrain on lands charged therewith.

NABOB, a viceroy, or governor of one of the provinces of the mogul's empire, in India. See the article INDIA.

NABONASSAR, or *Æra of* NABONASSAR, a method of computing time from the commencement of Nabonaſſar's reign. See EPOCHA.

The epocha of Nabonaſſar is of the greater importance, as Ptolemy and other aſtronomers account their years from it.

NADAB, the ſovereign pontiff, or high prieſt of the Perſians, whoſe dignity is the ſame as that of the muſti among the Turks; with this difference only, that the nadab may diveſt himſelf of his eccleſiaſtical office, and paſs to civil employments, which the mufti is not allowed to do.

NADIR, in aſtronomy, that point of the heavens which is diametrically oppoſite to the zenith, or point directly over our heads.

The zenith and nadir are the two poles of the horizon. See HORIZON and POLE.

Sun's NADIR, in aſtronomy, is the axis of the cone formed by the earth's ſhadow: it is thus called, becauſe being produced, it gives a point in the ecliptic diametrically oppoſite to the ſun.

NAHUM, or *the Prophecy of* NAHUM, a canonical book of the Old Teſtament.

Nahum, the ſeventh of the twelve leſſer prophets, was a native of Elkoſhai, a little village of Galilee. The ſubject of his prophecy is the deſtruction of Nineveh, which he deſcribes in the moſt lively and pathetic manner; his ſtyle is bold and figurative, and can hardly be exceeded by the moſt perfect maſters of oratory. This prophecy was verified at the ſiege of that city by Aſtyages, in the year of the world 3378, 622 years before Chriſt.

The time of Nahum's death is unknown; the Greek menologies, and the Latin martyrologies, place his feſtival on the firſt of December.

NAI

NAIADS, in mythology, the nymphs of the fountains. See NYMPH.

NAIANT, in heraldry, a term uſed in blazoning fiſhes, when borne in an horizontal poſture, as if ſwimming.

NAIL, *Unguis*, in the animal body, a kind of horny ſubſtance growing over the ends of the fingers and toes of men, &c. much of the ſame nature with horn or the hoofs of beaſts.

The nails are looked upon by ſome as productions of the cutaneous papillæ, and by others as a continuation of the epidermis.

By maceration the epidermis may be ſeparated entire from the hands and feet; and, in this experiment, the nails part from the papillæ, and go along with the epidermis; and yet their ſubſtance and ſtructure appear to be very different from that of the epidermis.

The ſubſtance of the nails conſiſts of ſeveral planes of longitudinal fibres, ending at the extremity of each finger, being nearly of an equal thickneſs, but different lengths.

The graduated roots of all the fibres of which theſe planes conſiſt, are hollowed for the reception of the ſame number of very ſmall oblique papillæ, which are continuations of the true ſkin.

There are three parts generally diſtinguiſhed in the nails, namely, the root, body, and extremity. The root is white, and like a creſcent, and the greateſt part of it hid under the ſemi-lunar fold. The body of the nail is naturally arched, tranſparent, and of the colour of the cutaneous papillæ that lie under it. The extremity of the nail does not adhere to any thing, and grows, as often as it is cut.

The principal uſe of the nails is to ſtrengthen the ends of the fingers and toes, and to hinder them from being inverted towards the convex ſide of the hand or foot, when we handle or preſs upon any thing hard; ſo that they ſerve rather for buttreſſes than ſhields. *Winſlow.*

The Romans had their nails cut by artiſts, who made an employment of it.

The Chineſe doctors pique themſelves on the exceſſive length of their nails; ſome of them, according to Le Compte, being near as long as their fingers.

NAIL is alſo a meaſure of length, containing the ſixteenth part of a yard.

NAILS, in building, &c. ſmall ſpikes of iron, braſs, &c. which being drove into wood, ſerve to bind ſeveral pieces together, or to faſten ſomething upon them. The ſeveral ſorts of nails are very numerous; as 1. Back and bottom nails; which are made with flat ſhanks to hold faſt, and not open the wood. 2. Clamp-nails for faſtening the clamps in building, &c. 3. Claſp-nails, whoſe heads claſping and ſticking into the wood, render the work ſmooth, ſo as to admit a plane over it. 4. Clench-nails, uſed by boat and barge builders, and proper for any boarded buildings that are to be taken down; becauſe they will drive without ſplitting the wood, and draw without breaking; of theſe there are many ſorts. 5. Clout-nails, uſed for nailing on clouts to axle trees. 6. Deck-

Deck-nails, for faſtening of decks in ſhips, doubling of ſhipping, and floors laid with planks. 7. Dog-nails, for faſtening of hinges on doors, &c. 8. Flat-points, much uſed in ſhipping, and are proper where there is occaſion to draw and hold faſt, and no conveniency of clenching. 9. Jobent nails, for nailing thin plates of iron to wood, as ſmall hinges on cup-board-doors, &c. 10. Lead-nails, for nailing lead, leather, and canvas to hard wood. 11. Port-nails, for nailing hinges to the ports of ſhips. 12. Pound-nails, which are four-ſquare, and are much uſed in Eſſex, Norfolk, and Suffolk, and ſcarce any where elſe, except for paleing. 13. Ribbing-nails, principally uſed in ſhip-building, for faſtening the ribs of ſhips in their places. 14. Roſe-nails, which are drawn four-ſquare in the ſhank, and commonly in a round tool, as all common two-penny nails are; in ſome countries all the larger ſort of nails are made of this ſhape. 15. Rother-nails, which have a full head, and are chiefly uſed in faſtening rother-irons to ſhips. 16. Round-head nails, for faſtening on hinges, or for any other uſe where a neat head is required; theſe are of ſeveral ſorts. 17. Scupper-nails, which have a broad head, and are uſed for faſtening leather and canvas to wood. 18. Sharp-nails; theſe have ſharp-points and flat ſhanks, and are much uſed, eſpecially in the Weſt-Indies, for nailing ſoft wood. 19. Sheathing-nails, for faſtening ſheathing-boards to ſhips. 20. Square-nails, which are uſed for hard wood, and nailing up wall-fruit. 21 Tacks, the ſmalleſt of which ſerve to faſten paper to wood; the middling for wool-cards, &c. and the larger for upholſterers and pumps.

Nails are ſaid to be toughened when too brittle, by heating them in a fire-ſhovel, and putting ſome tallow or greaſe among them.

Nails are ſold at ſix ſcore to the hundred: in lathing, 500 are uſually allowed to a bundle of five feet laths, and 600 to a bundle of four feet laths: in flooring, 200 are ſufficient for a ſquare of flooring.

NAISSANT, in heraldry, is applied to any animal iſſuing out of the midſt of ſome ordinary, and ſhewing only his head, ſhoulders, fore-feet and legs, with the tip of his tail; the reſt of his body being hid in the ſhield, or ſome charge upon it; in which it differs from iſſuant, which denotes a living creature ariſing out of the bottom of any ordinary or charge.

NAKED, in architecture, is the ſurface or plane from whence the projectures ariſe, or which ſerves as a ground to the projectures. Thus, we ſay the foliages of a capital ought to anſwer to the naked of a column, and that a pilaſter ought to exceed the naked of the wall by ſo many inches.

NAKED FIRE, in chemiſtry, is an open fire; or one where a veſſel is immediately expoſed to the fire.

NAKOUS, a muſical inſtrument, conſiſting of two braſs-plates, which are ſuſpended by ſtrings, and ſtruck together ſo as to beat time: they are uſed in the Coptic churches in Egypt, and in the Mahometan proceſſions.

NAME, *Nomen*, denotes a word whereby men have agreed to expreſs ſome idea; or which ſerves to ſignify a thing or ſubject ſpoken of. This the grammarians uſually call a noun, though their noun is not of quite ſo great an extent as our name. See the article NOUN.

Names are either proper or appellative. Proper names are thoſe which repreſent ſome individual thing or perſon, ſo as to diſtinguiſh it from all other things of the ſame ſpecies, as Ariſtotle, which repreſents a certain philoſopher. Proper names are either called Chriſtian, as that given us at baptiſm, or ſurnames; the firſt impoſed for the diſtinction of perſons, anſwering to the Roman prænomen; the ſecond for the diſtinction of families, anſwering to the nomen of the Romans, and the patronymicum of the Greeks. See PATRONYMIC, &c.

Appellative, or general names, are thoſe which ſignify common ideas, or which are common to ſeveral individuals of the ſame ſpecies, as a horſe, animal, &c.

NAPE, a name uſed for the hind part of the neck, ſuppoſed to be on account of the ſhort hair growing there, in reſemblance of the nap of a cloth.

NAPHTHA, in natural hiſtory, a fluid mineral body, of a thin conſiſtence, bright and pellucid, of a ſtrong ſmell, very readily inflammable, and when pure, burning away without leaving any reſiduum.

The naphtha is found in conſiderable quantities floating on the water of certain ſprings, principally breaking out at the ſides of hills in Perſia, Tartary, and ſome parts of the empire of China, where if a lighted candle be held near the ſurface, it takes fire and overſpreads the ſurface of the water for a great extent, with a ſtrong white flame, and emits a very diſagreeable ſmell. The genuine naphtha is very rare in Europe; it is not known to be any where naturally produced here, and what we ſee of it is generally ſophiſticated. Diſtilled by the retort, it yields an oil ſomewhat thinner than it was originally, and of a weaker ſmell. The ſubſtance remaining at the bottom of the retort, has much the reſemblance of amber; and Dr. Hill thinks it highly probable, that the origin of all the amber in the world is from the ſame ſort of principle; nay he tells us that he has ſucceeded ſo far in an attempt to make amber by this fluid and an acid drawn from the crude pyrites, that he has produced a friable ſomewhat pellucid matter, having all the properties of amber except its hardneſs and clearneſs, and yielding a true ſalt and oil of amber on diſtillation. See AMBER.

The medicinal virtues of the naphtha are the ſame with the common petroleum, but in a more remiſs degree. It is uſed externally on many occaſions in Perſia; and is taken inwardly, a few drops for a doſe, in colics. The principal uſe made of it, however, is burning in lamps; for which purpoſe it is very proper.

NAPLES, the capital of the kingdom of Naples: ſituated in eaſt long. 15°, north lat. 41°.

The kingdom of Naples is one of the Sicilies; it is the ſouth-eaſt part of Italy, and is ſituated between 14 and 19° eaſt long. and between 38 and 43° north lat. being bounded by the gulph of Venice on the north-eaſt, by the Mediterranean ſea on the ſouth-eaſt, by Sicily and the Tuſcan ſea on the ſouth-weſt, and by the pope's territories on the north-weſt; and divided from the iſlands of Sicily only by the narrow ſtreight or pharo of Meſſina.

NARCISSUS, the daffodil, in botany, a genus of plants, the corolla of which conſiſts of a nectarium formed of one leaf of a cylindric or funnel ſhape, coloured at the top and wide, curled and plicated at the mouth, and of ſix oval acuminated plane petals affixed externally to the tube of the nectarium above its baſe: the fruit is a roundiſh obtuſely trigonal capſule, formed of three valves, and containing three cells, in which are a number of round appendiculated ſeeds, with a columnar receptacle.

The root of this plant is emetic, vulnerary, and detergent.

NARCOTICS, in medicine, opiates, or medicines which excite ſleep.

The word is Greek, ναρκωτικὸς, and derived from ναρκόω, to ſtupify, or benumb.

Narcotics act on the nervous membranes of the ſtomach and inteſtines, principally by means of a vaporous and fetid ſulphur. For, as the ſtomach and inteſtines firſt and immediately feel the force and efficacy of remedies, they are ſo much the more liable to ſuffer from the influence of medicines, which are of a ſtronger and more penetrating nature than ordinary. Opium or any other narcotic, after it is taken, and begins to be diſſolved by the internal heat and moiſture, diffuſes its noxious vapours, which being received into the pores of the nervous membranes, their fluid, on which their tone and motion depend, loſes its nature: hence, the ſenſation and alſo the periſtaltic motion of the inteſtines become more languid: for if a ſtrong ſmell, as in the caſe of hyſterics, received up the noſtrils, ſuch for inſtance as proceeds from burnt feathers or aſſa-fætida, has ſo ſudden an effect in compoſing the turbulent and diſorderly motions in the nervous and membranous ſyſtem; and on the contrary, if a ſweet ſmelling vapour has the force of immediately diſturbing the whole frame of the muſcles by violent ſpaſms; why may not the foul and noiſome exhalations of narcotics, by contaminating a fluid of conſummate activity, as well injure or put a ſtop to its motion? But thoſe things which act on the nerves, are moſt ſpeedy in their effects, becauſe their influence is immediately diffuſed over the whole nervous ſyſtem.

Narcotics have alſo a mighty influence on the membranes of the brain, whereby greatly diminiſhing the ſpring and ſyſtole of the arteries, which are furniſhed with very thin membranes, they cauſe a ſtagnation of the blood therein,

therein, with diſtentions of the veſſels of the head, by which means they induce a torpor, drowſineſs, delirioulneſs, with frightful and troubleſome dreams. Though much miſchief and danger may be the natural effects of narcotics, ſo that they may be eſteemed not far removed from the nature of poiſons, phyſicians, however, both ancient and modern, have at all times experienced great benefit from hypnotic anodynes, eſpecially in violent pains and fluxes; for what greater benefit can we receive than to be delivered from intolerable pains? Beſides, ſuch is the nature of pain, that, if it be of any long continuance, it either weakens the powers of the mind and body to ſuch a degree, as to render a diſeaſe, otherwiſe favourable, eventually mortal, or elſe brings death of itſelf.

In diſorders of the ſtomach and inteſtines all things which induce a ſtupor, are very cautiouſly or never at all to be exhibited, becauſe no kind of medicines is ſo pernicious and injurious to the tone and motions of the nervous parts.

To preſerve health and prevent diſeaſes, nothing is ſo effectual, as to retain the tone, ſtrength, and motion of what they call the primæ viæ, or firſt paſſages, becauſe that moſt ſalutary excretion which is performed by ſtool, and diſcharges the ſordes, which are the recrements remaining after digeſtion, or are collected from all parts of the body, depends chiefly thereon. Where this evacuation is wholly ſuppreſſed, or performed after a ſlow and remiſs manner, a deluge of viſcous humours is ſoon collected, and becomes the cauſe as well as the fomenter of diſeaſes. Now there is nothing which ſo effectually diminiſhes the periſtaltic motion of the inteſtines, and ſuppreſſes inteſtinal excretion, as ſudatives and anodynes.

It is very dangerous to adminiſter opiates and anodynes where the ſtomach and inteſtines are inclining to an inflammation and ſphacelus, or where an extraordinary impurity of the humours diſpoſes them to a corruption.

NARDUS Celtica, Celtic nard, in botany, a ſmall ſpecies of valerian, with uncut, oblong, obtuſe, ſomewhat oval leaves. It is a native of the Alps, from whence the ſhops have been generally ſupplied with the dried roots, conſiſting of a number of blackiſh fibres, with the lower parts of the ſtalks adhering; which laſt are covered with thin yellow ſcales, the remains of the withered leaves.

This root has been recommended as a ſtomachic, carminative, and diuretic; at preſent it is ſcarcely otherwiſe made uſe of, in this country, than as an ingredient in mithridate and theriaca, though its ſenſible qualities promiſe ſome conſiderable medicinal powers. It has a moderately ſtrong ſmell, and a warm bitteriſh ſubacrid taſte, ſomewhat reſembling thoſe of common wild valerian: an extract made from it by rectified ſpirit has a ſtrong penetrating taſte, and retains in good meaſure the particular flavour, as well as the bitterneſs and pungency of the root.

Nardus Indica, Indian nard, or ſpikenard, in botany, the buſhy top of the root, or the remains of the withered ſtalks and ribs of the leaves of an Indian graſſy-leaved plant, of which we have no particular deſcription. The nard, as brought to us, is a congeries of ſmall tough reddiſh brown fibres, cohering cloſe together, but not interwoven, ſo as to form a bunch or ſpike about the ſize of a finger; ſometimes two or three bunches iſſue from one head, and ſometimes bits of leaves and ſtalks in ſubſtance are found among them.

The Indian nard, now kept in the ſhops chiefly as an ingredient in mithridate and theriaca, was formerly employed in the ſame intentions as the Celtic, and is ſaid to be uſed among the Orientals as a ſpice. It is moderately warm and pungent, accompanied with a flavour not diſagreeable.

NARRATION, in oratory and hiſtory, a recital or rehearſal of a fact as it happened, or when it is ſuppoſed to have happened.

Narration, in poetry, is uſed for the action, or event, that makes the ſubject of an epic poem.

NARWAL, in ichthyology, the unicorn fiſh, ſo called from a long wreathed tooth; though it be really a tooth fixed in the gomphoſis of the upper-jaw, altogether in the manner of other teeth: hence ſome have called it monodon, which is certainly a more proper name than that of the unicorn-fiſh.

The narwal is a fiſh of the whale kind, often growing to twenty-five feet in length, but is more commonly found from ſixteen to twenty.

NASIAS, in anatomy, a thin bone making the upper part of the noſe.

NATES, in anatomy, a term expreſſing thoſe two fleſhy exterior parts of the body, vulgarly called the buttocks.

Nates Cerebri, two circular protuberances of the brain, ſituated on the backſide of the medulla oblongata, near the cerebellum.

NATION, a collective term, uſed for a conſiderable people inhabiting a certain extent of land, confined within fixed limits, and under the ſame government.

NATIVE, a perſon conſidered as born in a certain place which was the proper reſidence of his parents, and where he received his education.

Native, or Nativus, in our ancient law books, ſignifies a perſon born in a ſtate of villainage, in contradiſtinction to a bondſman, or one who became a villain by his own act and deed.

NATIVITY, or Natal-Day, the day of a perſon's birth.

The word nativity is chiefly uſed in ſpeaking of the ſaints, as the nativity of St. John the Baptiſt, &c. But when we ſay the Nativity, it is underſtood of that of Jeſus Chriſt, or the feaſt of Chriſtmas. See the article Christmas.

Nativity, in aſtrology, the ſituation of the heavens, and particularly of the twelve houſes, at the moment of a perſon's birth.

NATRON, or Mineral Fixed Alkaline Salt. This ſalt is contained in great abundance in the waters of the ocean, and makes the baſis of the neutral ſalt ſo plentifully extracted from them for alimentary uſes. It is likewiſe diſcoverable in ſundry mineral ſprings, even of thoſe which do not participate of ſea-ſalt; and in ſome of the Eaſtern countries it is ſaid to be found in conſiderable quantities on the ſurface of the earth, ſometimes pure, but more commonly blended with various heterogeneous matters, from which it is extracted by means of water. The alkali, called ſoda, prepared by incinerating the maritime plant kali, or glaſs-wort, contains a ſalt of the ſame kind.

The mineral alkali agrees in its general qualities with the common lixivial ſalts of vegetables. The differences which have been obſerved are, that it is milder and leſs acrid in taſte: that when diſſolved in water, it concretes, on evaporation, into a cake, which appears a congeries of ſmall cryſtals: that when expoſed to the air, though it grows moiſt on the ſurface, it does not run into a liquid form: that the neutral ſalt reſulting from its coalition with the vitriolic acid, is very eaſily diſſoluble in water and fuſible in the fire: that with the nitrous acid it forms cubical cryſtals; and with the marine, perfect ſea ſalt. Its medicinal differences from the common lixivial ſalts, in pure ſtate, are not well known; but in combination with acids, they are apparent.

NATURAL, in general, ſomething that relates to nature. Natural children are thoſe born out of lawful wedlock.

The natural functions are thoſe actions whereby the aliments are changed and aſſimilated ſo as to become a part of the body.

Natural History, a deſcription of the productions of the earth, air, water, &c. See Earth, &c.

The natural hiſtory of any one place is a very extenſive ſubject, which, according to Mr. Boyle, may be conveniently reduced to four heads; viz. the things that regard the heavens, the air, the waters, and the earth.

Of the firſt claſs, are the longitudes and latitudes of places, the lengths of the longeſt and ſhorteſt days and nights; the climates, parallels, &c. what fixed ſtars are ſeen, and what are not ſeen there.

About the air may be obſerved, its temperature, as to the firſt four qualities, and the meaſure of them; its weight, clearneſs, and refractive power; its ſubtility or coarſeneſs; its abounding with or wanting an eſurient ſalt; its variations according to the ſeaſons of the year and the times of the day; what duration the ſeveral kinds of weather uſually have; what meteors it is moſt or leaſt ap

apt to breed; and in what order they are generated, and how long they generally laſt; what winds it is moſt ſubject to; whether any of them be ſtated or ordinary; what diſeaſes are ſaid to be epidemical, or depending on the ſtate and condition of the air; what other diſeaſes it is ſubject to, wherein the air may be ſuppoſed to have ſome ſhare; what is the uſual ſalubrity of it, and what ſort of conſtitutions it agrees with, what it does not. See the article AIR.

About the waters, it may be proper to obſerve the ſea, its depth, tides, currents, ſaltneſs, and other qualities: next the rivers will come under conſideration, their depth, length, courſe, inundation, and the goodneſs or badneſs of their waters, with their gravity, and other peculiar qualities; after theſe, the lakes, ſprings, ponds, &c. are to be conſidered, eſpecially the mineral waters, their kinds, qualities and virtues, and the manner of trying them: the inhabitants of the waters may follow here; and the particular kinds of fiſh that are found there, whether of the ſea or rivers, are to be mentioned, with an account of their ſtores, bigneſs, goodneſs, ſeaſons of perfection, haunts, peculiarities of any kind relating to them, and the manner of taking them, eſpecially when there is any thing ſingular in it.

The things relating to the earth, are laſt to be examined: theſe are, firſt the earth itſelf, then its inhabitants, and its various productions, whether external or internal. In the earth itſelf may be obſerved, its dimenſions, ſituation eaſt, weſt, north and ſouth; its figure; its plains and valleys, and their extent; its hills and mountains, and the height of the talleſt, both in reference to the neighbouring valleys and plains, and to the level of the ſea; as alſo whether the mountains lie ſcattered, or are diſpoſed in ridges; and if of the latter kind, whether they run eaſt, weſt, north, or ſouth. What promontories alſo, and what fiery or ſmoaking hills it has, if any: whether the country be coherent, or much broken into iſlands: what the magnetical declination is in ſeveral places, and the variation of that declination in the ſame place, and if thoſe be conſiderable; what may be conjectured as the occaſions of them, whether the vicinity of iron-mines, of ſubterranean fires, or what elſe. What the nature of the ſoil is, whether clayey, ſandy, or of good mould; and what vegetables, plants, and trees, beſt agree with it and ſucceed in it, what worſt. By what particular contrivances the inhabitants improve the advantages, or remedy the diſadvantages of the ſoil; and what hidden qualities the ſoil may have. The inhabitants of the earth are then to be conſidered, both natives, and ſtrangers that have been long ſettled there; and in particular, their ſtature, colour, features, ſtrength, agility, or defects of theſe; and their complexions, hair, beauty, and the like; their diet, inclinations and cuſtoms, ſo far as they are not owing to education; the fruitfulneſs and barrenneſs of the women; their hard or eaſy labours; the diſeaſes they are moſt ſubject to, and any remarkable ſymptoms attending them.

As to the external productions of the earth, the enquiries are to be theſe: what graſſes, grains and fruit it beſt produces: the herbs, flowers, and timber-trees; and the coppices, groves, foreſts and woods the country has or wants: what peculiarities are obſervable in any of them; what ſoils they moſt like or diſlike, and with what culture they thrive beſt. Then what animals the country has or wants, both as to wild beaſts and birds of prey, and as to poultry and cattle of all ſorts; and particularly, if they have any animals that are not common, or any thing particular in thoſe they have. After thoſe, the ſubterranean ſtores are to be examined; what minerals the earth affords, and what it wants; then what quarries of ſtone, and in what manner they lie: what clays and earths are found there; as clays, marles, fuller's earths, earths for tobacco-pipes, earths for potter's wares, medicinal earths; what other mineral productions it yields, whether coals, ſalt-mines, or ſalt-ſprings, alum, vitriol, ſulphur, &c. What metals the country yields, with a deſcription of the mines of them; their depths, numbers, ſituations, ſigns, waters, damps, quantities of ores, goodneſs of the ores, and the ways in uſe for the reducing them to metals.

NATURAL INCLINATIONS are the tendencies of our minds towards things ſeemingly good.

NATURAL PHILOSOPHY, that which conſiders the powers and properties of natural bodies, and their mutual actions on one another.

The buſineſs of natural philoſophy, ſays Boerhaave, is to communicate a ſolid and accurate knowledge of all the bodies in being, and all the affections thereof. Nor can this ſcience be acquired otherwiſe than by obſerving, by means of our ſenſes, all the objects which the Author of nature has made cognizable thereto: hence, the firſt and principal part of this ſcience is to collect all the manifeſt and ſenſible appearances of things, and reduce them into a body of natural hiſtory. Now there are two ways of making ſuch obſervations; the firſt, when we view things nearly as they happen to turn up, without any deſign or intervention of our own; in which way no great improvements can be expected in the art, becauſe chance having here the direction, only exhibits occaſional or extemporary properties: the other method is, when, after a thorough acquaintance with bodies, we apply them to other bodies equally known, diligently attending to the reſult, and obſerving whether any thing new ariſes. See EXPERIMENTAL PHILOSOPHY.

NATURAL, in muſic, is a term variouſly uſed: thus natural muſic is the ſame with vocal, in oppoſition to artificial muſic, or that performed on inſtruments. A ſong is alſo called natural, when its notes move eaſily and gracefully, the voice or inſtrument being nowiſe forced or ſtrained. Natural harmony is that produced by the natural and eſſential chord of the mode.

A natural note is uſed to contradict thoſe flats and ſharps that are ſet at the beginning of a ſtave; and in ſuch caſe, it muſt be taken exactly as in the gamut. For the character of this note, ſee the article CHARACTER.

NATURALIST, a perſon well verſed in the ſtudy of nature, and the knowledge of natural bodies, eſpecially in what relates to animals, vegetables, metals, minerals, and ſtones.

NATURALIZATION, in law, the act of naturalizing an alien, or placing him in the condition of a natural born ſubject.

NATURALS, *Res Naturales*, among phyſicians, whatever naturally belongs to an animal, in oppoſition to non-naturals. See the article NON-NATURALS.

NATURE, *Natura*, according to Mr. Boyle, has eight different ſignifications; it being uſed, 1. For the Author of nature, whom the ſchoolmen call *Natura Naturans*, being the ſame with God. 2. By the nature of a thing we ſometimes mean its eſſence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature, with what accrues to him by birth; as when we ſay, that ſuch a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we ſay, that a ſtone by nature falls to the earth. 5. Sometimes we underſtand by nature the eſtabliſhed courſe of things. 6. Sometimes we take nature for an aggregate of powers belonging to a body, eſpecially a living one; in which ſenſe phyſicians ſay, that nature is ſtrong, weak, or ſpent; or that, in ſuch and ſuch diſeaſes, nature left to herſelf will perform the cure. 7. Sometimes we uſe the term nature for the univerſe, or whole ſyſtem of the corporeal works of God; as when it is ſaid of a phœnix, or chimera, that there is no ſuch thing in nature. 8. Sometimes too, and that moſt commonly, we expreſs by the word nature a kind of ſemi-deity, or other ſtrange kind of being.

If, ſays the philoſopher, I were to propoſe a notion of nature, leſs ambiguous than thoſe already mentioned, and with regard to which many axioms, relating to that word, may be conveniently underſtood, I ſhould firſt diſtinguiſh between the univerſal and the particular nature of things. Univerſal nature I would define to be the aggregate of the bodies that make up the world, in its preſent ſtate, conſidered as a principle; by virtue whereof they act and ſuffer, according to the laws of motion preſcribed by the Author of all things. See BODY, INERTIA, MOTION, &c.

And this makes way for the other ſubordinate notion; ſince the particular nature of an individual conſiſts in the general nature, applied to a diſtinct portion of the univerſe; or, which is the ſame thing, it is a particular aſſemblage of the mechanical properties of matter, as figure, motion, &c.

Thoſe who deſire a more particular diſcuſſion of each of theſe opinions may conſult Boyle's Free Inquiry into the vulgar notion of nature.

NAVAL, relating to a ſhip; whence

NAVAL ARCHITECTURE, the art of deſigning the figure, forming the ſeveral limbs, and conſtructing the hull or lower-frame of a ſhip, diſtinct from the ſuper-ſtructure, which comprehends her machinery and furniture for ſailing, which laſt is explained under the articles MAST, SAILS, and RIGGING.

To whom the world is indebted for the invention of ſhips is, like all other things of equal antiquity, uncertain: if we liſten to the fables of the poets, we ſhall be extremely divided in our opinion amongſt the variety of competitors. Prometheus, Neptune, Janus, Atlas, Hercules, Jaſon, Danaus, Erythraeus, &c. appear with ſufficient authority to claim our aſſent: but Minerva, the auſpicious parent of arts and ſciences, ſeems to have a ſuperior title, and to her, probably with more propriety, it has been attributed by fame.

But ſome who reject theſe fabulous traditions, and pretend to greater certainty in their allegations, aſcribe it to the inhabitants of ſome places that border on the ſea, and ſeem appropriated by nature for harbouring ſhips, ſuch as the Phœnicians, Aeginenſians, &c. This difference of opinions appears naturally to have ariſen, on obſerving the various places where navigation was firſt practiſed, or from the different conſtruction and equipage of ſhips; ſome of which having been built by the abovementioned perſons, have entitled them to the whole invention.

A very ſmall portion of art or contrivance was ſeen in the firſt ſhips; they were neither ſtrong nor durable, but conſiſted only of a few planks laid together, without beauty or ornament, and juſt ſo compacted as to keep out the water. In ſome places they were only the hulks or ſtocks of trees hollowed, and then conſiſted only of one piece of timber; nor was wood alone applied to this uſe, but any other buoyant materials, as the Egyptian reed papyrus, or leather, of which the primitive ſhips were frequently compoſed; the bottom and ſides being extended on a frame of thin battens or ſcantlings, of flexible wood, or begirt with wickers, ſuch as we have frequently beheld amongſt the American ſavages ourſelves. In this manner they were often navigated upon the rivers of Ethiopia, Egypt, and Sabaean Arabia, even in later times. But in the firſt of them, we find no mention of any thing but leather or hides ſewed together. In a veſſel of this kind, Dardanus ſecured his retreat to the country afterwards called Troas, when he was compelled by a terrible deluge, to forſake his former habitation of Samothrace. According to Virgil, Charon's infernal boat was of the ſame compoſition.

But as the other arts extended their influence, naval architecture likewiſe began to emerge from the gloom of ignorance and barbariſm; and as the ſhips of thoſe ages were increaſed in bulk, and better proportioned for commerce, the appearance of thoſe floating citadels of unuſual form, full of living men, flying with ſeemingly expanded wings over the ſurface of the untravelled ocean, ſtruck the ignorant people with terror and aſtoniſhment: and hence, as we are told by Ariſtophanes, aroſe the fable of Perſeus flying to the Gorgons, who was actually carried thither in a ſhip! Hence, in all probability, the famous ſtory of Triptolemus riding on a winged dragon is deduced, only becauſe he ſailed from Athens, in the time of a great dearth, to a more plentiful country, to ſupply the neceſſities of his people. The fiction of the flying horſe Pegaſus may be joined with theſe, who, as ſeveral mythologiſts report, was nothing but a ſhip with ſails, and thence ſaid to be the offſpring of Neptune, the ſovereign of the ſea: nor does there appear any other foundation for the ſtories of griffons, or of ſhips transformed into birds and fiſhes, which we ſo often meet with in the ancient poets. So acceptable to the firſt ages of the world were inventions of this nature, that whoever made any improvements in navigation, or naval architecture, building new ſhips better fitted for ſtrength or ſwiftneſs than thoſe uſed before, or rendered the old more commodious by additional contrivances, or diſcovered countries unknown to former travellers, were thought worthy of the greateſt honours, and often aſſociated into the number of their deified heroes. Hence we have in aſtronomy the ſigns of Aries and Taurus, which were no other than two ſhips: the former tranſported Phryxus from Greece to Colchos, and the latter Europa from Phœnicia to Crete. Argo, Pegaſus, and Perſeus's whale, were likewiſe new ſhips of a different ſort from the former, which, being greatly admired by the barbarous and uninſtructed people of thoſe times, were tranſlated amongſt the ſtars, in commemoration of their inventors, and metamorphoſed into conſtellations by the poets of their own and of ſucceeding ages.

It will be neceſſary on this occaſion to ſay ſomething of the different parts uſed in fabricating the ſhips of the ancients, previous to an explanation of modern ſhip-building.

The ignorance of the principal parts of their ſhipping has occaſioned many miſtakes and much confuſion in thoſe who have converſed with authors of antiquity. Herein we ſhall chiefly follow Scheffer, who hath ſo copiouſly treated this ſubject, and with ſuch induſtry and learning, collected whatever is neceſſary to illuſtrate it, that very little room is left for enlargement by thoſe who incline to purſue this inveſtigation.

The chief parts then, of which ſhips formerly conſiſted, were three, viz. the belly, the prow, and the ſtern: theſe were again compoſed of other ſmaller parts, which ſhall briefly be deſcribed in their order.

1. In the belly or middle part of the ſhip there was τρόπις, *carina*, or the keel, which was compoſed of wood: it was placed at the bottom of the ſhip, being deſigned to cut and glide through the waves, and therefore was not broad, but narrow and ſharp; whence it may be perceived that not all ſhips, but only the μακραὶ, which ſhips of war were called, whoſe bellies were ſtraight, and of a ſmall circumference, were provided keels, the reſt having uſually flat-bottoms. Around the outſide of the keel were fixed pieces of wood to prevent it from being damaged, when the ſhip was firſt launched into the water, or afterwards ſtruck on any rocks; theſe were called χελεύσματα, in Latin *cunei*.

Next to the keel was φαλκὶς, the pump-well, or well-room, within which was contained the ἀντλία, or pump, through which water was conveyed out of the ſhip.

After this, there was δευτερὰ τρόπις, or the ſecond keel, ſomewhat reſembling what is now called the kelſon; it was placed beneath the pump, and called λεσβίον, χαλκήνη, κλειτοποιὸν: by ſome it is falſely ſuppoſed to be the ſame with φαλκὶς.

Above the pump was an hollow place, called by Herodotus κοιλη της νηὸς, by Pollux κυτος and γαστρὰ, becauſe large and capacious, after the form of a belly, by the Latins *teſtudo*. This was formed by crooked ribs, with which it was ſurrounded, which were pieces of wood riſing from the keel upwards, and called by Heſychius νομεὶς, and by others ἐγκοιλία, the belly of the ſhip being contained within them, in Latin *coſtæ*, and in Engliſh timbers: upon theſe were placed certain planks, which Ariſtophanes calls ἐντερωνείας, or ἐντερωνίδα.

Hence proceed we to the πλευραὶ, *latera*, or ſides of the ſhip, which encompaſſed all the former parts on both hands; theſe were compoſed of large rafters extended from prow to ſtern, and called ζωστῆρες, and ζωμιάματα, becauſe by them the whole fabric was begirt or ſurrounded.

In both theſe ſides the rowers had their places, called τοῖχοι, and ἑδώλια, in Latin *fori* and *tranſtra*, placed above one another: the loweſt was called θαλαμος, and thoſe that laboured therein θαλαμιοι; the middle ζυγὰ, and the men ζυγιοι; the uppermoſt θρανοι; whence the rowers were termed θρανῖται. In theſe apartments were ſpaces through which the rowers put their oars; theſe were ſometimes one continued vacuity from one end to the other, called τρῆρη, but more uſually diſtinct holes, each of which was deſigned for a ſingle oar; theſe were

were ſtiled τρηματα, τρυπηματα, as alſo οφθαλμοι, becauſe not unlike the eyes of living creatures: all of them were by a more general name termed εγκωτα, from containing the oars; but εγκωτιν ſeems to have been another thing, ſignifying the ſpaces between the banks of oars on each ſide, where the paſſengers appear to have been placed: on the top of all there was a paſſage or place to walk, called παραδος, and παραβρανος, as joining to the ξρανοι, or uppermoſt bank of oars.

2. Πρωρα, the prow or fore-deck, whence it is ſometimes called μετωπον, and commonly diſtinguiſhed by other metaphorical titles taken from human faces. In ſome ſhips there is mention of two prows, as alſo two ſterns; ſuch was Danaus's ſhip adorned by Minerva when he fled from Egypt. It was uſual to beautify the prow with gold and various ſorts of paint and colours: in the primitive times red was moſt in uſe, whence Homer's ſhips were commonly dignified with the titles of μιλτοπαρηοι, and φοινικοπαρηοι, or red-faced: the blue likewiſe or ſky-colour was frequently made uſe of, as bearing a near reſemblance to the colour of the ſea, whence we find ſhips called by Homer κυανοπρωροι, by Ariſtophanes κυανεμβολοι. Several other colours were alſo made uſe of; nor were they barely varniſhed over with them, but very often annealed by wax melted in the fire, ſo as neither the ſun, winds, nor water, were able to deface them. The art of doing this was called from the wax κηροζυραφια, from the fire εγκαυσικη, which is deſcribed by Vitruvius, and mentioned in Ovid.

Picta coloribus uſtis
Caeruleam matrem concava puppis habet.

The painted ſhip with melted wax anneal'd
Had Tethys for its deity.——

In theſe colours the various forms of gods, animals, plants, &c. were uſually drawn, which were likewiſe often added as ornaments to other parts of the ſhips, as plainly appears from the ancient monuments preſented to the world by Bayſius.

The ſides of the prow were termed πτερα, or wings, and παρια, according to Scheffer, or rather παρειαι; for ſince the prow is commonly compared to an human face, it will naturally follow that the ſides ſhould be called cheeks; theſe are now called bows by our mariners.

3. Πρυμνη, the hind-deck or poop, ſometimes called ουρα, the tail, becauſe the hindmoſt part of the ſhip: it was of a figure more inclining to round than the prow, the extremity of which was ſharp, that it might cut the waters; it was alſo built higher than the prow, and was the place where the pilot ſat to ſteer: the outer-bending part of it was called στεγεων, anſwering to our term, quarter.

They had various ornaments of ſculpture on the prow; as helmets, animals, triumphal wreaths, &c. The ſtern was more particularly adorned with wings, ſhields, &c. Sometimes a little maſt was erected whereon to hang ribbands of divers colours, which ſerved inſtead of a flag to diſtinguiſh the ſhip, and a weather-cock to ſignify the part from whence the wind blew. See COLOURS, FLAG, SIGNAL.

On the extremity of the prow was placed a round piece of wood, called the αμυχις, from its bending; and ſometimes οφθαλμος, the eye of the ſhip, becauſe fixed on the fore-deck; on this was inſcribed the name of the ſhip, which was uſually taken from the figure painted on the flag. Hence comes the frequent mention of ſhips called Pegaſi, Scyllæ, Bulls, Rams, Tigers, &c. which the poets took the liberty to repreſent as living creatures that tranſported their riders from one country to another.

The whole fabric being compleated, it was fortified with pitch, and ſometimes a mixture of roſin, to ſecure the wood from the waters; whence it comes that Homer's ſhips are every where mentioned with the epithet of μελαιναι, or black. The firſt that made uſe of pitch were the inhabitants of Phaeacia, ſince called Corſica: ſometimes wax was employed in the ſame uſe, whence Ovid,

Caerulea ceratas accipit unda rates.

The azure waves receive the waxy ſhips.

After all, the ſhip being bedecked with garlands and flowers, the mariners alſo adorned with crowns, ſhe was launched into the ſea with loud acclamations and other expreſſions of joy; and being purified by a prieſt with a lighted torch, an egg and brimſtone, or after ſome other manner, was conſecrated to the god whoſe image ſhe bore.

Originally all ſhips, for whatever uſe deſigned, appear to have been of the ſame form; but the various purpoſes of navigation ſoon occaſioned a conſiderable difference in their ſize, conſtruction and equipage, at which time they became chiefly characterized as veſſels of war, burthen, or paſſage.

The ſhips of war of the ancients were diſtinguiſhed from other kinds of veſſels, by various turrets and acceſſions of building, ſome to defend their own ſoldiers, and others to annoy the enemy; and from one another, in later ages, by ſeveral degrees or ranks of oars, the moſt uſual number of which was four or five, which appear not to have been arranged, as ſome imagine, on the ſame level in different parts of the ſhip; nor yet, as others have ſuppoſed, directly above one another's heads; but their ſeats being placed one behind another, aſcended gradually like ſtairs. Ptolomy Philopater, urged by a vain-glorious deſire of exceeding all the world beſides in naval architecture, is ſaid to have farther enlarged the number of banks to forty, and the ſhip being otherwiſe in equal proportion, this raiſed her to ſuch an enormous bulk, that ſhe appeared at a diſtance like a floating mountain or iſland, and, upon a nearer view, like a prodigious caſtle on the ocean: ſhe contained four thouſand rowers, four hundred ſailors employed in other ſervices, and near three thouſand ſoldiers. But this, and all ſuch monſtrous fabrics, ſerved only for ſhew and oſtentation, being rendered by their vaſt bulk unwieldy and unfit for ſervice. Athenaeus informs us, the common names they were known by, were Cyclades, or Aetna, i. e. iſlands, or mountains, to which they ſeemed nearly equal in bigneſs; conſiſting, as ſome report, of as many materials as would have compoſed fifty triremes, or ſhips of three banks. Thus much we thought neceſſary to ſay concerning the naval architecture of the ancients; for the ſeveral ornaments, furniture, and inſtruments of war, ſee Scheffer, or Potter's Antiq. b. ii. c. 14, 15, 16, &c. To this we ſhall add, a general ſketch of the art, as it has been improved by the moderns, and appears at this day. See NAVIGATION, SHIP.

With regard to modern naval architecture, we think it neceſſary to obſerve here, that it is ſo complicated, extenſive, and various, comprehending ſuch a diverſity of ſtructures, that to treat the ſubject at large with accuracy and preciſion would fill a large volume of itſelf, and therefore greatly exceed our bounds; and being thus neceſſitated to contract our deſcription, we ſhall reſt ſatisfied with giving our readers a general idea of the principles of the art, the neceſſary qualities of a ſhip, and a deſcription of the principal members that compoſe this noble machine, in which we ſhall decline as much as poſſible to diſtract their imagination by leading them into a labyrinth of technical terms, from which we can neither extricate them nor ourſelves.

Naval architecture then ought to be reduced to the examination of three different queſtions; 1. thoſe which determine the figure of a ſhip; 2. thoſe which contribute moſt to her ſolidity; 3. thoſe which beſt facilitate her plans; that is, 1. her figure or outward form ought to be ſuitable to the ſervice for which ſhe is deſigned; 2. the exact ſhape of all the pieces of timber neceſſary to compoſe ſuch a fabric ſhould be found; 3. convenient apartments ſhould be made for the artillery, ammunition, proviſions, and cargo; together with ſuitable accommodations for the officers and men.

In order to give the bottom a proper figure, all the qualities neceſſary to make her anſwer the ſervice for which ſhe is deſigned ſhould be conſidered.

A ſhip of war ſhould carry her lower tier of guns four or five feet out of the water. A ſhip for the merchant-ſervice ſhould ſtow her cargo well; and be ſo faſhioned as to go well, carry a good ſail, ſteer eaſily, and lie in a high ſea without ſtraining.

Some eminent geometricians have endeavoured to diſcover the form of a ſolid that will anſwer all theſe purpoſes beſt, or meet with the leaſt reſiſtance in dividing the

the fluid through which it is to paſs; but have not been able to reduce their theory to practice, on account of the various ſituations in which a ſhip is obliged to lie when under ſail. The artificers thus deſpairing to eſtabliſh this point by mathematical rules, have applied themſelves entirely to experience and obſervation, which may greatly ſupply the deficiency of art; but though they may diſcover that a ſhip has bad qualities, it may be difficult to determine where they lie, or whether they are in the hull or rigging; but if their obſervations be aided by mathematical principles, it will certainly conduce very much to attain the deſired end. See EVOLUTION, TRIM, SAILING.

But as many ſhips have been built, which ſeem to anſwer every purpoſe for which they were calculated, ſome builders have ſtudied chiefly to copy thoſe which are approved by the ſeamen; and this method they very improperly regard as the principal rule to be obſerved in building. Now as the bodies of ſhips are very different, there are of courſe variety of different models adopted as ſtandards. But admitting a poſſibility to diſcover ſuch a body as ſhould give entire ſatisfaction, and have every good quality requiſite for the ſervice propoſed, yet this could by no means be eſtabliſhed as a ſtandard for ſhips of a different ſize to be copied from, ſince although we may have a firſt rate of 100 guns, which has been found by experience to be a very good ſhip in every reſpect; yet we ſhould be much deceived to build a 20 gun-ſhip, in which all the parts bore a ſimilar proportion to one another, which they have in the firſt rate.

It has been remarked above, that a ſhip of war muſt carry her loweſt tier of cannon high enough above the water, otherwiſe a great ſhip which cannot open her lower battery, when ſailing with a freſh ſide wind, may be taken by a ſmall one that can make uſe of her cannon.

A ſhip ſhould be duly poiſed, ſo as not to dive or pitch heavily, but go ſmooth and eaſy through the water, riſing to the waves when they run high, and the ſhip has reduced her ſail to the ſtorm; otherwiſe they will break aboard and ſtrain the decks, or carry away the boats: the maſts are likewiſe in great danger from the ſame cauſe.

A ſhip ſhould ſail well when large and before the wind, but chiefly cloſe hauled, or with a ſide wind, and her ſails ſharp trimmed, and then not fall off to the leeward.

Now the great difficulty lies in uniting ſo many different qualities in one ſhip, which ſeems to be nearly impoſſible; the whole art therefore conſiſts in forming the body in ſuch a manner that none of theſe qualities ſhould be entirely deſtroyed, and in giving a preference to that which is chiefly required in the particular ſervice for which the veſſel is deſigned: we ſhall briefly ſhow the poſſibility of uniting them all in one ſhip, that each of them may be eaſily diſcerned: when it happens otherwiſe the fault muſt lie in the builder, who has not applied himſelf to ſtudy the fundamental rules and principles of his art.

To make a ſhip carry a good ſail. A flat floor-timber, and ſomewhat long, or the lower-futtock pretty round, a ſtraight upper-futtock, the top-timber to throw the breadth out aloft; at any rate to carry her main breadth as high as the lower-deck. Now if the rigging be well adapted to ſuch a body, and the upper-works lightened as much as poſſible, ſo that they all concur to lower the center of gravity, there will be no room to doubt of her carrying a good ſail.

To make a ſhip ſteer well, and anſwer the helm quickly. If the faſhion-pieces be well formed, the tuck, or ſpreading-parts under the ſtern carried pretty high, the midſhip-frame well-forward, a conſiderable difference in the draught of water abaft more than afore, a great rake forward and none abaft, a ſnug quarter-deck and fore-caſtle; all theſe will make a ſhip ſteer well. A ſhip which ſails well, will certainly ſteer well.

To make a ſhip carry her guns well out of the water. A long floor-timber, and not of great riſing; a very full midſhip-frame, and low tuck, with light upper-works.

To make a ſhip go ſmoothly through the water without pitching hard. A long keel, a long floor, not to riſe too high afore and abaft; but the area or ſpace continued in the fore-body, according to the reſpective weights they are to carry; all theſe are neceſſary to make a ſhip go ſmoothly through the water.

To make a ſhip keep a good wind, and drive little to the leeward. A good length by the keel; not too broad, but pretty deep in the hold, which will occaſion her to have a ſhort floor-timber, and a great riſing.

As ſuch a ſhip will meet with great reſiſtance in the water going over the broadſide, and little when going ahead, ſhe will not fall much to the leeward.

Now ſome builders imagine it is impoſſible to make a ſhip carry her guns well, bear a good ſail, and be a prime ſailer; becauſe it would require a very full bottom to gain the firſt two qualities, whereas a ſharp ſhip will anſwer better for the latter; but when it is conſidered that a full ſhip will carry a great deal more ſail than a ſharp one, a good artiſt may ſo form the body, as to have all theſe three good qualities, and alſo ſteer well. After what has been ſaid on this, it certainly cannot be thought impoſſible to unite all theſe different qualities in one ſhip: giving the water a proper curve, ought likewiſe to be conſidered, upon which the beauty and ſtatelineſs of a ſhip greatly depend; ſince it is this which makes a ſhip look airy and graceful in the water. There is no certain rule for laying them down; this is left entirely to the fancy and taſte of the artiſt, which, as we have more than once obſerved, is not often of the moſt delicate degree, or corrected by truth and judgment; witneſs the barbarous and unnatural mixture of Gothic and Chineſe ornaments, "clumſy heroes and fat-headed gods," on the ſame ſhip, the monſtrous iſſue of a ſavage conception and way-ward genius, as deformed and perverſe as their own cant-timbers.

As we cannot without greatly exceeding our limits treat particularly of all the pieces that compoſe a ſhip, we have here defined all the principal pieces, and laid down each piece ſeparately (plate XCI.), by which means the length of the ſcarfs are deſcribed, and the manner in which they are joined together.

Explanation of Plate XCI.

A. The keel, in four pieces, to be firmly bolted together and clinched.

I. The fore-foot, one end of which is ſcarfed to the fore-end of the keel, of which it is a part, and the other end makes a part of the ſtem, to which it is ſcarfed.

u u. Two pieces of dead-wood, one afore and the other abaft, fayed upon the keel.

C. C. The ſtem in two pieces to be ſcarfed together: it is the circular piece of timber where both the ſides of the ſhip unite forward.

E E. The apron, in two pieces, to be ſcarfed together, and fayed on the inſide of the ſtem, to ſupport the ſcarf of the ſtem: for which purpoſe the ſcarf of the apron muſt be clear from that of the ſtem.

o. The ſtemſon in two pieces, to ſupport the ſcarf of the apron.

o. The falſe poſt, which is fayed to the fore-part of the ſtern poſt. Faying is fitting two pieces of wood, ſo as that one may be joined to the back, or inſide of the other, ſo as to lie cloſe.

B. The ſtern-poſt: it is tenanted into the keel, to which it is faſtened with a knee; and is that ſtraight piece of timber at the after-end of the ſhip, into which both the ſides are united.

D. The back of the poſt, which is likewiſe tenanted into the keel, and ſecurely bolted to the ſtern-poſt; the deſign of it is to give ſufficient breadth to the poſt, which ſeldom can be procured of a ſufficient breadth in one piece.

F. The knee which faſtens the poſt to the keel.

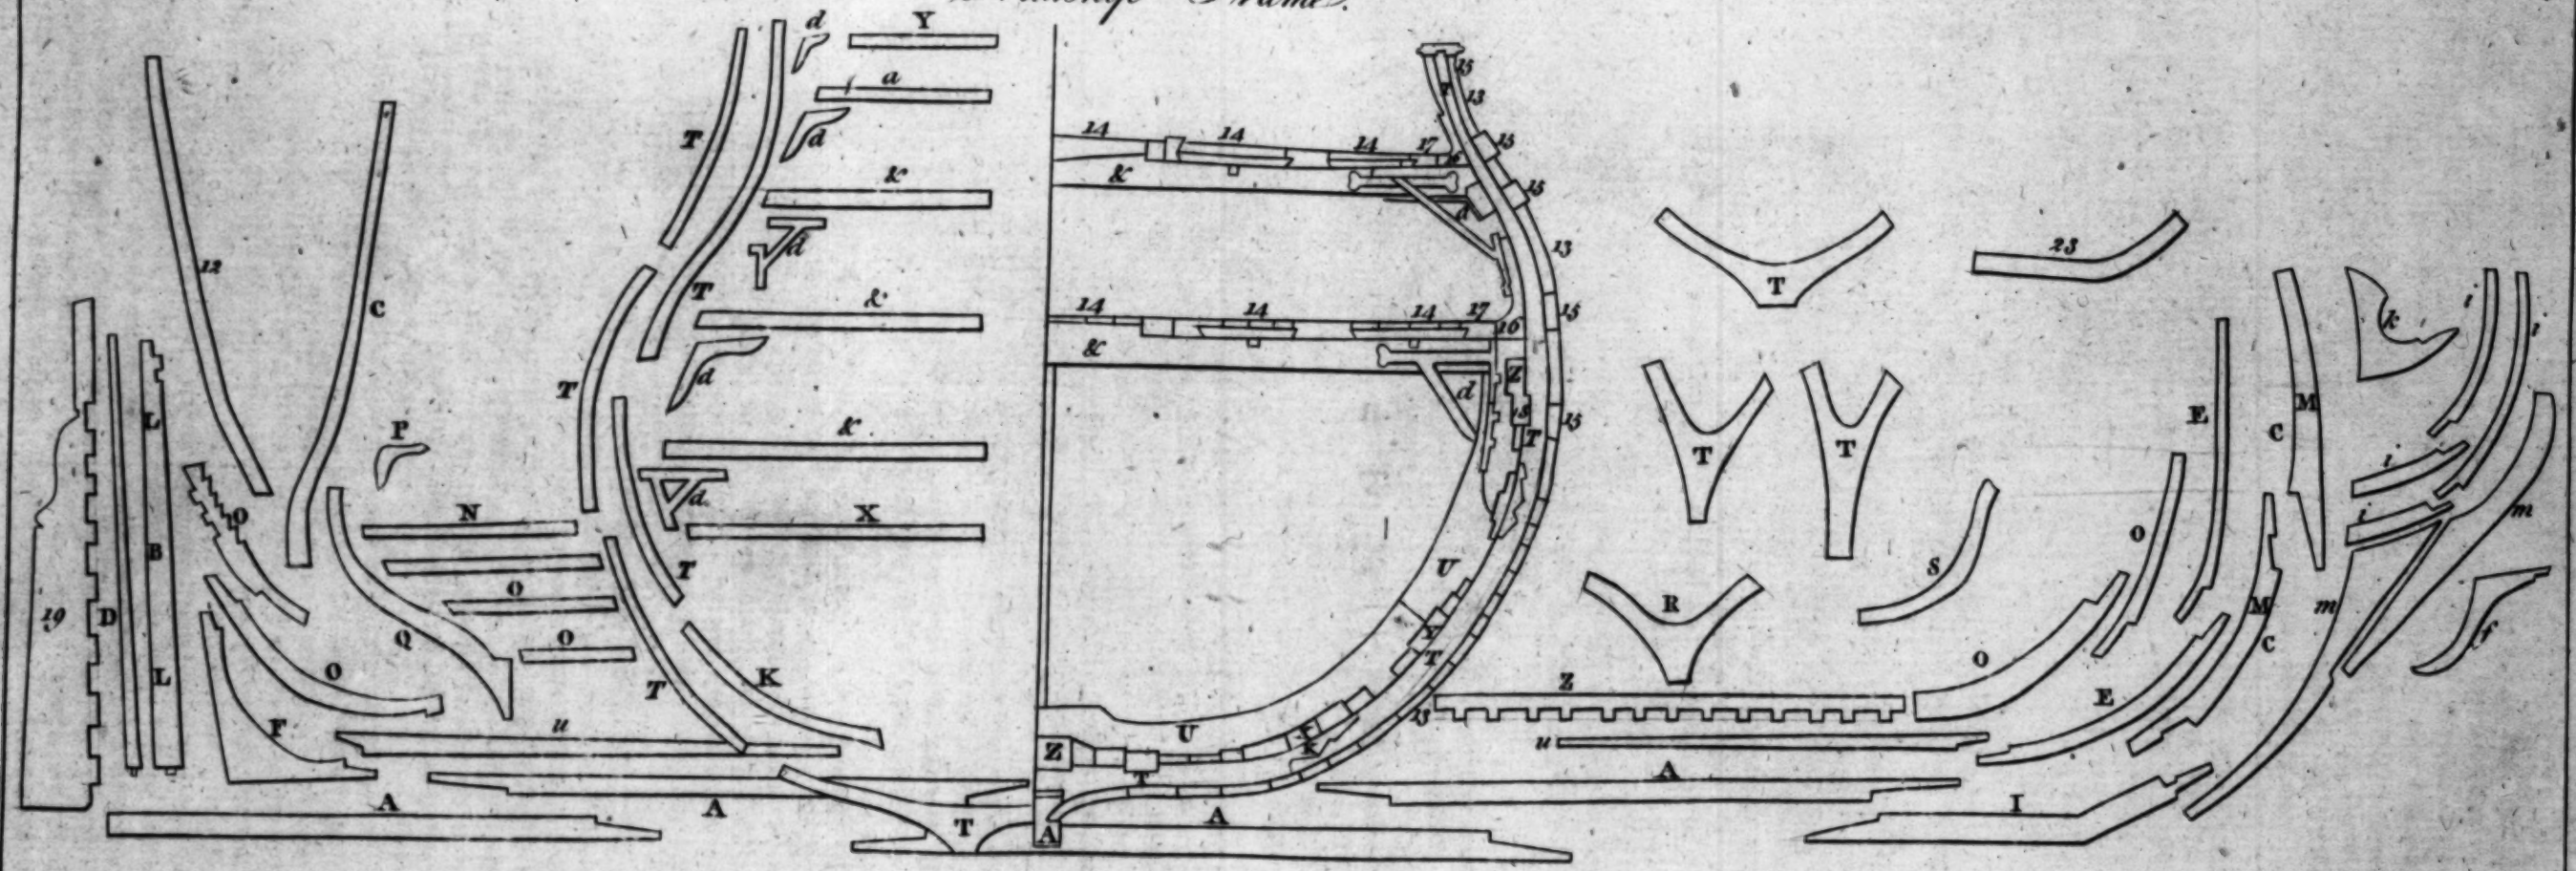
N. The wing-tranſom. It is fayed acroſs the ſtern-poſt, and bolted to the head of it: the faſhion-pieces are faſtened to the end of it; under this, and parallel to it, is the deck tranſom.

O O. Two tranſoms faſtened to the ſtern-poſt and faſhion-pieces, in the ſame manner as the wing-tranſom.

P. The tranſom-knee which faſteneth it to the ſhip's ſide.

Q. The faſhion-piece, of which there is one on each ſide: their heels are faſtened to the ſtern-poſt, at the height of the floor-ribbands, and their heads are faſtened to the wing-tranſom.

Midship Frame.



5 JA 59

T. A floor-timber: it is fayed acroſs the keel, to which it is faſtened by a bolt through the middle.

TTTTT. 2d, 3d, 4th futtocks and top-timbers. Theſe ſhew the proper length and ſcarf of the timbers, in what is called the midſhip-frame, which is a plane comprehended between the two ſides, at their extreme breadth, and the keel to which it is perpendicular; ſo that if a ſhip were cut through perpendicular to her length, and at her greateſt breadth, the exterior and interior part of both ſides from the upper-parts or edges, called the gunnels, down to the keel, would exhibit the midſhip-frame. The futtocks are to be joined, to complete a frame of timbers.

U U. Riders: theſe are fayed on the inſide of the ſhip acroſs the keel, and ſtand in the ſame manner as the timbers, and conſiſt of floor and futtock riders.

Z. The kelſon: this is made of two or three large pieces of timber ſcarfed together in the ſame manner as the keel. It is placed over the middle of the floor timbers, and ſcored about an inch and a half down upon each of them.

R, S. Breaſt-hooks: theſe are fayed on the inſide acroſs to the ſtem, and to the bow on each ſide of it, to which they are faſtened with proper bolts. There are generally four or five in the form of an R in the hold, one in the form of S, into which the lower-deck planks are rabbetted; there is one right under the hawſe-holes, and another under the ſecond deck.

X, Y, Z. Are thick planks which are fayed to the inſide, and ſtretch fore and aft, or from one end of the ſhip to the other, to ſupport the ſcarfing of the timbers.

Z. Are thick planks in the inſide called clamps, which ſuſtain the end of the beams.

15, 15, 15, 15, 15. Are the wales: they are planks broader and thicker than the reſt, which are faſtened to the outſide of the ſhip on a line with the decks: with regard to the planks reaching from the wale upwards to the top of the ſide, and downwards to the keel, the reader is referred to the ſection of one half of the midſhip-frame, as laid down in the plate.

d, d, d, d, d, d, d. Are knees. Theſe are crooked pieces of timber conſiſting of two arms, which form an angle ſometimes acute and ſometimes obtuſe or rectangular: their uſe is to faſten any two pieces together; as the beams to the ſhip's ſide, &c.

19. The rudder: this is joined to the ſtern-poſt by the rudder-irons, upon which it turns round in the googings, which are faſtened upon the ſtern-poſt for that purpoſe. There is a mortiſe cut through the head of it, into which a long bar is fitted, called the tiller, by which the rudder is turned from one ſide to the other, and both parts together, are called the helm.

23. The cat-heads. Theſe are two large ſquare pieces of timber, one on each ſide of the bowſprit: they project from the bow over the ſide, in order to keep the anchor clear of the ſhip, which is drawn up by a rope called the cat-fall, which paſſes through certain pullies, called ſheaves, in the outer-end of the cat-head: their inner-ends are faſtened upon the fore-caſtle.

m, m, i, i, i. Are the ſeveral pieces which compoſe the knee of the head, called by ſeamen the cut-water; the lower part *m* is fayed to the ſtem, the heel of it is ſcarfed to the head of the fore-foot; it is faſtened to the bows by two knees, called cheeks, and to the ſtem by a knee called a ſtandard, in the form of a K.

a, X, Y. Are beams, or large pieces of timber which ſupport the planks of each deck. See the article BEAMS. The reader will readily diſcover that the two ſides of the midſhip-frame in the middle of the plate are ſo diſpoſed, that all the pieces on one ſide may be ſeen before they are joined, and on the other after they are fixed in their proper places.

In ſhips of war the general dimenſions are eſtabliſhed by the authority of thoſe appointed by the government for that purpoſe. In the merchants ſervice, the extreme breadth, length of the keel, depth in the hold, and height in the waſte, and between decks; and ſometimes the height and breadth of the wing-tranſom, are agreed on by contract: and from theſe dimenſions the builder is to form a draught ſuitable to the trade for which ſhe is deſigned.

The firſt thing to be done, in order to lay down the deſign of a ſhip of war, is to determine the length, which ſhould be either on the lower-gun deck, or at the load-water-line: water-lines are deſcribed lengthways on a ſhip's bottom by the ſurface of the water in which ſhe ſwims; that which determines how much ſhe is under water when laden, is called the load-water-line, which is commonly at, or a little below her extreme length: there muſt be great care that ſufficient room be left between the ports.

The next thing is to eſtabliſh the breadth by the midſhip-beam; although ſome builders are divided in their opinion, about proportioning this to the length, yet moſt of them conform to dimenſions of ſhips of the ſame rate. After theſe two dimenſions are determined, the depth of the hold muſt be fixed, which in moſt ſhips is half the breadth; but the form of the body ſhould be conſidered; for a flat floor will require leſs hold than a ſharp one. The diſtances between the decks muſt alſo be determined.

We may then proceed to fix the length of the keel, which will oblige us to eſtabliſh the rake of the ſtem and ſtern-poſt: rake is the difference between a ſhip's length at the keel and upper-deck: or the line on which ſhe gradually projects farther out with the ſtem and ſtern as the fabric riſes. The height of the ſtem and wing-tranſom muſt alſo be fixed.

After theſe dimenſions are ſettled, the timbers may be conſidered which form the ſides of the ſhip. A frame of timbers, which appears to be one continued timber, is compoſed of one floor-timber, two or three futtocks, and a top-timber on each ſide: all theſe being united and ſecured by croſs-bars, form a circular incloſure; that which incloſes the greateſt ſpace is called the midſhip-frame: the curve of this frame is inverted at the lower part, ſo that the floor-timber will be ſomewhat hollow in the middle, whereby the ends will form a very obtuſe angle; but this angle decreaſes, the farther the frames are removed from the midſhips, in ſuch a manner, that the foremoſt and aftmoſt will become very ſharp, and form a very acute angle. Floor-timbers of this kind are called crutches.

Builders differ much in determining the ſtation of the midſhip-frame, ſome placing it before, and others at the middle of the ſhip. Thoſe who place it before alledge, that if a ſhip is full forward, ſhe will meet with no reſiſtance after ſhe has once opened a column of water, and that the water ſo diſplaced will eaſily unite abaft, and by that means force the ſhip forward, and have more power on the rudder, the farther it is from the center of gravity; and beſides this, comes neareſt the form of fiſhes, which ſhould ſeem to be the moſt advantageous for dividing fluids.

When the riſing of the midſhip floor-timber is agreed on, we may then proceed to decide the riſing line of the floor abaft on the ſtern-poſt, and afore on the ſtem.

The height of the lower-deck is the next thing to be conſidered: it is determined in midſhips by the depth of the hold; and ſome builders make it no higher than the ſtem, but they raiſe it more than it is in the midſhips, by as much as the load-water-mark abaft exceeds that afore. As to the height between decks, it is altogether arbitrary, and muſt be determined by the rate of the ſhip, and the ſervice ſhe is deſigned for.

We come now to conſider the upper-work, or all that is above water, called the dead work; and here the ſhip muſt be narrower; ſo that all the weight, lying above the load-water-line, will thereby be brought nearer the middle of the ſhip; by which means ſhe will ſtrain leſs by working the guns, &c. But though theſe advantages are gained by narrowing a ſhip above water, great care muſt be taken not to narrow her too much, for there muſt be ſufficient room upon the upper deck for the guns to recoil. The ſecurity of the maſts ſhould likewiſe be remembered, which requires ſufficient breadth to ſpread the ſhrouds, although this may be in ſome meaſure ſupplied by enlarging the breadth of the channels which ſpread them.

With regard to naval architecture, if we except ſome ancient artificers poſſeſſed of a natural genius, and a few of the moderns who have been inſtructed in the principles of geometry, and have laboured hard to make a progreſs

in ſhip-building, we may venture to aſſert that the greateſt number ſatisfy themſelves with copying ſhips that are eſteemed good ſailers; and a tenacious imitation of theſe ſervile mechanical methods, which are too common, have, to the great reproach of the art, produced all theſe pretended rules of proportion; for the various models they have hitherto uſed, prove beyond diſpute that they have not yet found a proper ſtandard: the only reaſon why they have tried ſo many different methods, is becauſe they could not find the beſt; yet every builder confines theſe mechanical rules of deſcribing the midſhip-frame, and forming the reſt of the timbers, to his own fancy, concealing it from the inferior artificers, who may be poſſeſſed of a genius and taſte greatly ſuperior to his own; but we would inform theſe gentlemen, that this is ever regarded by the polite world as a certain characteriſtic of a narrow and vulgar education, a ſordid and illiberal diſpoſition, and a perverſe and crooked taſte!

Whoever heard, that a great architect endeavoured to conceal the proportions of the different orders of architecture? Do we not ſee every where ſyſtems of that noble art publiſhed, plans, elevations, and ſections, preſented to the general obſervation of mankind for their approbation or cenſure? But poſſibly, we are afraid that publication of ſhip-building may be dangerous in a political light, by making our enemies maſters of the ſecret. This can never be the caſe, ſince we know that our ſeventy-gun ſhips and frigates, generally eſteemed the moſt uſeful ſhips in the navy, have been all the late war entirely copied from the models of the French, who have never ſtudied to conceal them. But although the methods of deſcribing the midſhip-frame, and forming the reſt of the timbers, be known to moſt of our younger artificers, yet we have but few good maſter-builders; this requires a greater portion of genius, than the mere mechanical methods. They ſhould, at leaſt, have a ſufficient acquaintance with mathematics, phyſics, mechanics, and the nature of ſolids and fluids, to be able to diſcover what figure would procure ſome good quality, without hazarding the putting a bad one in its place.

We refer ſuch readers as wiſh to be more fully or particularly informed of ſhip-building to M. Du Hamel's curious and uſeful Elements of Naval Architecture, to which we acknowledge ourſelves greatly indebted for the above deſcription. Mr. Mungo Murray has alſo publiſhed a book on this ſubject, called a Treatiſe on Ship-Building, &c. which muſt be of great ſervice to the younger artificers of this profeſſion, as it contains variety of very accurate drawings of ſhips. An abridgment of M. Du Hamel's book referred to above, is alſo tranſlated, and annexed to Murray's Treatiſe.

NAVAL-ARMAMENT, the ſame with fleet of ſhips of war, which ſee.

NAVAL-CAMP, in antiquity, a fortification, conſiſting of a ditch and parapet on the land-ſide, or a wall built in the form of a ſemi-circle, and extended from one point of the ſea to another. This was ſometimes defended with towers, and beautified with gates, thro' which they iſſued forth to attack their enemies. Homer hath left us a remarkable deſcription of the Grecian fortifications of this ſort, in the Trojan war, beginning at v. 436. Iliad η. of which we ſhall preſent our readers with Mr. Pope's tranſlation.

> Then to ſecure the camp and naval powers,
> They rais'd embattled walls with lofty tow'rs:
> From ſpace to ſpace were ample gates around,
> For paſſing chariots, and a trench profound,
> Of large extent; and deep in earth below
> Strong piles infix'd ſtood adverſe to the foe.

Towards the ſea, or within it, they fixed great pales of wood, like thoſe in their artificial harbours; before theſe the veſſels of burthen were placed in ſuch order, as that they might be inſtead of a wall, and give protection to thoſe within; in which manner Nicias is reported by Thucydides to have encamped himſelf: but this ſeems only to have been practiſed when the enemy was thought ſuperior in ſtrength, and raiſed great apprehenſions of danger in them. When their fortifications were thought ſtrong enough to defend them from the aſſaults of enemies, it was frequent to drag their ſhips to ſhore, which the Greeks called ἑλκειν, the Romans *ſubducere*. Around the ſhips the ſoldiers diſpoſed their tents, as appears every where in Homer; but this ſeems only to have been practiſed in winter, when their enemy's fleet was laid up and could not aſſault them, or in long ſieges, and when they lay in no danger from their enemies by ſea, as in the Trojan war, where the defenders of Troy never once attempted to encounter the Grecians in a ſea-fight.

The adjacent places were uſually filled with inns, and ſtews, well ſtocked with females, that proſtituted themſelves to the mariners, merchants, and artificers of all ſorts, who flocked thither in great numbers; this however appears to be only in times of peace. *Potter's Antiquities of Greece.*

NAVAL-CROWN, *Corona Navalis*, in Roman antiquity. See the article CROWN.

NAVAL ENGAGEMENT implies in general either a ſea-fight between ſingle ſhips or fleets of men of war, or gallies, &c.

Before we enter into a deſcription of our modern naval engagements, it may perhaps be thought neceſſary to ſay ſomething of the manner in which the ancient ſhips of war entered into action, as alſo to give ſome account of their principal inſtruments of war, which gun-powder has rendered uſeleſs, and which time has almoſt buried in oblivion.

Εμβολον, *roſtrum*, was a beak of wood, fortified wih braſs, whence it is called χαλκωμα νεων, in Diodorus; and ſhips have ſometimes the epithet of χαλκεμβολοι: one or more of theſe was always faſtened to the prow, to annoy the enemy's ſhips, and the whole prow was ſometimes covered with braſs to guard it from rocks and aſſaults. The perſon who firſt uſed theſe beaks is ſaid to have been one Piſaeus, an Italian; for it will not be allowed that the primitive Grecians had any knowledge of them, ſince no ſuch thing is mentioned in Homer, which could ſcarcely have happened had they been invented at the time of the Trojan war. Theſe beaks were at firſt long and high, but afterwards it was found more convenient to have them ſhort and firm, and placed ſo low as to pierce the enemy's ſhip under water.

Καταστρωματα Σανιδωματα, an elevation of wood, raiſed on the deck on purpoſe for the ſoldiers, that they might level their miſſive weapons with greater force and certainty againſt their enemies. In the primitive ages, particularly about the time of the Trojan war, we are told by Thucydides, that the ſoldiers uſed to fight upon the foremoſt and hindermoſt decks; and therefore, whenever we find Homer ſpeak of ικρια νηος, which his ſcholiaſts interpret hatches, we are only to underſtand him of theſe eminences.

There were alſo commonly hides, or ſuch like materials hung on both ſides of the ſhip, as well to hinder the waves from falling into it, as to receive the darts caſt from the adverſe ſhips, that under theſe, as walls on both ſides, the ſoldiers might without danger annoy their enemies.

Δελφιν, a certain machine, which being uſually a part of theſe ſhips, cannot be omitted in this place: it was a vaſt and maſſy piece of lead or iron, caſt in the form of a dolphin, and hung with cords and pullies to the ſail-yards or maſt, whence being thrown with great violence into the adverſe ſhips, either penetrated them, and ſo opened a paſſage for the riſing floods, or by its weight and force ſunk them to the bottom of the ſea.

Δορατα ναυμαχα, ſpears of an unuſual length, ſometimes exceeding twenty cubits, whence they are called in Livy *haſtæ longæ*, and by Homer, in his 15th Iliad, ξυστα ναυμαχα, and μακρα, where Ajax in reſiſting Hector,

> A pond'rous mace with ſtuds of iron crown'd,
> Full twenty cubits long he ſwings around.
>
> POPE.

Δρεπανον, called by Appian δρεπανιδιον, by Diodorus δρεπανηφορον χειριον, was an engine of iron, crooked like a ſickle, and fixed to the top of a long pole, wherewith they cut aſunder the cords of the ſail-yards, and thereby

by letting the ſails fall down, diſabled the light ſhips. Not unlike this was another inſtrument, armed at the end with a broad iron head, edged on both ſides, wherewith they cut the cords that tie the rudder to the ſhip.

Κερκιδες were machines to caſt ſtones into the enemy's ſhips.

We find another engine mentioned by Vegetius, which hung upon the main-maſt, and reſembled a battering-ram; for it conſiſted of a long beam, and head of iron, and was with great violence puſhed againſt the ſides of adverſe ſhips.

Χειρ σιδηρα, in Latin, *manus ferrea*, was a grappling-iron, which they caſt out of an engine into the enemy's ſhip. It is ſaid to have been firſt uſed in Greece by Pericles the Athenian; at Rome by Duilius. Different from theſe were the αρπαγες, *Harpagines*, ſaid to be invented by Anacharſis the Scythian philoſopher; which, as Scheffer collects out of Athenaeus, were hooks of iron hanging on the top of a pole, which being ſecured with chains to the maſts, or ſome other lofty part of the ſhip, and then caſt with great force into the enemy's veſſel, caught it up into the air. The means uſed to defeat thoſe engines, was to cover their ſhips with hides, which caſt off, or blunted the ſtroke of the iron.

The ancient Greeks, in preparing for an engagement at ſea, made it their firſt buſineſs to diſburthen their ſhips of war of all proviſions, and other lumber not neceſſary in the action, leſt by too heavy a load they ſhould be rendered unwieldy, and unfit for ſervice, being neither able with force and vigour to aſſail their enemies, nor by lightly tacking about to avoid their onſets. This done, when the enemy appeared in view, they took down their ſails, lowered their maſts, and ſecured whatever might expoſe them to the winds, chuſing rather to be governed by oars, which they could manage at their pleaſure.

As to their order of battle, that was varied as time, place, and other circumſtances required; being ſometimes formed like an half-moon, and called σολος μηνοειδης, the horns jutting out towards the enemy, and containing the ableſt men and ſhips; ſometimes, on the contrary, having its belly neareſt the enemy, and its horns turned backwards, whence it was termed κυρτη παραταξις: nor was it unuſual to range them in the form of a circle, which they called κυκλον τιθεναι; or, to mention no more, in the figure of the letter V, with the horns extended in a direct line, and meeting at the end; which order was named εμβολη παραταξις; in Latin, *foreeps*; and was uſually encountered by the enemies ranged into the ſame order inverted, whereby they reſembled the figure of a wedge or beak, whence it was called *cuneus* or *roſtrum*; this enabled them to penetrate into the body of the adverſe battle.

Before they joined battle, both parties invoked the gods to their aſſiſtance by prayers and ſacrifices; and the admirals going from ſhip to ſhip in ſome of the lighter veſſels, exhorted their ſoldiers in a ſet oration, to behave themſelves like men: then, all things being in readineſs, the ſignal was given by hanging out of the admiral's galley a gilded ſhield, as we read in Plutarch; or a red garment or banner, which was termed αιρειν σημεια. During the elevation of this the fight continued, and by its depreſſion, or inclination towards the right or leſt, the reſt of the ſhips were directed in what manner to attack their enemies, or retreat from them. To this was added the ſound of trumpets, which was begun in the admiral's galley, and continued round the whole navy. It was likewiſe uſual for the ſoldiers, before the fight, to ſing a pæan, or hymn, to Mars; and after the fight, another to Apollo.

The fight was uſually begun by the admiral-galley, as we find done at the battle of Salamis, and another time by Attalus's ſhip: it was carried on in two different manners, for not only the ſhips engaged one another, and by their beaks and prows, and ſometimes their ſterns, endeavoured to daſh in pieces, or overſet and ſink their oppoſers, but the ſoldiers alſo annoyed their enemies with darts and ſlings; and upon their nearer approach, with ſwords and ſpears. Thus Lucan:

Ut primum roſtris crepuerunt obvia roſtra,
In puppim rediere rates, emiſſaque tela
Æra texerunt vacuumque cadentia pontum.

The ſhips firſt meeting ſhew their fierceſt rage,
And furiouſly with claſhing beaks engage;
Theſe turn about, and then the javelins fly,
And ſhow'rs of arrows darken all the ſky;
The ſea is cover'd o'er.——

We find by the ſame author, that after this firſt onſet, their ſhips approached ſo near each other as to be linked together with chains or grappling-irons, and then they fought with ſword in hand. Sometimes for want of irons they ſo fixed their oars, as thereby to hinder their enemies from retreating; ſo we read in Lucan:

Seque tenent remis, toto ſtetit æquore bellum.

The ſhips they hold with oars, and all around
The face of horrid war appears.——

This ſort of combat was not unlike a ſiege, where the ſtronger party, prevailing over their enemies, entered their veſſels by laying bridges between them, and having killed, or taken priſoners, all they found in arms, ſeized and dragged away their ſhips.

When a town was beſieged by ſea, they uſed to environ its walls and harbour with ſhips, ranged in order from one ſide of the ſhore to the other, and ſo cloſely joined together by chains and bridges, on which armed men were placed, that, without breaking their order, there could be no paſſage from the town to the ſea; this leaguer Diodorus calls ζευγμα. The better to prevent any attempts of the beſieged, Demetrius is ſaid to have invented a ſort of boom armed with ſpikes of iron, which ſwam upon the waters; this he placed at the mouth of the harbour of Rhodes, when he beſieged that city. Sometimes they blocked up the harbour, or made a paſſage to the town by raiſing a vaſt mole before it, as we read of Alexander in the ſiege of Tyre; or by ſinking ſhips filled with ſtones and ſand, as we find practiſed by the Romans.

The attacks were uſually carried on by men ſtanding upon bridges between the ſhips, and thence with darts and ſtones forcing the beſieged from their walls: thus Alexander, in the ſiege of Tyre, ſo ordered his gallies, that two of them being joined at the heads, and the ſterns ſomewhat diſtant, boards and planks were laid over in the faſhion of bridges, for ſoldiers to ſtand upon, who were in this manner rowed cloſe to the wall, where, without any danger, they threw darts at their enemies, being ſheltered behind the fore-decks of their own gallies. Here, alſo, that they might throw their miſſive weapons with greater advantage, and batter the walls with their rams and other engines, they erected towers ſo high as to command the city walls, from which having repelled the defenders, they by this means had opportunity to deſcend by ladders.

The beſieged were not at a loſs for ways of defeating theſe ſtratagems; the ſhips linked together they pulled aſunder with iron-hooks, the paſſage to the town they blocked up in the ſame manner the enemies had done that of the harbour, or otherways; if they could not hinder their approach, they failed not to gall them with darts, ſtones, fire-balls, melted pitch or metals, and many other things; and, laſtly, to trouble you no farther, it was frequent for thoſe in the town to deſtroy the veſſels and works of the beſiegers by fire-ſhips, as we find done by the Tyrians, who, taking a large veſſel, put a great quantity of ballaſt into the ſtern, covered the head with pitch, tar, and brimſtone, then by the help of ſails and oars brought her cloſe to the Macedonian fortreſs, where having ſet the combuſtible matter on fire, they retreated into boats prepared for that purpoſe; the fire immediately ſeized the towers of the fortification, and by the help of torches and fire-brands caſt by thoſe in the boats, the work itſelf took fire, and that vaſt pile, on which ſo much time and labour had been beſtowed, was in a few moments quite demoliſhed. The uſe of fire-ſhips we likewiſe meet with amongſt the Rhodians in Diodorus the Sicilian.

We have obſerved above that the ancients ranged their ſhips or gallies ſo as to preſent them in front to their enemy; becauſe the machines they then made uſe of, were fixed

fixed in the heads or prows of their veſſels: the ſame reaſon now prevails with regard to the gallies, which are drawn up in the form of a creſcent, or half-moon, whoſe ends or horns are oppoſed to the enemy; in the middle of which is the admiral, from whence he the more diſtinctly obſerves the motions of his fleet throughout. The two fleets being thus drawn up, approach each other to a convenient diſtance, when the battle beginning at the ends of the half-moon, extends inſenſibly till the whole fleet is engaged, and each partakes of the danger and glory of the action. See lower compartment of plate XCII.

In an engagement of ſhips of war, the fleets are drawn up in two parallel lines upon a wind. The ſhips keep cloſe to the wind on the line they are formed in, and are commonly at a cable's length diſtance one from the other; the fire-ſhips, tranſports, tenders, &c. keeping at half a league diſtance on the oppoſite ſide of the enemy. Thus in the upper compartment of plate XCII. the fleets A B and C D, that are engaged, are ranged under an eaſy ſail, cloſe to the wind; and the fire-ſhips E E, of the fleet A B, are to windward; the fire-ſhips F F, are to the leeward of their fleet C D. This form was obſerved, for the firſt time, in the famous battle of the Texel, where the duke of York defeated the Dutch, on the 13th of June, 1665. See the article SQUADRON and LINE.

It is probably the moſt expedient method, as proved by experience, to keep a conſtant cannonade on the enemy, by firing in platoons, which will have a much greater effect, and diſtreſs them more, than the common received notion of broad-ſide and broad-ſide with ſome intervals between, which is generally the caſe in moſt actions; in order to which, it will be moſt prudent to divide the guns into five fires, in the following manner, viz. half the guns abaft below, then half the guns abaft aloft, ſo the other half below forward; and, laſtly, the quarter-deck guns, and thoſe on the fore-caſtle: ſo that, by the time your firſt platoon is fired, you will be able to keep up a conſtant fire on your enemy, which method is preferable, as was obſerved before, to broad-ſide and broad-ſide, where chance has often a greater ſhare in the execution than judgment; notwithſtanding, this laſt method is ſometimes neceſſary, as time and circumſtances may offer. It is likewiſe neceſſary to point your guns ſo as to make a breach in your enemy's ſhip.

The chief judgment of an admiral, is to form his line in a proper diſpoſition and ſtrength from the van throughout to the rear; in doing which, particular care muſt be had to make the center ſtrong, for if that is forced, or broke through, the battle is looked upon as loſt. Here it is to be obſerved, that, in a ſea-action, the center is made the ſtrongeſt, whereas in a land-fight it is the weakeſt; and the wings of an army are ſtrongeſt, leſt the enemy, by forcing a wing, ſhould have the advantage of flanking, and conſequently putting the line in diſorder: for the ſame reaſon alſo, the van and rear of a fleet is not put into confuſion, becauſe care is taken to make them proportionably ſtrong to reſiſt the enemy: therefore the weakeſt part of the line will be in the quarters, ſupported each way from the center throughout.

The ſignal being made for battle, each diviſion, every captain crouds into his proper ſtation without loſs of time: they endeavour to approach each other till within point-blank gun ſhot, which is near enough for a line of battle; for if you ſhould be too near, your line will naturally fall into a curve, notwithſtanding all your endeavours to the contrary; beſides, you cannot ſo well obſerve your own line: the enemy may intercept your ſight, eſpecially if the line be long, which may cauſe a miſtake in the ſignals. It would be better for the contending admirals in chief, that each had a view of his own line, as well as of that of the enemy, in order to make proper ſignals, and, if any diſtreſs happen, to be the better able to relieve, or if any advantage, to improve upon it.

The battle being begun, the fate of war decides the day. In a word, the ſucceſs of all depends upon placing your ſhot well, and preſerving a proper diſpoſition in the line. There is one maxim, by which we ſhould always be guided, that is, that bravery and reſolution are abſolutely neceſſary in the firſt ſort of engagement, viz. between ſingle ſhips; and conduct and bravery in the ſecond ſort, viz. that between two ſquadrons.

Conduct and preſence of mind are chiefly requiſite in a line of battle; for the admiral cannot be ſuppoſed to want bravery and reſolution. It is then he muſt ſummon up all his knowledge and experience, to judge of the ſtrength of his line; when and how to keep it as complete as poſſible, by ordering ſhips from the corps-de-reſerve, or by changing ſhips from one part of the line to the other; or by detaching from one part of the wings, which may not be ſo much preſſed, to that which is. Here he muſt alſo conſider the poſition of his enemy; his eyes muſt be on him, as well as on his own line, from the van to the rear; and all ſhould ſtrictly mind the admiral's motions, ſignals, &c. Boats will, in all probability, be continually paſſing from the ſhips to their flag-officers, if any thing extraordinary ſhould happen, to acquaint them of it; and from the admirals or commanding officers of each diviſion to the admiral in chief, giving an account of the ſtate and condition of each diviſion, which will be a great ſatisfaction to him, as he will then be better able to judge how to aſſiſt where moſt wanted when occaſion requires, or how to improve upon any advantage gained.

The battle drawing to a concluſion, it is eaſy to judge what the conqueror will do to improve his victory; as neceſſary a part of an officer as any in the action, as it requires great judgment and readineſs of thought; and the other, in making his retreat, ſhould let ſlip no opportunity to ſave as many of his fleet as he poſſibly can. His eye muſt be quick, and his judgment and preſence of mind as ready as at the firſt onſet of the battle. He has no other reſource leſt but in his eſcape, and this comfortable alleviation of his defeat, that a glorious retreat may gain him as much honour as the victory did to the conqueror. See the article RETREAT.

NAVAL FURNITURE. See ANCHORS, CABLES, CANNON, RIGGING, SAILS, &c.

NAVAL OFFICER. See the articles CAPTAIN, LIEUTENANT, MASTER, BOATSWAIN, GUNNER, and OFFICERS.

NAVE, in architecture, the body of a church, where the people are diſpoſed, reaching from the balluſter, or rail of the choir, to the chief door.

Some derive the word nave from ναὸς, a temple; and others from *navis*, a ſhip, by reaſon the vault or roof of a church bears ſome reſemblance to a ſhip.

NAVEL, *Umbilicus*, in anatomy. See the article UMBILICUS.

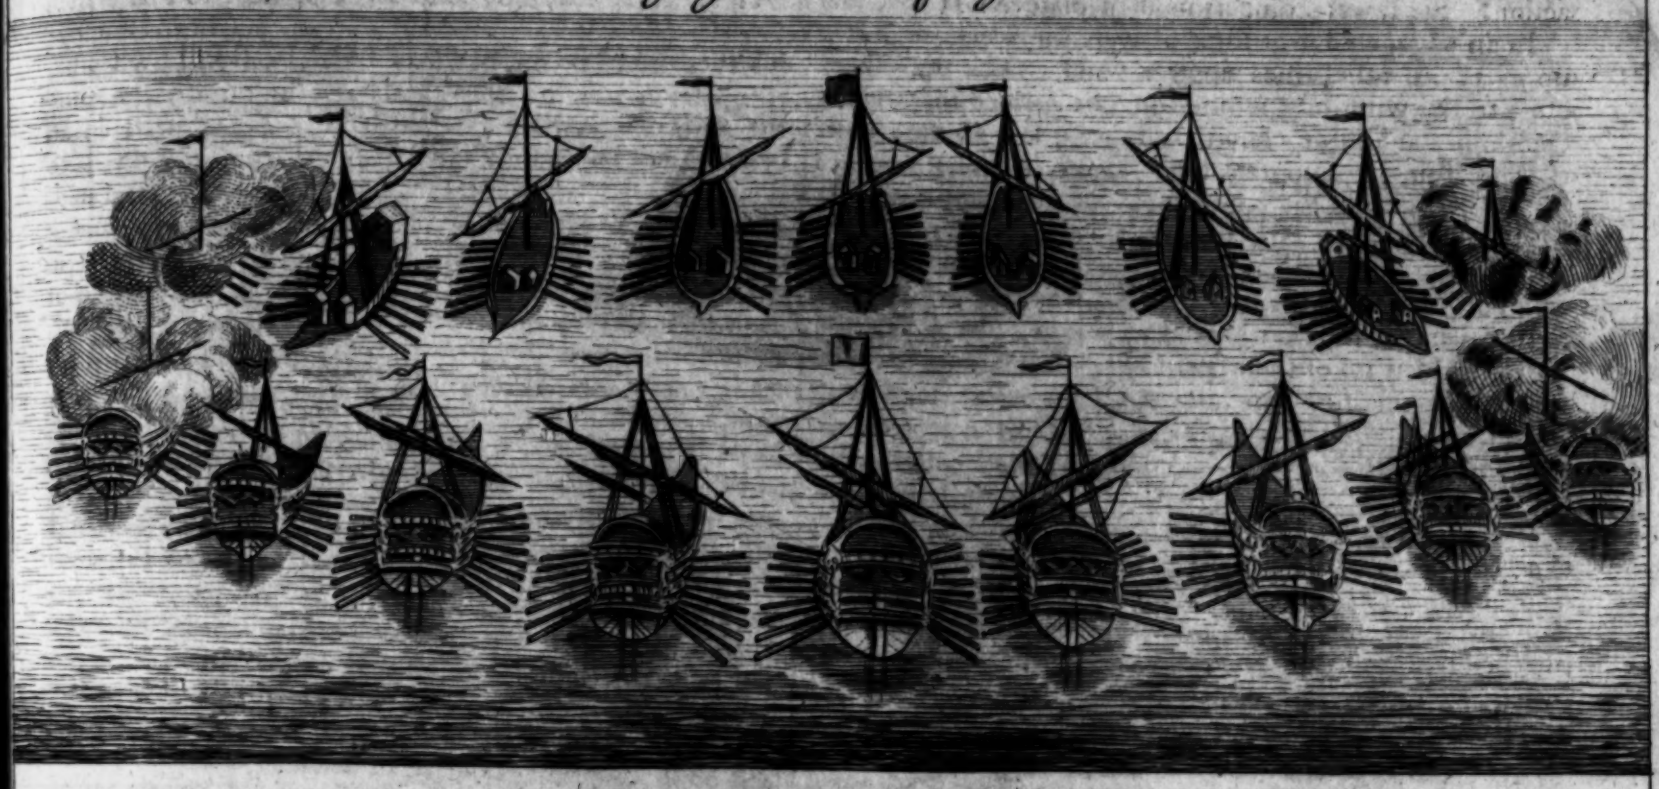
NAVEL-WORT, cotyledon, in botany. See the article COTYLEDON.

NAVEW, *Napus*, in botany, a plant of the turnip kind, with oblong roots growing ſlenderer from the top to the extremity. Two ſorts of it, ranked among the articles of the materia medica, are ſuppoſed by Linnæus to be only varieties, and are therefore joined into one ſpecies, under the name of braſſica radice cauleſcente fuſiformi. They are both biennial.

NAVEW, *Napus Sativa*, garden or ſweet navew, or French turnip; cultivated for the culinary uſe of its roots, which are warmer and more grateful than thoſe of the common turnip, and are ſaid to afford likewiſe, in their decoctions, a liquor beneficial in diſorders of the breaſt. The ſeeds, in figure roundiſh and in colour reddiſh, are the part principally directed for medicinal purpoſes: they have a moderately pungent taſte, ſomewhat approaching to that of muſtard ſeed, of the virtues of which they appear to partake: with muſtard ſeed they agree alſo in their pharmaceutic properties, their pungent matter being taken up completely by water and only partially by rectified ſpirit, and being diſſipated in the inſpiſſation of the watery infuſion, only an unpleaſant bitteriſhneſs remaining in the extract. As the navew ſeeds nearly ſimilar in kind to thoſe of muſtard, are apparently much inferior in degree, the college of Edinburgh has diſcarded them, and that of London retains them only as an ingredient in theriaca.

NAVEW, *Napus Silveſtris*, wild navew or rape, growing on dry banks and among corn, with leaves ſomewhat different from thoſe of the former, being more like thoſe

Engagement of Gallies.



Engagement of Ships of War.

5 JA 59

thoſe of cabbages than of turnips; the root ſmaller, and of a ſtronger unpleaſant taſte; and the ſeeds alſo rather more pungent, on which account they are preferred by the faculty of Paris. The ſeeds of both kinds yield upon expreſſion a large quantity of oil: the oil called rape-oil is extracted from the ſeeds of the wild ſort, which is cultivated in abundance, for that uſe, in ſome parts of England. The cake, remaining after the expreſſion of the oil, retains, like that of muſtard, the acrimony of the ſeeds. See the article RAPE-SEED.

NAVICULARE Os, in anatomy, a bone of the foot, lying between the aſtragalus and oſſa cuneiformia, and ſo called from its reſemblance to a boat.

It has a glenoid cavity, for its articulation with the head of the aſtragalus; and its anterior faces are received into the ſinuſes of the oſſa cuneiformia.

NAVIGATION, the theory and art of conducting a ſhip by ſea, from one port to another, or of diſpoſing and actuating her machinery, by the force of the wind, ſo as to begin and continue her motion at ſea.

Moſt of thoſe uſeful arts and admirable inventions which are the very ſupport of mankind, and ſupply them with all the neceſſaries and conveniences of life, have at firſt been the production of ſome lucky chance, or from ſlight and contemptible beginnings have been, by long experience, cautious obſervations, and various improvements, matured and brought to perfection. Inſtances of this kind are every where frequent and obvious, but none can be produced more remarkable than in the art of navigation, which, although now arrived to a pitch of perfection beyond moſt other arts, by thoſe ſucceſsful additions it has received from almoſt every age of the world, was in the beginning ſo mean and imperfect, that the pleaſure or advantage of thoſe who firſt applied themſelves to it, was very ſmall and inconſiderable.

Thoſe who adventured to commit themſelves to the liquid element, made their firſt eſſays in ſhallow waters, cautious of truſting themſelves at any conſiderable diſtance from the ſhore; but being emboldened by repeated trials, proceeded farther by degrees, till at length they took courage and launched forth into the main ocean. To this purpoſe Claudian ſays,

Inventa ſecuit primus qui nave profundum,
Et rudibus remis ſolicitavit aquas;
Tranquillis primum trepidus ſe credidit undis,
Littora ſecuro tramite ſumma legens;
Mox longos tentare ſinus, et linquere terras,
Et leni coepit pandere vela Noto:
Aſt ubi paulatim praeceps audacia crevit,
Cordaque languentem dedicere metum,
Jam vagus irrupit pelago, coelumque ſecutus,
Aegeas hyemes Ionaſque domat.

Which we may thus tranſlate:

Who launch'd the firſt bold veſſel on the deep,
And bade his aukward oars the waters ſweep;
Cautious, adventur'd on the margin-wave
At firſt; afraid the diſtant ſurge to brave:
Advancing farther, to the powerful gale,
High on the maſt he ſpread the ſwelling ſail.
Till by degrees he wander'd from the ſhore,
Unconſcious of thoſe fears he felt before;
And guided by ſome ſtar's auſpicious ray,
His bark undaunted cleav'd the watery way,
Along the Aegean and Ionian ſeas.

The officers appointed to ſuperintend the navigation of thoſe ſhips, were firſt,

Αρχικυβερνητας, the chief pilot, or pilot-general, who was entruſted with the care and management of all marine affairs, to provide commodious harbours, to direct the courſe of the fleet, and order all things concerning it, except thoſe which related to war. Second,

Κυβερνητης, the maſter or pilot, who had care of the ſhip, and government of the ſeamen therein, and ſat at the ſtern to ſteer. All things were managed according to his direction; it was therefore neceſſary that he ſhould have obtained a perfect knowledge of the art of navigation, which was called κυβερνητικη τεχνη, and chiefly conſiſted in theſe three things: Firſt, In the right management of the rudder, ſails, and all the engines uſed in navigation: Secondly, In the knowledge of the winds and celeſtial bodies, their motions and influences: Thirdly, In the knowledge of commodious harbours, of rocks, quick-ſands, and other occurrences of the ſea. How much this employment is ſimilar to the duty of the officer who manages the navigation in our ſhips of war, the reader will find in the article MASTER.

As to the heavenly bodies, they were obſerved by ſailors on a two-fold account, being of uſe to them in prognoſticating the ſeaſons, and as guides to ſhape their courſe. The principal of thoſe uſed in foretelling, were Arcturus, the Dog-ſtar, Arae, Orion, Hyades, Hoedi, Caſtor and Pollux, Helena, &c. It was likewiſe cuſtomary to take notice of various omens offered by ſea-fowls, fiſhes, and divers other things, as the murmuring of the floods, the ſhaking and buzzing noiſe of trees in the neighbouring woods, the daſhing of the billows againſt the ſhore, and many more, in which all good pilots were nicely ſkilled. As to the direction in their voyage, the firſt practitioners in the art of navigation, being unacquainted with the reſt of the celeſtial motions, ſteered all the day by the courſe of the ſun; at night betaking themſelves to ſome ſafe harbour, or reſting on the ſhore, and not daring to venture to ſea till their guide was riſen, to diſcover their way: that this was their conſtant cuſtom, may be obſerved from the ancient deſcriptions of thoſe times. See Virg Aen. 3. v. 508, *Sol ruit interea, et montes umbrantur opaci*, &c.

Afterwards the Phœnicians, called by ſome the firſt inventors of navigation, diſcovered the motions of ſome other ſtars, as may be obſerved by Pliny and Propertius. The Phœnicians we find to have been directed by Cynoſura, or the leſſer bear-ſtar, which was firſt obſerved, as ſome are of opinion, by Thales, the Mileſian, who was originally a Phoenician, when the mariners of Greece, as well as other nations, ſteered by the greater bear: for the firſt obſervation of this, they were obliged to Nauplius, if we may believe Theon, or according to the report of Flaccus to Tiphys, the pilot of the famous ſhip Argo. But of theſe two we are told by Theon, the former was the ſecurer guide, and therefore was followed by the Phoenicians, who, for ſkill in marine affairs, outſtript not only all the reſt of the world, but even the Grecians themſelves.

That the oars might ſtrike the water, and proceed in a regular and conſtant motion, keeping due time with each other, they had Τερπαυλης, a muſician, who, by the harmony of his voice and inſtrument, not only directed the rowers in their motions to ſtrike uniformly, but raiſed their ſpirits when weary with labour and ready to faint, as we read in Statius, Thebaid, v. 342.

Acclinis malo mediis interſonat Orpheus
Remigiis tantoſque jubet neſcire labores.

Againſt the maſt the tuneful Orpheus ſtands,
Plays to the weary rowers, and commands
The thought of toil away——

There were alſo people employed to ſet the ſhip along, and ſound the depths of the water with long poles, eſpecially in the night. This practice is very frequent amongſt the Poles at this time.

After they had invoked the protection of their gods by ſolemn prayers and ſacrifices, which, as they offered to other deities, ſo more eſpecially to thoſe who had any concern or command in the ſea; to the winds and tempeſts, the whole train of marine gods and goddeſſes, but above all to Neptune, they ſpread ſail and put to ſea. Nor was it enough for themſelves alone to petition the gods for ſafety and ſucceſs, but all the multitudes that thronged on theſe occaſions to the ſhore, earneſtly recommended them to the divine protection, and joined their fervent prayers for their deliverance from all the dangers they were going to encounter. Since the great improvement of navigation, theſe practices have, however, been intirely laid aſide by the moderns.

This done, we are told by the Scholiaſt upon Apollonius, that it was uſual to let fly a dove, which no doubt was looked on as an omen of ſafe return, becauſe that bird is not eaſily forced to relinquiſh its habitation, but when driven away delights to return. Then they put to ſea, the ſignal being given by a ſhout, by ſound of trumpet, and ſeveral other ways. In the night it was uſually given by torches lighted in the admiral-galley.

The ſhips were uſually ranged in this order; in the front went the lighter veſſels; after theſe followed the men of war, led on by the admiral, which was commonly diſtinguiſhed from the reſt by the richneſs of her ornaments: laſt of all, the veſſels of burthen came up. If the winds were high, or the ſea dangerous, they were extended at length, ſailing one by one; but at other times they went three or more in a breaſt. See the article NAVAL.

Tyre, the capital of the Phoenicians, whoſe commerce, riches, and power, are repreſented in ſuch lofty terms, both in ſacred and prophane authors, being furniſhed with excellent wood for ſhip-building, was very ſoon miſtreſs of a numerous fleet, with which the inhabitants conſtantly embarking on new expeditions, and ſettling new trades, they ſoon arrived at an incredible pitch of opulency and populouſneſs; inſomuch as to be in a condition to ſend out colonies, the principal of which was that of Carthage; which keeping up the Phoenician ſpirit of commerce, in time not only equalled Tyre itſelf, but vaſtly ſurpaſſed it, ſending its merchant-fleets through Hercules's pillars, now the ſtreights of Gibraltar, along the weſtern coaſts of Africa and Europe, and, if we may believe ſome authors, to America itſelf; the diſcovery whereof, ſo many ages afterwards, has been ſo glorious to the Spaniards.

After the deſtruction of Tyre, by Alexander the Great, its navigation and commerce were transferred to Alexandria, a new city, admirably ſituated for thoſe purpoſes, and propoſed for the capital of the empire of Aſia, which Alexander then meditated. And thus aroſe the navigation of the Egyptians, afterwards ſo cultivated by the Ptolomies, that Tyre and Carthage, which laſt, after having a long time diſputed empire with the Romans, was at length ſubdued, were quite forgot.

Egypt being reduced itſelf into a Roman province, after the battle of Actium, its trade and navigation fell into the hands of Auguſtus, in whoſe time Alexandria was only inferior to Rome; and the magazines of the capital of the world were wholly ſupplied with merchandize from the capital of Egypt.

At length Alexandria itſelf underwent the fate of Tyre and Carthage; and the fall of Rome and its empire drew along with it not only that of learning and the polite arts, but that of navigation; the Barbarians, into whoſe hands it fell, contenting themſelves with the ſpoils of the induſtry of their predeceſſors.

Navigation thus travelled, together with the polite arts, to the eaſtward; but it does not appear which of the European nations, after the ſettlement of their new maſters, firſt betook themſelves to navigation and commerce. Some think it began with the French, though the Italians ſeem to have the juſteſt title to it, and are accordingly looked on as the reſtorers thereof, as well as the other arts and ſciences, which had been baniſhed together, when the empire was torn aſunder: but at preſent the Britiſh navy holds an undiſputed empire over the main.

NAVIGATION, among the moderns, comprehends either the art of ſeamanſhip, or of conducting a ſhip by the laws of geometry, upon the wide and trackleſs ocean, or both.

By ſeamanſhip we would be underſtood to comprehend a perfect knowledge, as well of all the various machinery and furniture of a ſhip, as experience and ſkill to diſpoſe thoſe machines ſo judiciouſly, that by a mutual aſſiſtance of each other, they may begin and continue the motion of this complicated frame, according to the different deſigns which may be required, or the various exigencies to which it may be reduced. It likewiſe includes the art of renewing or keeping in repair the inſtruments and engines employed in all the purpoſes of navigation.

That part of navigation which regards the piloting or guiding a ſhip along the coaſt, can only be acquired by experience, as it chiefly comprehends a knowledge of the reigning winds, the ſetting of the tides, the different depths of water, and the various ſorts of ground diſcovered in different depths, as ſhells of many colours, ſand great and ſmall, clay, ooze, ſhingle, gravel, ſtones, &c. &c. by which the place of the ſhip may be known many times in the darkeſt night, and conſequently her diſtance from ſome known place on the coaſt. The bearings of the neareſt cape, head-land, promontory, or iſland, is always ſet by the compaſs, and the diſtance allowed by computation, which experience and attention often make the ſeamen very perfect in. See the article COASTING.

That part of navigation by which we underſtand the direction of a ſhip's courſe at ſea, and out of ſight of land, is formed on the principles of plain trigonometry; her progreſs is conſequently meaſured by geometrical rules, and determined by the ſides and angles of a right angled plain triangle, in which the hypothenuſe is converted into diſtance, the perpendicular into difference of latitude, the baſe into departure, and the angles into the courſe and its complement. See COURSE, DEPARTURE, DIFFERENCE of LATITUDE, and DISTANCE.

The courſe of the ſhip is known to be determined by the compaſs, and as the mate at the helm directs the ſhip's motion by this inſtrument, it is conſequently the firſt thing given in the triangles. The diſtance is next meaſured by the log-line and a half or quarter minute glaſs. See COMPASS and LOG-LINE.

Thus having the courſe and diſtance given, we diſcover the difference of latitude and departure, by the following analogy.

As radius,
To the diſtance;
So is the ſine of the courſe,
To the departure.

As radius,
To the diſtance;
So is the co-ſine of the courſe,
To the difference of latitude.

Thus having found the miles of departure, which muſt neceſſarily mean eaſting or weſting from the laſt meridian, we convert it into miles of longitude by Mercator, and reduce the northing or ſouthing alſo into miles of difference of latitude; which operation being performed at every alteration of the courſe on a change of wind, or other accident, the whole northings, ſouthings, eaſtings, and weſtings, ſailed in 24 hours, are diſpoſed in four columns, and the leſſer numbers ſubſtracted from the greater, leave the number of miles of difference of latitude north or ſouth, and of departure eaſt or weſt. The courſe and diſtance reſulting from theſe traverſes for the 24 hours, is then diſcovered by the following proportion.

As the difference of latitude,
To radius;
So is the departure,
To the tangent of the courſe,

As the ſine of the courſe,
To the departure;
So is radius,
To the diſtance.

But if the artiſt in the run of 24 hours has occaſion to believe from circumſtances, that the angle of the courſe is nearer truth than the ſide of the diſtance, and has proved the accuracy of his difference of latitude by a celeſtial obſervation, he will naturally chooſe to find his diſtance and departure by the courſe and the difference of latitude, and will then ſay,

As the co-ſine of the courſe,
Is to the difference of latitude;

So

So is radius,
To the diſtance.

And,

As radius,
To the diſtance;
So is the ſine of the courſe,
To the departure.

On the contrary, if the navigator has more reaſon to rely on the certainty of the diſtance than of the courſe, and has his difference of latitude confirmed by a ſolar obſervation, he is then furniſhed with two ſides of a right angled plain triangle, to diſcover the angle of the courſe and the third ſide; it will then be:

As the diſtance,
To radius;
So is the difference of latitude,
To the ſine complement of the courſe.

Which ſubſtracted from 90° gives the angle of the courſe: and then,

As radius,
To the diſtance;
So is the ſine of the courſe,
To the departure.

But if a ſhip has ſailed between the meridian and parallel, that is, any where on an angle between the four cardinal points, and is pretty exact in her courſe, as alſo in the miles of eaſting or weſting ſhe has made, called her departure, although the diſtance ſhe has run is not accurately determined, nor is her difference of latitude aſcertained; then will the two latter, *viz.* the diſtance and difference of latitude be diſcovered, by having the courſe and the departure given, as thus:

As the ſine of the courſe,
To the departure;
So is radius,
To the diſtance.

As the tangent of the courſe,
To the departure;
So is radius,
To the difference of latitude.

Laſtly, if a ſhip has ſailed a known diſtance, till the line of her departure is likewiſe aſcertained, and it be required to find the courſe ſhe has ſteered, and the difference of latitude ſhe has made, then muſt the departure and diſtance be given to find the courſe and difference of latitude.

As the diſtance,
To radius;
So is the departure,
To the ſine of the courſe.

As the tangent of the courſe,
To the departure;
So is radius,
To the difference of latitude.

Thus have we gone through the ſix caſes of that part of navigation, which is commonly called plain ſailing, and exactly ſimilar to the method of working Mercator's or Wright's, which ſuppoſes the degrees of latitude to be protracted in the ſame ratio, as the degrees of longitude are diminiſhed in their approaches towards the poles of the earth. See MERIDIONAL and MERCATOR.

This extenſion of the degrees of latitude, and conſequently of the difference of latitude between any two places, is called the meridional difference of latitude, and is found by taking the meridional parts of any two places from a table calculated for all parallels, and ſubtracting the leſſer from the greater number, if they are both ſituated north or ſouth of the equator. If one of them lies north, and the other ſouth, then is their meridional difference of latitude found by adding their meridional parts; and having this meridional difference given, together with their difference of longitude, we diſcover the courſe and diſtance as in plain ſailing.

As the meridional difference of latitude,
To the difference of longitude;
So is radius,
To the tangent of the courſe.

As the co-ſine or ſine-complement of the courſe,
To the real difference of latitude;
So is radius,
To the diſtance.

Caſe II. The courſe and diſtance ſailed being given, to find the difference of latitude and difference of longitude.

Firſt, for finding the difference of latitude by rectangular trigonometry, we have this proportion, *viz.* as radius is to the diſtance, ſo is the co-ſine of the courſe to the proper difference of latitude: and hence, it will be eaſy to find the meridional difference of latitude; and to find the difference of longitude, the proportion is, as the radius to the meridional difference of latitude, ſo is the tangent of the courſe to the minutes of difference of longitude.

Caſe III. Both latitudes, *viz.* that ſailing from and coming to, being given; to find the diſtance ſailed, and the difference of longitude.

Firſt, for the difference of longitude, the proportion will be; as radius is to the enlarged or meridional difference of latitude, ſo is the tangent of the courſe to the minutes of difference of longitude.

Then for the direct diſtance, the proportion is; as radius to the proper difference of latitude, ſo is the ſecant of the courſe to the direct diſtance.

Caſe IV. Both latitudes and diſtance ſailed being given, to find the direct courſe and difference of longitude.

Firſt, for finding the angle of the courſe, the proportion is; as the proper difference of latitude is to radius, ſo is the diſtance ſailed to the ſecant of the courſe: then, for the difference of longitude, it will be; as radius to the meridional difference of latitude, ſo is the tangent of the courſe to the minutes of difference of longitude.

Caſe V. One latitude, courſe, and difference of longitude being given: to find the other latitude, and diſtance ſailed.

Firſt, ſay; as the tangent of the courſe is to radius, ſo is the minutes of difference of longitude to the enlarged difference of latitude; whence the minutes of difference of latitude may be found: then to find the direct diſtance, ſay; as radius is to the proper difference of latitude, ſo is the ſecant of the courſe to the direct diſtance.

Caſe VI. One latitude, courſe, and departure being given; to find the other latitude, diſtance ſailed, and difference of longitude.

Firſt, for the diſtance, the proportion is; as the ſine of the courſe is to the departure, ſo is radius to the direct diſtance: then, for finding the proper difference of latitude, we have this analogy, *viz.* as the tangent of the courſe is to the departure, ſo is radius to the proper difference of latitude: next, to find the difference of longitude, ſay; as radius is to the meridional difference of latitude, ſo is the tangent of the courſe to the minutes of difference of longitude.

Caſe VII. Both latitudes and departure being given, to find the courſe, diſtance, and difference of longitude.

Firſt, for the difference of longitude, the proportion is; as the proper difference of latitude is to the departure, ſo is the enlarged difference of latitude to the minutes of difference of longitude: next, for the courſe, it will be; as the proper difference of latitude is to the departure, ſo is radius to the tangent of the courſe: and laſtly, to find the diſtance, we have this analogy; as the ſine of the courſe is to the departure, ſo is radius to the direct diſtance.

Caſe VIII. One latitude, diſtance ſailed, and departure being given; to find the other latitude, difference of longitude, and courſe.

Firſt,

First, for the courſe, ſay; as the diſtance is to radius, ſo is the departure to the fine of the courſe: next, for the difference of latitude, the proportion will be; as radius to the diſtance, ſo is the co-ſine of the courſe to the difference of latitude; whence the meridional difference of latitude may be found: laſtly, to find the difference of longitude, ſay, as the proper difference of latitude is to the departure, ſo is the enlarged or meridional difference of latitude to the minutes of difference of longitude.

In working the different problems of plain, or Mercator's ſailing, there is one univerſal axiom, to which we may refer for ſtating the proportion according to art.

Axiom. In all caſes of plain ſailing, if either of the legs (the difference of latitude or the departure) be made the radius of a circle, the other leg will be a tangent to its oppoſite angle; and the hypothenuſe, or diſtance, will be a ſecant to that ſame angle: but if the diſtance be made radius of a circle, then will the legs be ſines to their oppoſite angles. A general rule to find a ſide, the proportion muſt begin with an angle; but to find an angle, begin with a ſide.

NAVIS, *Argo navis*, or the ſhip Argo, in aſtronomy. See ARGO.

NAUSEA, in medicine, a reaching, or propenſity and endeavour to vomit, ariſing from a loathing of food, excited by ſome viſcous humour that irritates the ſtomach.

In this diſorder the patient is ſo far from deſiring aliment, that he rather loaths it. It either proceeds from a fault in the ſtomach, or elſe is derived from other diſeaſes, or is a ſymptom thereof, particularly acute inflammations, aſthma, dropſy, hypochondriac paſſion, &c. or when the humours are corrupted, and the ſpirits ſuppreſſed, in malignant diſeaſes. Vomiting in this caſe is proper, or purging when that is forbid. To theſe ſhould be joined ſtrengtheners of the ſtomach, and chiefly ſtomachic balſams, made of oil and nutmegs, and diſtilled oils, and ſtomachic plaſters. Hoffman ſays, that there is nothing better than mint, its ſpirituous water, and diſtilled oil; likewiſe maſtic and its ſpirit, or balſam of Peru diſtilled with ſalt of tartar. In acute fevers, eſpecially the malignant, epidemic, and ſpotted, there is generally a nauſea and reaching to vomit, for which reaſon emetics are good: likewiſe in the dyſentery, eſpecially when it is epidemic in a camp, emetics are not only uſeful but neceſſary, with a ſlender diet.

NAUTICAL PLANISPHERE, a deſcription of the terreſtrial globe upon a plane, for the uſe of mariners, more uſually called chart. See CHART.

NAUTILUS, in natural hiſtory, a ſimple ſhell, having no hinge, formed of one continued piece, rolled as it were into a ſpiral form, and having its cavity divided into a great number of cells by tranſverſe partitions, each of which has a perforation, and is continuous to the others, by means of a ſyphunculus carried the whole length of the ſhell. The animal inhabiting this ſhell is a ſepia.

Of the nautili, ſome are thick and ſtrong; others thin, light, and brittle; ſome are aurated, others are not ſo; and ſome are ſmooth on the external ſurface, and others furrowed.

NAVY, the fleet or ſhipping of a prince or ſtate. See FLEET.

NAZARENES, in church hiſtory, a name originally given to all Chriſtians in general, on account that Jeſus Chriſt was of the city of Nazareth; but afterwards reſtrained to a ſet of heretics, whoſe religion conſiſted of a ſtrange jumble of Judaiſm and Chriſtianity; obſerving at the ſame time the Moſaic law, and the ſeveral rites of the Chriſtian religion.

NAZARITES, among the Jews, perſons who either of themſelves, or by their parents, were dedicated to the obſervation of nazariteſhip. They were of two ſorts; namely, ſuch as were bound to this obſervance for only a ſhort time, as a week or month; or thoſe who were bound to it all their lives. All that we find peculiar to the latter's way of life, is, that they were to abſtain from wine and all intoxicating liquors, and never to ſhave or cut off the hair of their heads. The firſt ſort of Nazarites were moreover to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afreſh. Women as well as men might bind themſelves to this vow.

NEALING, or rather ANNEALING, a term uſed for the preparing of ſeveral matters, by heating or baking them in an oven, or the like.

NEALING *of glaſs*. See GLASS.

NEALING *of ſteel*. See STEEL, TEMPERING, &c.

NEAT, or NET-WEIGHT, the weight of a commodity alone, clear of the caſk, bag, caſe, or even filth. See WEIGHT.

NEBEL, in Jewiſh antiquity, the ſame with the pſaltery. See PSALTERY.

NEBULOUS, CLOUDY, in aſtronomy, a term applied to certain of the fixed ſtars, which ſhew a dim hazy light, being leſs than thoſe of the ſixth magnitude, and therefore ſcarce viſible to the naked eye.

NEBULY, or NEBULE'E, in heraldry, is when a coat is charged with ſeveral little figures in form of words, running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved.

NECESSARY, in a philoſophical ſenſe, that which cannot but be, or cannot be otherwiſe. See the next article.

NECESSITY, whatever is done by a neceſſary cauſe, or a power that is irreſiſtible, in which ſenſe it ſtands oppoſed to freedom. See FREEDOM.

NECK, *collum*, in anatomy, is that ſlender part ſituated between the head and the trunk of the body.

The neck conſiſts of the following parts: 1. the common integuments: 2. ſeven vertebræ: 3. a number of muſcles which ſerve to move the head, the neck, the larynx, the pharynx, and the os hyoides: 4. a number of very large arteries, as the carotids, internal and external, and the vertebral ones: 5. of large veins, as the jugular, internal and external, and the vertebral ones: 6. of large nerves, of the parvagum, the intercoſtals, the recurrent, the diaphragmatics, and the vertebral: 7. a part of the ſpinal marrow: 8. the aſpera arteria, or trachea, particularly the larynx, in which is an eminence called the pomum adami: 9. the pharynx, with a part of the oeſophagus: 10. the thyroide, with ſome other ſmaller glands. See the articles LARYNX, PHARYNX, JUGULAR, &c.

Luxation of the NECK. If life remain after ſuch an accident, the patient is to be immediately laid flat on the ground or floor; then the ſurgeon, laying hold of his head, is to extend it ſtrongly, gently moving it from ſide to ſide, till he finds that the neck is reſtored to its natural poſture. Mr. Petit mentions another method, by means of ſlings; but Heiſter gives the preference to the former method, both as being more ſimple, and becauſe the patient can be relieved much ſooner.

NECROSIS, in medicine, a term ſometimes uſed for a mortification, or ſphacelus. See SPHACELUS.

NECTAR, νεκταρ, among ancient poets, the drink of the fabulous deities of the heathens, in contradiſtinction from their ſolid food, which was called ambroſia. See AMBROSIA.

This word is alſo uſed by ſome of the ancients to expreſs honey.

NECTARINE, a fruit differing nothing from the common peach, of which it is a ſpecies, than in having a ſmoother rind and a firmer pulp.

NEEDLE, *acus*, a very common little inſtrument or utenſil, made of ſteel, pointed at one end, and pierced at the other, uſed in ſewing, embroidery, tapeſtry, &c.

Needles make a very conſiderable article in commerce, though there is ſcarce any commodity cheaper, the conſumption of them being almoſt incredible. The ſizes are from N° 1. the largeſt, to N° 25. the ſmalleſt. In the manufacture of needles, German and Hungarian ſteel are of moſt repute. In the making them, the firſt thing is to paſs the ſteel through a coal-fire, and, under a hammer, to bring it out of its ſquare figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing-iron, and returned into the fire, and drawn through a ſecond hole of the iron, ſmaller than the firſt, and thus ſucceſſively, from hole to hole, till it has acquired the degree of fineneſs required for that ſpecies of needles, obſerving every time it

it is to be drawn that it be greaſed over with lard, to render it more manageable. The ſteel thus reduced to a fine wire, is cut in pieces of the length of the needles intended. Theſe pieces are flattened at one end on the anvil, in order to form the head and eye: they are then put into the fire to ſoften them farther, and thence taken out and pierced at each extreme of the flat part on the anvil, by force of a puncheon of well-tempered ſteel, and laid on a leaden block to bring out, with another puncheon, the little piece of ſteel remaining in the eye. The corners are then filed off the ſquare of the heads, and a little cavity filed on each ſide of the flat of the head: this done the point is formed with a file, and the whole filed over; they are then laid to heat red hot on a long, flat, narrow iron, crooked at one end, in a charcoal fire, and when taken out hence, are thrown into a baſon of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them ſoft; the medium is learned by experience. When they are thus hardened, they are laid in an iron-ſhovel on a fire, more or leſs briſk in proportion to the thickneſs of the needles; taking care to move them from time to time. This ſerves to temper them, and take off their brittleneſs: great care here too muſt be taken of the degree of heat. They are then ſtraightened one after another with the hammer, the coldneſs of the water uſed in hardening them having twiſted the greateſt part of them. The next proceſs is the poliſhing them. To do this they take twelve or fifteen thouſand needles, and range them in little heaps againſt each other, on a piece of new buckram, ſprinkled with emery-duſt. The needles thus diſpoſed, emery-duſt is thrown over them, which is again ſprinkled with oil of olives; at laſt the whole is made up into a roll, well bound at both ends. This roll is then laid on a poliſhing-table, and over it a thick plank loaden with ſtones, which two men work backwards and forwards a day and a half, or two days, ſucceſſively; by which means the roll thus continually agitated by the weight and motion of the plank over it, the needles withinſide being rubbed againſt each other with oil and emery, are inſenſibly poliſhed. After poliſhing they are taken out, and the filth waſhed off them with hot-water and ſoap: they are then wiped in hot bran, a little moiſtened, placed with the needles in a round box, ſuſpended in the air by a cord, which is kept ſtirring till the bran and needles be dry. The needles thus wiped in two or three different brans, are taken out and put in wooden veſſels, to have the good ſeparated from thoſe whoſe points or eyes have been broken either in poliſhing or wiping: the points are then all turned the ſame way, and ſmoothed with an emery-ſtone turned with a wheel. This operation finiſhes them, and there remains nothing but to make them into packets of 250 each.

Magnetical NEEDLE, in navigation, a needle touched with a loadſtone, and ſuſtained on a pivot or center, on which playing at liberty, it directs itſelf to certain points in or under the horizon; whence the magnetical needle is of two kinds, viz. horizontal and inclinatory. See MAGNET.

NEGATION, in logic, an act of the mind, affirming one thing to be different from another; as, that the ſoul is not matter.

NEGATIVE, in general, ſomething that implies a negation: thus we ſay, negative quantities, negative ſigns, negative powers, &c. See QUANTITY, SIGN, POWER, &c.

Our words and ideas, ſays Dr. Watts, are ſo unhappily linked together, that we can never know which are poſitive, which negative ideas, by the words that expreſs them; for ſome poſitive terms denote a negative idea, as dead: and there are both poſitive and negative terms invented to ſignify the ſame and contrary ideas, as unhappy and miſerable.

To this may alſo be added, that ſome words, which are negative in the original language, ſeem poſitive in Engliſh, as *abyſs*. The way therefore to know whether any idea be negative or not, is to conſider whether it primarily implies the abſence of any poſitive being, or mode of being; if ſo, then it is a negative idea, otherwiſe a poſitive one.

According to logicians, the only way to prove a negative, is by converting it into an affirmative.

NEGATIVE *Pregnant*, a negative that implies or brings forth an affirmative; as where a perſon is impleaded to have done a certain thing on ſuch a day, &c. and denies the thing generally, without alleging any thing farther, it is a negative pregnant plea, becauſe ſuch pleading may nevertheleſs imply that he did it in ſome ſort.

NEGROES, properly the inhabitants of Nigritia, in Africa; alſo called blacks and moors; but this name is now given to all the blacks.

The origin of the negroes, and the cauſe of this remarkable difference from the reſt of the human ſpecies, has much perplexed the naturaliſts: Mr. Boyle has obſerved, that it cannot be produced by the heat of the climate; for though the heat of the ſun may darken the colour of the ſkin, yet experience does not ſhew that it is ſufficient to produce a true blackneſs, like that of the negroes.

In Africa itſelf, many nations of Æthiopia are not black, nor were there any blacks originally in the Weſt-Indies. In many parts of Aſia, under the ſame parallel with the African region, inhabited by blacks, the people are but tawney. He adds, that there are negroes in Africa beyond the ſouthern tropic, and that a river ſometimes parts nations, one of which is black, and the other only tawny. Dr. Barriere alledges, that the gall of negroes is black, and being mixed with their blood, is depoſited between their ſkin and ſcarf-ſkin. However, Dr. Mitchell, of Virginia, in the Philoſophical Tranſactions, N° 476, has endeavoured by many learned arguments to prove, that the influence of the ſun in hot countries, and the manner of life of their inhabitants, are the remote cauſes of the colour of negroes, Indians, &c. and indeed it would be a ſtrong confirmation of his doctrine, if we could ſee any people, originally white, become black and woolly by tranſplantation, or *vice verſa*.

NEHEMIAH, a canonical book of the Old Teſtament, ſo called from the name of its author. Nehemiah was born at Babylon, during the captivity, and ſucceeded Ezra in the government of Judah and Jeruſalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus, king of Perſia; when the opportunities he had of being daily in the king's preſence, together with the favour of Eſther the queen, procured him the favour of being authorized to repair and fortify the city of Jeruſalem, in the ſame manner as it was before its deſtruction by the Babylonians. On his going to Jeruſalem, he finiſhed the rebuilding of the walls in fifty-two days, and dedicated the gates of the city with great ſolemnity. He then reformed ſome abuſes which had crept in among his countrymen, particularly the extortion of the uſurers, by which the poor were ſo oppreſſed as to be forced to ſell their lands and children for ſupport. After which he returned to Perſia, and came back again with a new commiſſion, by virtue of which he regulated every thing relating both to the ſtate and religion of the Jews. The hiſtory of theſe tranſactions is the ſubject of this book.

NEIF, *nativa*, in law-books, denotes a ſhe villain. See VILLAIN.

NEMÆAN *Games* were ſo called from Nemæa, a village between the cities of Cleone and Phlius, where they were celebrated every third year. The exerciſes were chariot-races, and all the parts of the pentathlum. Theſe games were inſtituted in memory of Opheltes, or Archemorus, the ſon of Euphetes and Creuſa, and nurſed by Hypſipyle; who leaving him in a meadow, while ſhe went to ſhew the beſiegers of Thebes a fountain, at her return found him dead, and a ſerpent twined about his neck: whence the fountain, before called Langia, was named Archemorus; and the captains, to comfort Hypſipyle, inſtituted theſe games. Others aſcribe their inſtitution to Hercules, after his victory over the Nemæan lion.

NEMINE CONTRADICENTE, *none contradicting it*, a term chiefly uſed in parliament when any thing is carried without oppoſition.

NENIA, or NÆNIA, in ancient poetry, a mournful

kind of ſong, filled with the praiſes of ſome deceaſed perſon, and ſung during the celebration of the funeral.

NEOMENIA, or NOUMENIA, a feſtival of the ancient Greeks, at the beginning of every lunar month, which was, as the name imports, obſerved upon the day of the new moon, in honour of all the gods, but eſpecially Apollo, who was called Neomenios.

The Jews had alſo their Neomenia, or feaſt of the new moon, on which peculiar ſacrifices were appointed, and on this day they had a ſort of family entertainment and rejoicing. The moſt celebrated Neomenia of all others, was that at the beginning of the civil year, or firſt day of the month Tiſri, on which no ſervile labour was performed: they then offered particular burnt-ſacrifices, and ſounded the trumpets of the temple. The modern Jews keep the Neomenia only as a feaſt of devotion, which any one may obſerve or not, as he pleaſes.

NEOPHYTES, new plants, a name given by the ancient Chriſtians, to thoſe heathens who had newly embraced the faith; ſuch perſons being conſidered as regenerated, or born anew by baptiſm. The term neophytes has been alſo uſed for new prieſts, or thoſe juſt admitted into orders, and ſometimes for the novices in monaſteries. It is ſtill applied to the converts made by the miſſionaries among the infidels.

NEOTTIA, bird's-neſt, in botany, a genus of plants, the flower of which conſiſts of five ovato-oblong petals, connivent at the points: the nectarium is undivided, equal in length to the petals, and furniſhed with a denticulation to each ſide: the fruit is a rugoſe, oblong, capſule, containing a great number of ſeeds.

NEPENTHES, νηπενθης, a medicine, mentioned by Homer, as moſt efficacious againſt grief and ſorrow. He ſays, that whoever ſhould take it mixed with wine, could not be ſenſible of grief for that whole day, though his father or mother were to die.

NEPER's RODS, or BONES, an inſtrument invented by J. Neper, baron of Merchiſton, in Scotland, whereby the multiplication and diviſion of large numbers are much facilitated.

As to the conſtruction of NEPER's ROD: ſuppoſe the common table of multiplication to be made upon a plate of metal, ivory, or paſte-board, and then conceive the ſeveral columns (ſtanding downwards from the digits on the head) to be cut aſunder; and theſe are what we call Neper's rods for multiplication. But then there muſt be a good number of each; for as many times as any figure is in the multiplicand, ſo many rods of that ſpecies (*i. e.* with that figure on the top of it) muſt we have; though ſix rods of each ſpecies will be ſufficient for any example in common affairs: there muſt be alſo as many rods of 0's.

But before we explain the way of uſing theſe rods, there is another thing to be known, viz. that the figures on every rod are written in an order different from that in the table. Thus, the little ſquare ſpace or diviſion in which the ſeveral products of every column are written, is divided into two parts by a line acroſs from the upper angle on the right to the lower on the left; and if the product is a digit, it is ſet in the lower diviſion; if it has two places, the firſt is ſet in the lower, and the ſecond in the upper diviſion; but the ſpaces on the top are not divided. Alſo there is a rod of digits, not divided, which is called the index rod, and of this we need but one ſingle rod.

Multiplication by NEPER's RODS: firſt lay down the index-rod; then on the right of it ſet a rod, whoſe top is the figure in the higheſt place of the multiplicand: next to this again, ſet the rod whoſe top is the next figure of the multiplicand; and ſo on in order, to the firſt figure. Then is your multiplicand tabulated for all the nine digits; for the ſame line of ſquares ſtanding againſt every figure of the index rod, you have the product of that figure, and therefore you have no more to do but to tranſfer the products and ſum them. But in taking out theſe products from the rods, the order in which the figures ſtand, obliges you to a very eaſy and ſmall addition: thus, begin to take out the figure in the lower part, or unit's place, of the ſquare of the firſt rod on the right; add the figure in the upper part of this rod to that in the lower part of the next, and ſo on, which may be done as faſt as you can look on them.

Diviſion of NEPER's RODS: firſt tabulate your diviſor; then you have it multiplied by all the digits, out of which you may chooſe ſuch convenient diviſors as will be next leſs to the figures in the dividend, and write the index anſwering in the quotient, and ſo continually till the work is done.

NEPHEW, a term relative to uncle and aunt, ſignifying a brother or ſiſter's ſon, who, according to the civil law, is in the third degree of conſanguinity; but according to the canon in the ſecond.

NEPHRITIC, ſomething that relates to the kidneys. See KIDNEY.

NEPHRITIC WOOD, *Lignum Nephriticum*, an American wood, brought to us in large compact ponderous pieces, without knots; the outer part is of a whitiſh, or pale yellowiſh colour; the medullary ſubſtance of a dark browniſh or reddiſh. This wood, macerated in water for half an hour or an hour, imparts a deep tincture, appearing, when placed betwixt the eye and the light, of a golden colour; in other ſituations of a fine blue: a property in which it agrees with the bark of the aſh tree, and differs from all other known woods. Pieces of a different kind of wood are often mixed with it, which give only a yellow tincture to water.

This wood ſtands greatly recommended in difficulties of urine, nephritic complaints, and all diſorders of the kidneys and urinary paſſages; and is ſaid to have this peculiar advantage, that it does not, like the warmer diuretics, heat or offend the parts. The blue aqueous tincture is directed to be uſed as common drink, and freſh water to be poured on the remaining wood ſo long as it communicates any blueneſs. For medicinal purpoſes Geoffroy ſays, he has ſeen ſome inſtances of its being uſed, but without ſucceſs; and indeed, whatever may be the virtues of ſtrong infuſions or extracts of the wood, the exceedingly dilute blue tincture cannot be expected to have much efficacy.

NEPHRITICS, in pharmacy, medicines proper for diſeaſes of the kidneys, eſpecially the ſtone. See the article STONE.

NEPHRITIS, *Dolor Nephriticus*, or NEPHRITIC CHOLIC, in medicine, a painful diſeaſe, occaſioned by the ſtone or gravel in the kidneys, in which there is an inflammation.

The word is Greek, and derived from νεφρος, a kidney.

That the kidneys labour under a true inflamnation, may be known from the burning pungent pain of the part where the kidneys lie; from an acute continual fever; from the ſmall quantity of urine, which is deep-coloured, or, in the height of the diſorder, aqueous; the ſtupor of the adjacent leg; the pain of the groin, and contiguous teſticle; pain of the ilium; the vomiting of bile, and continual eructations.

Such an inflammation is cured, when nature is benign, and the diſeaſe favourable, firſt, by reſolution; ſecondly, by a copious, red, and thick urine, continually diſcharged before the ſeventh, or at moſt the fourteenth day of the diſeaſe; and thirdly, by a copious diſcharge from the hæmorrhoidal veins in the beginning of the diſorder.

The diſorder, when the inflammation is known to be preſent, is to be cured firſt by the general remedies appropriated to the cure of all inflammations, as veneſection, revulſion, and dilution; ſecondly, by mild, emollient, and antiphlogiſtic decoctions, drank in large quantities.

Thirdly, this ſpecies of the diſorder is cured by clyſters, fomentations, and baths; and fourthly, by mild and moiſt aliments, by reſt, by not lying too warm in bed, and eſpecially not lying on the back.

If the pains and convulſions are exceſſively violent, opiates are beneficial. The exceſſive vomiting is to be relieved by a frequent exhibition of tepid water, edulcorated with honey. Thus a nephritis ariſing from a ſtone impacted in the ureters and kidneys, may be ſafely cured.

If the diſorder be protracted, notwithſtanding the above method of cure, beyond the ſeventh day, an abſceſs is to be dreaded, the formation of which may be known from a remiſſion of the pain, ſucceeded by a pulſation,

and frequently returning horror, a weight and ſtupor of the part, from fœtid, apparently ſaline, and putrified urine. We are firſt to uſe powerfully maturating and emollient medicines; then, when the urine appears purulent, we muſt exhibit diuretics, conſiſting of pure medicated waters, whey, &c. uſing at the ſame time balſamics.

If this ſuppuration ſhould continue long, the whole kidney, being conſumed, forms a kind of uſeleſs bag; and in this caſe, a tabes renalis is frequently preſent.

If a ſchirrhus be formed, there ariſes an incurable palſy, or lameneſs of the ſubjacent leg. Hence alſo are often produced a ſlow conſumption and dropſy.

If a ſmall quantity of the inflammatory matter remain in the minute follicle of the urine, it forms a kind of baſis, to which the ſabulous matter of the urine gradually adhering, forms a ſtone in the kidneys, which is by degrees augmented.

A nephritis alſo ſometimes degenerates into a gangrene. *Boerhaave's Aphor.*

NEREIDS, in the Pagan theology, ſea nymphs, daughters of Nereus and Doris. Heſiod reckons up fifty of them; and Homer gives us a liſt and deſcription of thirty-nine nereids. Virgil's liſt of the nereids is ſhorter, but diverſified with pretty circumſtances, as may be ſeen *Georg.* lib. iv. v. 336, *& ſeq.*

The nereids were eſteemed very handſome, inſomuch that Caſſiope, the wife of Cepheus, king of Ethiopia, having triumphed over all the beauties of her age, and daring to vie with the nereids, they were ſo enraged, that they ſent a prodigious ſea-monſter into the country; and to appeaſe them, ſhe was commanded by the oracle to expoſe her daughter Andromeda, bound to a rock, to be devoured by the monſter.

In ancient monuments the nereids are repreſented riding upon ſea-horſes, ſometimes with an entire human form, and, at other times, with the tail of a fiſh.

NERVES, *nervi*, in anatomy, are cylindrical whitiſh parts, uſually fibroſe in their ſtructure, or compoſed of cluſters of filaments, ariſing from the brain, or rather from its medulla oblongata within the ſkull, and from the ſpinal marrow, and running from thence to every part of the body.

Structure and Uſe of the NERVES. This is eaſily perceived in moſt of the larger, and ſome of the ſmaller ones; for beſides the blood-veſſels they receive, and the membranes they are ſurrounded with, they are ſeen to be compoſed of a fibrous matter, or, as it were, of bundles or cluſters of white, cylindrical, and very ſlender filaments; which, on the ſtricteſt examination, appear to be ſolid, and without any cavity. Liewenhoeck indeed affirms, that he had often found a cavity in them; but he is not free from errors in many of his microſcopical obſervations. But though we cannot diſcover any cavity, much leſs a fluid contained in them; yet it is very poſſible that there may be ſuch cavities, and ſuch a fluid, only too ſmall to be perceived by us: and for the actual exiſtence of ſuch a fluid, known by the name of animal ſpirits, many probable arguments are adduced.

The great uſe of the nerves, therefore, though we are not able perfectly to demonſtrate it, ſeems to be to convey to all parts of the body a fluid of an extremely ſubtile kind, ſecreted in the brain and ſpinal marrow, and deſtined for no leſs noble a purpoſe than the ſenſation, motion, and nutrition of the ſeveral parts of the whole human fabric. Thoſe who would enter farther into this ſubject, may conſult Heiſter's Anatomy; Boerhaave's Chapter on the Brain, in his Inſtitutes; Morgagni's Adverſar. where he treats it judiciouſly and deeply; and after theſe, Burggrave on the Exiſtence of the Animal Spirits. See alſo the article BRAIN.

Origin, Diſtribution, and Names of the NERVES. The nerves are uſually divided into two kinds, thoſe which ariſe from the brain, and thoſe ariſing from the ſpinal marrow.

The nerves of the brain are nine pair. 1. The olfactory pair, which paſſing through the os cribroſum, are ſpread over the membrane of the noſtrils. 2. The optic pair, which by their expanſion form the retina of the eye. 3. The motory pair of the eyes, each of which is divided near the orbit, into ſix parts, or branches; of which, in human ſubjects, the firſt branch goes to the elevator palpebræ; the ſecond, to the elevator of the eye; the third, to the depreſſor; the fourth, to the adducent; the fifth, to the inferior oblique muſcle; and the ſixth, into the tunics of the eye: but, in other animals, they are divided much otherwiſe. 4. The pathetic pair of Willis, which are very ſmall, and run to the trochlear muſcle of the eye. 5. The guſtatory pair, which are very large, and divided within the cranium into three branches immediately under the dura mater: of theſe the firſt branch, called the ophthalmic, runs to various parts of and about the eye, the eye-lids, the muſcles of the forehead and noſe, and the integuments of the face. The ſecond branch may be called the ſuperior maxillary one, as being finally diſtributed through all parts of the upper jaw, the lips, noſe, palate, uvula, gums, teeth; a branch of it alſo runs to the ear, and joining with a branch of the ſeventh pair, forms the chorda tympani. The third branch may be called the maxillaris inferior, as being diſtributed over the ſeveral parts of the lower jaw, the tongue, and other parts of the mouth; whence the whole pair of nerves has obtained the name of par guſtatorium; though a great part of them ſerves to very different purpoſes, and is carried to parts that have nothing to do with taſting. 6. The abducent pair, except a branch from the formation of the intercoſtal nerve, is wholly carried to the abducent muſcle of the eye; whence its name. The intercoſtal nerve is formed either of ramifications of the two preceding nerves, or only of thoſe of the ſixth pair. It makes its way out of the cranium by the paſſage of the internal carotid, and deſcends near the eighth pair through the neck; and thence through the breaſt and abdomen, even to the pelvis; and, in its way, makes various plexuſes and ganglia, and ſends branches to almoſt all the parts contained in the breaſt and abdomen. 7. The auditory pair ariſe with two trunks; the one of which is called the portio dura, or hard portion; the other the portio mollis, or ſoft portion. This laſt enters the foramen of the os petroſum, and thence through various little apertures gets into the labyrinth of the ear, where it is expanded over all its parts, and conſtitutes the primary organ of hearing. The harder portion, paſſing the aquæduct of Fallopius, ſends back one branch into the cavity of the cranium: it alſo ſends off another branch which helps to form the chorda tympani; and others to the muſcles of the tympanum. The reſt of this pair goes to the external ear, the pericranium, the muſcles of the os hyoides, the lips, the eye-lids, and the parotids. 8. The par vagum, with the acceſſorius of Willis, paſs out near the laternal ſinuſes of the dura mater, and deſcending through the neck and thorax to the abdomen, ſend out branches by the way to the larynx, the pharynx, the heart, the lungs, and eſpecially to the ſtomach. It alſo ſends off from the upper part of the thorax, large branches, which are variouſly implicated in the neck, thorax, and abdomen, with the linguals, the cervicals, and the intercoſtals. 9. The lingual pair go immediately to the tongue, and are called by ſome the motory nerves of the tongue; but by others, with more juſtice, the guſtatory nerves.

We are to obſerve, ſays Heiſter, that the pair of nerves, which the generality of writers have called the tenth pair of the head, are, for many unanſwerable reaſons, to be properly called the firſt pair of nerves of the neck.

Of the nerves which ariſe from the ſpinal marrow, there are properly thirty-two pair.

Thoſe of the neck are no leſs than eight pair; and from them there are innumerable branches diſtributed through the muſcles of the head, the neck, the ſcapula, and the humerus: from the third, fourth, and fifth pair are formed the nerves of the diaphragm; and the ſixth, ſeventh, and eighth pair, together with the firſt pair of the back, form the ſix robuſt nerves of the arm and hands. To this diviſion is the acceſſory ſpinal nerve of Willis to be referred, which ariſes about the origin of the third or fourth pair.

The nerves of the back are twelve pair, which, beſides the branch they give to the brachial nerves, run entirely in the ſame furrow along the courſe of the ribs, and are diſperſed over the pleura, the intercoſtal, pectoral,

toral, and abdominal muſcles, the breaſt, and other parts of the thorax.

The nerves of the loins are five pair. Theſe are in general diſperſed over the loins, the peritonæum, and the integuments and muſcles of the abdomen: and beſides this, their firſt pair often gives, on each ſide, a branch to the diaphragm. The ſecond pair after inoſculating with the branches of the firſt, third, and fourth pair, forms the crural nerves, which are diſtributed over the anterior part of the thigh: and in the ſame manner a branch is formed of the conjunctions of the ſecond, third, and fourth pair, which paſſes through the great foramen of the os pubis to the ſcrotum, the teſticles, and the adjoining parts. The fourth and fifth pair of the nerves of the loins, joining with the firſt, ſecond, third, and fourth pair of the os ſacrum, compoſe the nerve called iſchiatic, which is the largeſt in the body; it deſcends along the hinder part of the thigh, and its branches are diſtributed over the whole leg, the foot, and toes.

The nerves of the os ſacrum form five or ſix pair, though not always determinately and regularly ſo: they paſs through the foramina of this bone, and the ſuperior ones of them, as already obſerved, compoſe the iſchiatic nerve; and what remains is diſperſed, in a multitude of ramifications, over the parts contained in the pelvis, the inteſtinum rectum, the bladder, the parts of generation, and the parts adjacent.

NEST, *Nidus*. See NIDUS.

NESTORIANS, a Chriſtian ſect, the followers of Neſtorius, biſhop and patriarch of Conſtantinople; who, about the year 429, taught that there were two perſons in Jeſus Chriſt, the divine and the human, which are united, not hypoſtatically or ſubſtantially, but in a myſtical manner: whence he concluded, that Mary was the mother of Chriſt, and not the mother of God. For this opinion, Neſtorius was condemned and depoſed by the council of Epheſus; and the decree of this council was confirmed by the emperor Theodoſius, who baniſhed the biſhop to a monaſtery.

Thoſe Chriſtians who at this day are called Neſtorians and Chaldeans, are very numerous, and are ſpread over Meſopotamia, and along the river Tigris and Euphrates: they are even got into the Indies, and into Tartary and China. Thoſe of India ſettled there under a Neſtorian prieſt called John, who, in the year 1145, got himſelf declared king of Indoſtan, and grew very famous under the name of Preſter John. The Neſtorians, though they ſpeak the language of the reſpective countries, only officiate in the Chaldee or Syriac tongue. The Neſtorian monks are habited in a black gown tied with a leathern girdle, and wear a blue turban. The nuns are dreſſed much after the ſame manner, excepting that they tie a kind of black veil about their heads, and about their chins. They muſt be forty years old before they take the monaſtic habit.

NETHERLANDS, anciently called Belgia, but ſince denominated Low-Countries, or Netherlands, from their low ſituation, are ſituated between 2 and 7° of eaſt longitude, and between 50 and 53° 30′ of north latit. and are bounded by the German ſea on the north; Germany on the eaſt; by Lorrain and France on the ſouth; and by another part of France and the Britiſh ſeas on the weſt; extending near three hundred miles in length from north to ſouth, and two hundred miles in breadth from eaſt to weſt. They conſiſt of ſeventeen provinces, ten of which are called the Auſtrian and French Netherlands, and the other the Seven United Provinces.

NETTLE, *Urtica*, in botany, a genus of plants, without any flower petals: the ſeed is ſingle, and contained in the cup, which cloſes for that purpoſe.

The root of the common-nettle is accounted diuretic and lithontriptic: it ſerves alſo to purify the blood, and is good in ſpittings of blood, hæmorrhages, and the menſes. The ſeeds of the Roman-nettle are recommended in the aſthma, and other diſorders of the lungs.

NEURITICS, *Nervines*, *Neuritica*, *Nervina*, in phyſic, are ſuch medicines as are proper for diſeaſes of the nerves and nervous parts, as the membranes, ligaments, &c.

The word is Greek, and formed from νευρον, a nerve.

NEUROGRAPHY, *Neurographia*, a deſcription of the nerves, with figures thereof engraved.

The word is Greek, and formed of νευρον, a nerve, and γραφω, to deſcribe.

NEUTER, or NEUTER-GENDER, in grammar, a ſort of gender of nouns in the learned languages, which are neither maſculine nor feminine. See the article GENDER.

NEUTRAL SALTS, in chemiſtry, are a ſort of intermediate ſalts between acids and alcalies, participating of the nature of both, ſo that one does not predominate over the other.

Perfectly neutral ſalts are ſuch as produce no degree of effervеſcence, but become quite ſaturated upon the affuſion of any acid or alcaline liquor. The chief of this kind among the native ſalts are common ſalt, nitre, aphronitrum, the eſſential ſalts of plants, and thoſe obtained by boiling from ſome medicinal and acidulated ſprings. Thoſe prepared by art, are the arcanum duplicatum, antimoniated nitre, Glauber's ſalts, and vitriolated tartar.

Salts of a temperate and neutral nature, are not only of all others the moſt ſalutary, but alſo the ſafeſt and moſt efficacious, both for preventing and curing ſome of the diſorders incident to the human body.

NEUTRALITY, the ſtate of a perſon or thing that is neuter.

NEW-MOON, *Neomenia*, that ſtate of the moon a little before and a little after her conjunction with the ſun. See MOON and NEOMENIA.

NEWEL, in architecture, is the upright poſt which a pair of winding-ſtairs turn about: this is properly a cylinder of ſtone, which bears on the ground, and is formed by the end of the ſteps of the winding-ſtairs. There are alſo newels of wood, which are pieces of timber placed perpendicularly, receiving the tenons of the ſteps of the wooden-ſtairs into their mortiſes, and on which are fitted the ſhafts and reſts of the ſtair-caſe, and the flights of each ſtory.

NEWT, or EFT, in zoology. See the articles EFT and LIZARD.

NEWTONIAN PHILOSOPHY, the doctrine of the univerſe, and particularly of the heavenly bodies; their laws, affections, &c. as delivered by Sir Iſaac Newton.

The term Newtonian philoſophy is applied very differently by different authors. Some, under this philoſophy, include all the corpuſcular philoſophy, conſidered as it now ſtands corrected and reformed by the diſcoveries and improvements made in the ſeveral parts thereof by Sir Iſaac Newton. In this ſenſe it is that 'sGraveſande calls his Elements of Phyſics, an Introduction to the Newtonian Philoſophy; and in this ſenſe the Newtonian is the ſame with the new philoſophy, in oppoſition to the Carteſian, the Peripatetic, and the ancient corpuſcular philoſophy. See CARTESIAN, &c.

Others, by Newtonian philoſophy, mean the method or order which Sir Iſaac obſerves in philoſophizing, viz. the reaſoning and drawing of concluſions directly from phænomena, excluſive of all previous hypotheſes; the beginning from ſimple principles, deducing the firſt powers and laws of nature from a few ſelect phænomena, and then applying thoſe laws, &c. to account for other things: and in this ſenſe, the Newtonian is the ſame with the experimental philoſophy. See the article EXPERIMENTAL.

Others again, by Newtonian philoſophy, mean that wherein phyſical bodies are conſidered mathematically, and where geometry and mechanics are applied to the ſolution of phænomena; in which ſenſe, the Newtonian is the ſame with the mechanical and mathematical philoſophy. See MECHANICAL.

Others again, by Newtonian philoſophy, underſtand that part of the phyſical knowledge which Sir Iſaac Newton has handled, improved, and demonſtrated in his Principia.

And laſtly, others, by Newtonian philoſophy, mean the new principles which Sir Iſaac has brought into philoſophy, the new ſyſtem founded thereon, and the new ſolutions of phænomena thence deduced; or that which characterizes and diſtinguiſhes his philoſophy from all others:

others: and this is the ſenſe in which we ſhall chiefly conſider it.

As to the hiſtory of this philoſophy, we have but little to ſay: it was firſt made public in 1686, by the author, then a fellow of Trinity College, Cambridge; and in the year 1713, republiſhed with conſiderable improvements. Several other authors have ſince attempted to make it plainer, by ſetting aſide many of the more ſublime mathematical reſearches, and ſubſtituting either more obvious reaſonings or experiments in lieu thereof; particularly Mr. Whiſton, in his Prelect. Phyſ. Mathem. 's Graveſande, in his Elem. and Inſt. and lately, by the learned Comment of Le Seur and Jacquier upon Sir Iſaac's Principia.

The philoſophy itſelf is laid down chiefly in the third book of the Principia; the two preceding books being taken up in preparing the way, and laying down ſuch principles of mathematics as have the moſt relation to philoſophy: ſuch are the laws and conditions of powers; and theſe, to render them leſs dry and geometrical, the author illuſtrates by ſcholia in philoſophy, relating chiefly to the denſity and reſiſtance of bodies, the motion of light and ſounds, a vacuum, &c.

In the third book he proceeds to the philoſophy itſelf; and from the ſame principles deduces the ſtructure of the univerſe, and the powers of gravity, whereby bodies tend towards the ſun and planets; and from theſe powers, the motions of the planets and comets, the theory of the moon and the tides. This book, which he calls De Mundi Syſtemate, he tells us, was firſt wrote in the popular way; but conſidering, that ſuch as are unacquainted with the ſaid principles, would not conceive the force of the conſequences, nor be induced to lay aſide their ancient prejudices; for this reaſon, and to prevent the thing from being in continual diſpute, he digeſted the ſum of that book into propoſitions, in the mathematical manner, ſo as it might only come to be read by ſuch as had firſt conſidered the principles; not that it is neceſſary a man ſhould maſter them all, many of them, even the firſt rate mathematicians, would find a difficulty in getting over. It is enough to have read the definitions, laws of motion, and the three firſt ſections of the firſt book; after which, the author himſelf directs us to paſs on to the book De Syſtemate Mundi.

The great principle on which the whole philoſophy is founded, is the power of gravity: this principle is not new; Kepler, long ago, hinted it in his Introduct. ad Mot. Martis. He even diſcovered ſome of the properties thereof, and their effects in the motions of the primary planets; but the glory of bringing it to a phyſical demonſtration, was reſerved to the Engliſh philoſopher. See GRAVITATION.

His proof of this principle from phænomena, together with the application of the ſame principle to the various other appearances of nature, or the deducing thoſe appearances from that principle, conſtitute the Newtonian ſyſtem; which, drawn in miniature, will ſtand thus:

1. The phænomena are, 1. That the ſatellites of Jupiter do, by radii drawn to the center of the planet, deſcribe areas proportional to their times; and that their periodical times are in a ſeſquiplicate ratio of their diſtances from its center; in which the obſervations of all aſtronomers agree. 2. The ſame phænomenon holds of the ſatellites of Saturn, with regard to Saturn; and of the moon, with regard to the earth. 3. The periodical times of the primary planets about the ſun, are in a ſeſquiplicate ratio of their mean diſtances from the ſun. But, 4. The primary planets do not deſcribe areas any way proportional to their periodical times about the earth; as being ſometimes ſeen ſtationary, and ſometimes retrograde, with regard thereto. See SATELLITE, PERIOD, &c.

2. The powers whereby the ſatellites of Jupiter are conſtantly drawn out of their rectilinear courſe, and retained in their orbits, reſpect the center of Jupiter, and are reciprocally as the ſquares of their diſtances from the ſame center. The ſame holds of the ſatellites of Saturn, with regard to Saturn; of the moon, with regard to the earth; and of the primary planets, with regard to the ſun. See CENTRAL FORCES.

3. The moon gravitates towards the earth, and by the power of that gravity is retained in her orbit: and the ſame holds of the other ſatellites with reſpect to their primary planets; and of the primaries with reſpect to the ſun.

As to the moon, the propoſition is thus proved: the moon's mean diſtance is ſixty ſemidiameters of the earth; her period, with regard to the fixed ſtars, is twenty-ſeven days, ſeven hours, forty-three minutes; and the earth's circumference 123249600 Paris feet. Now, ſuppoſing the moon to have loſt all her motion, and to be let drop to the earth, with the power which retains her in her orbit, in the ſpace of one minute ſhe will fall $15\frac{1}{12}$ Paris feet; the arch ſhe deſcribes in her mean motion, at the diſtance of 60 diameters of the earth, being the verſed ſign of $15\frac{1}{12}$ Paris feet. Hence, as the power, as it approaches the earth, increaſes in a duplicate ratio of the diſtance inverſely, ſo as at the ſurface of the earth it is 60×60 greater than at the moon; a body, falling with that force in our region, muſt, in a minute's time, deſcribe the ſpace of 60×60 $15\frac{1}{12}$ Paris feet, and $15\frac{1}{12}$ Paris feet in the ſpace of one ſecond.

But this is the rate at which bodies fall by their gravity at the ſurface of our earth; as Huygens has demonſtrated by experiments with pendulums. Conſequently, the power whereby the moon is retained in her orbit, is the very ſame we call gravity; for, if they were different, a body, falling with both powers together, would deſcend with double the velocity, and in a ſecond of time deſcribe $30\frac{1}{6}$ feet. See the articles DESCENT and MOON.

As to the other ſecondary planets, their phænomena, with reſpect to their primary ones, being of the ſame kind with thoſe of the moon about the earth, it is argued by analogy, they depend on the ſame cauſes; it being a rule or axiom all philoſophers agree to, that effects of the ſame kind have the ſame cauſes. Again, attraction is always mutual, that is, the re-action is equal to the action; conſequently the primary planets gravitate towards their ſecondary ones, the earth towards the moon, and the ſun towards them all. And this gravity, with regard to each ſeveral planet, is reciprocally as the ſquare of its diſtance from the center of gravity. See ATTRACTION, &c.

4. All bodies gravitate towards all the planets, and their weight towards any one planet, at equal diſtances from the center of the planet, is proportional to the quantity of matter in each. See WEIGHT.

For the law of the deſcent of heavy bodies towards the earth, ſetting aſide their unequal retardation from the reſiſtance of the air, is this, that all bodies fall equal ſpaces in equal times; but the nature of gravity or weight, no doubt, is the ſame on the other planets as on the earth.

Suppoſe, e. gr. ſuch bodies raiſed to the ſurface of the moon, and together with the moon deprived at once of all progreſſive motion, and dropped towards the earth: it is ſhewn, that in equal times they will deſcribe equal ſpaces with the moon; and therefore, that their quantity of matter is to that of the moon, as their weight to its weight.

Add, that ſince Jupiter's ſatellites revolve in times that are in a ſeſquiplicate ratio of their diſtances from the center of Jupiter, and conſequently at equal diſtances from Jupiter, their accelerating gravities are equal; therefore, falling equal altitudes in equal times, they will deſcribe equal ſpaces; juſt as in heavy bodies on our earth. And the ſame argument will hold of the primary planets with regard to the ſun, and the powers whereby unequal bodies are equally accelerated, are as the bodies, that is, the weights are as the quantities of matter in the planets, and the weights of the primary and ſecondary planets towards the ſun, are as the quantities of matter in the planets and ſatellites. See JUPITER.

And hence are ſeveral corollaries drawn relating to the weights of bodies on the ſurface of the earth, magnetiſm, and the exiſtence of a vacuum. See WEIGHT and MAGNET.

5. Gravity extends itſelf towards all bodies, and is in proportion to the quantity of matter in each.

That all planets gravitate towards each other, has been already ſhewn; likewiſe, that the gravity towards any

one, conſidered apart, is reciprocally as the ſquares of its diſtance from the center of the planet; conſequently, gravity is proportionable to the matter therein. Further, as all the parts of any planet, A, gravitate towards another planet B; and the gravity of any part is to the gravity of the whole, as the matter of the part to the matter of the whole; and re-action equal to action: the planet B will gravitate towards all the parts of the planet A; and its gravity towards any part will be to its gravity towards the whole, as the matter of the part to the matter of the whole. Hence we derive the methods of finding and comparing weights of bodies towards different planets; of finding the quantity of matter in the ſeveral planets, and their denſities; ſince the weights of equal bodies, revolving about planets, are as the diameters of their orbits directly, and as the ſquares of the periodical times inverſely; and the weights at any diſtance from the center of the planet are greater or leſs in a duplicate ratio of their diſtances inverſely: and ſince the quantities of matter in the planets are as their powers at equal diſtances from their centers: and laſtly, ſince the weights of equal and homogeneous bodies towards homogeneous ſpheres are, at the ſurfaces of the ſpheres, as the diameters of thoſe ſpheres; conſequently, the denſities of heterogeneous bodies are as the weights at the diameters of the ſpheres.

6. The common center of gravity of the ſun and all the planets is at reſt; and the ſun, though always in motion, yet never recedes far from the common center of all the planets.

For the matter in the ſun being to that in Jupiter as 1033 to 1; and Jupiter's diſtance from the ſun to the ſemidiameter of the ſun in a ratio ſomewhat bigger; the common center of gravity of Jupiter and the ſun will be a point a little without the ſun's ſurface; and by the ſame means, the common center of Saturn and the ſun will be a point a little within the ſun's ſurface; and the common center of the earth, and all the planets, will be ſcarce one diameter of the ſun diſtant from the center thereof: but the center is always at reſt; therefore, though the ſun will have a motion this and that way, according to the various ſituations of the planets, yet it can never recede far from the center; ſo that the common center of gravity of the earth, ſun, and planets, may be eſteemed the center of the whole world. See the article PLANET.
